- Use only pasteurized juices and dairy products; avoid Mexican soft cheeses, feta cheese, brie, Camembert, and blue-veined cheeses such as Roquefort.
- Thoroughly cook meat, poultry, eggs, and seafood.
- Thoroughly reheat hot dogs, luncheon meats, and deli meats, including cured meats such as salami.
- Wash all fruits and vegetables.
- Avoid refrigerated pâté, meat spreads, smoked seafood such as salmon or trout, and any fish labeled "nova," "lox," or "kippered," unless prepared in a cooked dish.

Dietary Guidelines for Americans 2005

- Pregnant women should not eat or drink unpasteurized milk, milk products, or juices; raw or undercooked eggs, meat, or poultry; or raw sprouts.
- Pregnant women should only eat certain deli meats and frankfurters that have been reheated to steaming hot.

Vitamin-Mineral Megadoses The pregnant woman who is trying to eat well may mistakenly assume that more is better when it comes to vitamin-mineral supplements. This is simply not true; many vitamins and minerals are toxic when taken

sudden infant death syndrome (SIDS): the unexpected and unexplained death of an apparently well infant; the most common cause of death of infants between the second week and the end of the first year of life; also called *crib death*.

listeriosis: an infection caused by eating food contaminated with the bacterium *Listeria monocytogenes,* which can be killed by pasteurization and cooking but can survive at refrigerated temperatures; certain ready-to-eat foods, such as hot dogs and deli meats, may become contaminated after cooking or processing, but before packaging.

in excess. Excessive vitamin A is particularly infamous for its role in malformations of the cranial nervous system. Intakes before the seventh week appear to be the most damaging. (Review Figure 14-4 on p. 480 to see how many tissues are in their critical periods prior to the seventh week.) For this reason, vitamin A supplements are not given during pregnancy unless there is specific evidence of deficiency, which is rare. A pregnant woman can obtain all the vitamin A and most of the other vitamins and minerals she needs by making wise food choices. She should take supplements only on the advice of a registered dietitian or physician.

Caffeine Caffeine crosses the placenta, and the developing fetus has a limited ability to metabolize it. Research studies have not proved that caffeine (even in high doses) causes birth defects in human infants (as it does in animals), but some evidence suggests that heavy use increases the risk of fetal death.[66] (In these studies, heavy caffeine use is defined as the equivalent of eight or more cups of coffee a day.) All things considered, it is most sensible to limit caffeine consumption to the equivalent of a cup of coffee or two 12-ounce cola beverages a day. (The caffeine contents of selected beverages, foods, and drugs are listed at the beginning of Appendix H.)

Weight-Loss Dieting Weight-loss dieting, even for short periods, is hazardous during pregnancy. Low-carbohydrate diets or fasts that cause ketosis deprive the fetal brain of needed glucose and may impair cognitive development. Such diets are also likely to lack other nutrients vital to fetal growth. Regardless of prepregnancy weight, pregnant women should never intentionally lose weight.

Sugar Substitutes Artificial sweeteners have been extensively investigated and found to be acceptable during pregnancy if used within the FDA's guidelines (presented in Highlight 4).[67] Still, it is prudent for pregnant women to use sweeteners in moderation and within an otherwise nutritious and well-balanced diet. Women with phenylketonuria should not use aspartame, as Highlight 4 explained.

IN SUMMARY

High-risk pregnancies, especially for teenagers, threaten the life and health of both mother and infant. Proper nutrition and abstinence from smoking, alcohol, and other drugs improve the outcome. In addition, prenatal care includes monitoring pregnant women for gestational diabetes and preeclampsia.

In general, the following guidelines will allow most women to enjoy a healthy pregnancy:[68]

- Get prenatal care.
- Eat a balanced diet, safely prepared.
- Take prenatal supplements as prescribed.
- Gain a healthy amount of weight.
- Refrain from cigarettes, alcohol, and drugs (including herbs, unless prescribed by a physician).

Childbirth marks the end of pregnancy and the beginning of a new set of parental responsibilities—including feeding the newborn.

Nutrition during Lactation

◆ To learn about breastfeeding, a pregnant woman can read at least one of the many books available. At the end of this chapter, Nutrition on the Net provides a list of resources, including LaLeche League International.

Before the end of her pregnancy, a woman needs to consider whether to feed her infant breast milk, ◆ infant formula, or both. These options are the only recommended foods for an infant during the first four to six months of life. The rate of breastfeeding is close to the Healthy People 2010 goal of 75 percent at birth, but it falls far short of goals at six months and a year.[69] This section focuses on how the

mother's nutrition supports the making of breast milk, and the next chapter describes how the infant benefits from drinking breast milk.

In many countries around the world, a woman breastfeeds her newborn without considering the alternatives or making a conscious decision. In other parts of the world, a woman feeds her newborn formula simply because she knows so little about breastfeeding. She may have misconceptions or feel uncomfortable about a process she has never seen or experienced. Breastfeeding offers many health benefits to both mother and infant, and every pregnant woman should seriously consider it (see Table 14-4).[70] Even so, there are sometimes valid reasons for not breastfeeding, and formula-fed infants grow and develop into healthy children.

© Ariel Skelley/CORBIS

A women who decides to breastfeed offers her infant a full array of nutrients and protective factors to support optimal health and development.

Lactation: A Physiological Process

Lactation naturally follows pregnancy, as the mother's body continues to nourish the infant. The **mammary glands** secrete milk for this purpose. The mammary glands develop during puberty but remain fairly inactive until pregnancy. During pregnancy, hormones promote the growth and branching of a duct system in the breasts and the development of the milk-producing cells.

The hormones **prolactin** and **oxytocin** finely coordinate lactation. The infant's demand for milk stimulates the release of these hormones, which signal the mammary glands to supply milk. Prolactin is responsible for milk production. As long as the infant is nursing, prolactin concentrations remain high, and milk production continues.

The hormone oxytocin causes the mammary glands to eject milk into the ducts, a response known as the **let-down reflex.** The mother feels this reflex as a contraction of the breast, followed by the flow of milk and the release of pressure. By relaxing and eating well, the nursing mother promotes easy let-down of milk and greatly enhances her chances of successful lactation.

TABLE 14-4 Benefits of Breastfeeding

For Infants:

- Provides the appropriate composition and balance of nutrients with high bioavailability
- Provides hormones that promote physiological development
- Improves cognitive development
- Protects against a variety of infections
- May protect against some chronic diseases, such as diabetes (both types), obesity, atherosclerosis, asthma, and hypertension, later in life
- Protects against food allergies

For Mothers:

- Contracts the uterus
- Delays the return of regular ovulation, thus lengthening birth intervals (is not, however, a dependable method of contraception)
- Conserves iron stores (by prolonging amenorrhea)
- May protect against breast and ovarian cancer and reduce the risk of diabetes (type 2)

Other:

- Cost savings from not needing medical treatment for childhood illnesses or time off work to care for them
- Cost savings from not needing to purchase formula (even after adjusting for added foods in the diet of a lactating mother)[a]
- Environmental savings to society from not needing to manufacture, package, and ship formula and dispose of the packaging
- Convenience of not having to shop for and prepare formula

[a]A nursing mother produces more than 35 gallons of milk during the first six months, saving roughly $450 in formula costs.

lactation: production and secretion of breast milk for the purpose of nourishing an infant.

mammary glands: glands of the female breast that secrete milk.

prolactin (pro-LAK-tin): a hormone secreted from the anterior pituitary gland that acts on the mammary glands to promote the production of milk. The release of prolactin is mediated by **prolactin-inhibiting hormone (PIH).**
- **pro** = promote
- **lacto** = milk

oxytocin (OCK-see-TOH-sin): a hormone that stimulates the mammary glands to eject milk during lactation and the uterus to contract during childbirth.

let-down reflex: the reflex that forces milk to the front of the breast when the infant begins to nurse.

Breastfeeding: A Learned Behavior

Lactation is an automatic physiological process that virtually all mothers are capable of doing. Breastfeeding, on the other hand, is a learned behavior that not all mothers decide to do. Of women who do breastfeed, those who receive early and repeated information and support breastfeed their infants longer than others. Health care professionals ◆ play an important role in providing encouragement and accurate information on breastfeeding.[71] Women who have been successful breastfeeding can offer advice and dispel misperceptions about lifestyle issues. Table 14-5 lists ten steps maternity facilities and health care professionals can take to promote successful breastfeeding among new mothers.[72]

◆ Some hospitals employ *certified lactation consultants* who specialize in helping new mothers establish a healthy breastfeeding relationship with their newborn. These consultants are often registered nurses with specialized training in breast and infant anatomy and physiology.

The mother's partner also plays an important role in encouraging breastfeeding.[73] When partners support the decision, mothers are more likely to start and continue breastfeeding. Clearly, educating those closest to the mother could change attitudes and promote breastfeeding.

Most healthy women who want to breastfeed can do so with a little preparation. Physical obstacles to breastfeeding are rare, although most nursing mothers quit before the recommended six months because of perceived difficulties.[74] Obese mothers seem to have a particularly difficult time, perhaps because of reduced prolactin levels.[75] Successful breastfeeding requires adequate nutrition and rest. This, plus the support of all who care, will help to enhance the well-being of mother and infant.

Maternal Energy and Nutrient Needs during Lactation

Ideally, the mother who chooses to breastfeed her infant will continue to eat nutrient-dense foods throughout lactation. An adequate diet is needed to support the stamina, patience, and self-confidence that nursing an infant demands.

Energy Intake and Exercise A nursing mother produces about 25 ounces of milk per day, with considerable variation from woman to woman and in the same woman from time to time, depending primarily on the infant's demand for milk. To produce an adequate supply of milk, a woman needs extra energy—almost 500

A jog through the park provides an opportunity for physical activity and fresh air.

TABLE 14-5 Ten Steps to Successful Breastfeeding

To promote breastfeeding, every maternity facility should:

- Develop a written breastfeeding policy that is routinely communicated to all health care staff
- Train all health care staff in the skills necessary to implement the breastfeeding policy
- Inform all pregnant women about the benefits and management of breastfeeding
- Help mothers initiate breastfeeding within ½ hour of birth
- Show mothers how to breastfeed and how to maintain lactation, even if they need to be separated from their infants
- Give newborn infants no food or drink other than breast milk, unless medically indicated
- Practice rooming-in, allowing mothers and infants to remain together 24 hours a day
- Encourage breastfeeding on demand
- Give no artificial nipples or pacifiers to breastfeeding infants[a]
- Foster the establishment of breastfeeding support groups and refer mothers to them at discharge from the facility

[a]Compared with nonusers, infants who use pacifiers breastfeed less frequently and stop breastfeeding at a younger age. C. G. Victora and coauthors, Pacifier use and short breastfeeding duration: Cause, consequence, or coincidence? *Pediatrics* 99 (1997): 445–453.

SOURCE: United Nations Children's Fund and World Health Organization, *Protecting, Promoting and Supporting Breastfeeding: The Special Role of Maternity Services.*

kcalories a day above her regular need during the first six months of lactation. To meet this energy need, ◆ she can eat an extra 330 kcalories of food each day and let the fat reserves she accumulated during pregnancy provide the rest. Most women need at least 1800 kcalories a day to receive all the nutrients required for successful lactation. Severe energy restriction may hinder milk production.

◆ Energy requirement during lactation:
- 1st 6 mo: +330 kcal/day
- 2nd 6 mo: +400 kcal/day

After the birth of the infant, many women actively try to lose the extra weight and body fat they accumulated during pregnancy.[76] Opinions differ as to whether breastfeeding helps with postpartum weight loss. Lactating women may lose body *fat* more slowly than nonlactating women, but the rate of *weight* loss is about the same.[77] In general, most women lose one to two pounds a month during the first four to six months of lactation; some may lose more, and others may maintain or even gain weight. Neither the quality nor the quantity of breast milk is adversely affected by moderate weight loss, and infants grow normally.

Dietary Guidelines for Americans 2005

Moderate weight reduction is safe for breastfeeding women and does not compromise weight gain of the nursing infant.

Women often exercise to lose weight and improve fitness, and this is compatible with breastfeeding and infant growth. Because intense physical activity can raise the lactate concentration of breast milk and influence the milk's taste, some infants may prefer milk produced prior to exercise. In these cases, mothers can either breastfeed before exercise or express their milk before exercise for use afterward.

Dietary Guidelines for Americans 2005

Neither acute nor regular exercise adversely affects the mother's ability to successfully breastfeed.

Energy Nutrients Recommendations for protein and fatty acids intakes remain about the same during lactation as during pregnancy, but they increase for carbohydrates and fibers. Nursing mothers need additional carbohydrate to replace the glucose used to make the lactose in breast milk. The fiber recommendation is 1 gram higher simply because it is based on kcalorie intake, which increases during lactation.

Vitamins and Minerals A question often raised is whether a mother's milk may lack a nutrient if she fails to get enough in her diet. The answer differs from one nutrient to the next, but in general, nutritional inadequacies reduce the *quantity,* not the *quality,* of breast milk. Women can produce milk with adequate protein, carbohydrate, fat, and most minerals, even when their own supplies are limited. For these nutrients and for the vitamin folate as well, milk quality is maintained at the expense of maternal stores. This is most evident in the case of calcium: dietary calcium has no effect on the calcium concentration of breast milk, but maternal bones lose some density during lactation if calcium intakes are inadequate.[78] Bone density increases again when lactation ends; breastfeeding has no long-term harmful effects on bones.[79] The nutrients in breast milk that are most likely to decline in response to prolonged inadequate intakes are the vitamins—especially vitamins B_6, B_{12}, A, and D. Review Figure 14-10 (p. 489) to compare a lactating woman's nutrient needs with those of pregnant and nonpregnant women.

Water Despite misconceptions, a mother who drinks more fluid does not produce more breast milk. To protect herself from dehydration, however, a lactating woman

© Photodisc/Getty Images

Nutritious foods support successful lactation.

◆ AI for *total* water (including drinking water, other beverages, and foods) during lactation: 3.8 L/day

needs to drink plenty of fluids. ◆ A sensible guideline is to drink a glass of milk, juice, or water at each meal and each time the infant nurses.

Nutrient Supplements Most lactating women can obtain all the nutrients they need from a well-balanced diet without taking vitamin-mineral supplements. Nevertheless, some may need iron supplements, not to enhance the iron in their breast milk, but to refill their depleted iron stores. The mother's iron stores dwindle during pregnancy as she supplies the developing fetus with enough iron to last through the first four to six months of the infant's life. In addition, childbirth may have incurred blood losses. Thus a woman may need iron supplements during lactation even though, until menstruation resumes, her iron requirement is about half that of other nonpregnant women her age.

Food Assistance Programs In general, women most likely to participate in the food assistance program WIC—those who are poor and have little education—are less likely to breastfeed. Furthermore, WIC provides infant formula at no cost. Because WIC recognizes the many benefits of breastfeeding, efforts are made to overcome this dilemma. In addition to nutrition education, breastfeeding mothers receive the following WIC incentives:

- Higher priority in certification into WIC
- Longer eligibility to participate in WIC
- More foods and larger quantities
- Breast pumps and other support materials

Together, these efforts help to provide nutrition support and encourage WIC mothers to breastfeed.

Particular Foods Foods with strong or spicy flavors (such as garlic) may alter the flavor of breast milk. A sudden change in the taste of the milk may annoy some infants. Familiar flavors may enhance enjoyment.

Infants who develop symptoms of food allergy may be more comfortable if the mother's diet excludes the most common offenders—cow's milk, eggs, fish, peanuts, and tree nuts. Generally, infants with a strong family history of food allergies benefit from breastfeeding.

A nursing mother can usually eat whatever nutritious foods she chooses. If she suspects a particular food is causing the infant discomfort, her physician may recommend a dietary challenge: eliminate the food from the diet to see if the infant's reactions subside; then return the food to the diet, and again monitor the infant's reactions. If a food must be eliminated for an extended time, appropriate substitutions must be made to ensure nutrient adequacy.

Maternal Health

If a woman has an ordinary cold, she can continue nursing without worry. If susceptible, the infant will catch it from her anyway. (Thanks to the immunological protection of breast milk, the baby may be less susceptible than a formula-fed baby would be.) With appropriate treatment, a woman who has an infectious disease such as tuberculosis or hepatitis can breastfeed; transmission is rare.[80] Women with HIV (human immunodeficiency virus) infections, however, should consider other options.

HIV Infection and AIDS Mothers with HIV infections can transmit the virus (which causes AIDS) to their infants through breast milk, especially during the early months of breastfeeding.[81] Where safe alternatives are available, HIV-positive women should *not* breastfeed their infants. In developing countries, where the feeding of inappropriate or contaminated formulas causes 1.5 million infant deaths each year, the decision is less obvious. To prevent the mother-to-child transmission of HIV, WHO and UNICEF urge mothers in developing countries *not* to breastfeed. However, they stress the importance of finding suitable feeding alternatives to pre-

vent the malnutrition, disease, and death that commonly occur when women in these countries do not breastfeed.

Diabetes Women with diabetes (type 1) may need careful monitoring and counseling to ensure successful lactation. These women need to adjust their energy intakes and insulin doses to meet the heightened needs of lactation. Maintaining good glucose control helps to initiate lactation and support milk production.

Postpartum Amenorrhea Women who breastfeed experience prolonged **postpartum amenorrhea.** Absent menstrual periods, however, do not protect a woman from pregnancy. To prevent pregnancy, a couple must use some form of contraception. Breastfeeding women who use oral contraceptives should use progestin-only agents for at least the first six months.[82] Estrogen-containing oral contraceptives reduce the volume and the protein content of breast milk.

Breast Health Some women fear that breastfeeding will cause their breasts to sag. The breasts do swell and become heavy and large immediately after the birth, but even when they produce enough milk to nourish a thriving infant, they eventually shrink back to their prepregnant size. Given proper support, diet, and exercise, breasts often return to their former shape and size when lactation ends. Breasts change their shape as the body ages, but breastfeeding does not accelerate this process.

Whether the physical and hormonal events of pregnancy and lactation protect women from later breast cancer is an area of active research.[83] Some research suggests no association between breastfeeding and breast cancer, whereas other research suggests a protective effect. Protection against breast cancer is most apparent for premenopausal women who were young when they breastfed and who breastfed for a long time.

Practices Incompatible with Lactation

Some substances impair milk production or enter breast milk and interfere with infant development. This section discusses practices that a breastfeeding mother should avoid.

Alcohol Alcohol easily enters breast milk, and its concentration peaks within an hour of ingestion. Infants drink less breast milk when their mothers have consumed even small amounts of alcohol (equivalent to a can of beer). Three possible reasons, acting separately or together, may explain why. For one, the alcohol may have altered the flavor of the breast milk and thereby the infants' acceptance of it. For another, because infants metabolize alcohol inefficiently, even low doses may be potent enough to suppress their feeding and cause sleepiness. Third, the alcohol may have interfered with lactation by inhibiting the hormone oxytocin.

In the past, alcohol has been recommended to mothers to facilitate lactation despite a lack of scientific evidence that it does so. The research summarized here suggests that alcohol actually hinders breastfeeding. An occasional alcoholic beverage may be within safe limits, but breastfeeding should be avoided for at least two hours afterwards.

Medicinal Drugs Most medicines are compatible with breastfeeding, but some are contraindicated, either because they suppress lactation or because they are secreted into breast milk and can harm the infant.[84] As a precaution, a nursing mother should consult with her physician prior to taking any drug, including herbal supplements.

Illicit Drugs Illicit drugs, of course, are harmful to the physical and emotional health of both the mother and the nursing infant. Breast milk can deliver such high doses of illicit drugs as to cause irritability, tremors, hallucinations, and even death in infants. Women whose infants have overdosed on illicit drugs contained in breast milk have been convicted of murder.

postpartum amenorrhea: the normal temporary absence of menstrual periods immediately following childbirth.

Smoking Because cigarette smoking reduces milk volume, smokers may produce too little milk to meet their infants' energy needs. The milk they do produce contains nicotine, which alters its smell and flavor. Consequently, infants of breastfeeding mothers who smoke gain less weight than infants of those who do not smoke. Furthermore, infant exposure to passive smoke negates the protective effect breastfeeding offers against SIDS and increases the risks dramatically.

Environmental Contaminants Some environmental contaminants in the food supply, such as DDT, PCBs, and dioxin, can find their way into breast milk. Inuit mothers living in Arctic Québec who eat seal and beluga whale blubber have high concentrations of DDT and PCBs in their breast milk, but the impact on infant development is unclear. Preliminary studies indicate that the children of these Inuit mothers are developing normally. Researchers speculate that the abundant omega-3 fatty acids of the Inuit diet may protect against damage to the central nervous system. Breast milk tainted with dioxins interferes with tooth development during early infancy, producing soft, mottled teeth that are vulnerable to dental caries. To limit mercury intake, lactating women should heed the fish restrictions mentioned earlier for pregnant women (see p. 499).

Caffeine Caffeine enters breast milk and may make an infant irritable and wakeful. As during pregnancy, caffeine consumption should be moderate—the equivalent of one to two cups of coffee a day. Larger doses of caffeine may interfere with the bioavailability of iron from breast milk and impair the infant's iron status.

IN SUMMARY

The lactating woman needs extra fluid and enough energy and nutrients to produce about 25 ounces of milk a day. Breastfeeding is contraindicated for those with HIV/AIDS. Alcohol, other drugs, smoking, and contaminants may reduce milk production or enter breast milk and impair infant development.

This chapter has focused on the nutrition needs of the mother during pregnancy and lactation. The next chapter explores the dietary needs of infants, children, and adolescents.

Nutrition Portfolio

The choices a woman makes in preparation for, and in support of, pregnancy and lactation can influence both her health and her infant's development—today and for decades to come.

- For women of childbearing age, determine whether you consume at least 400 micrograms of dietary folate equivalents daily.
- For women who are pregnant, evaluate whether you are meeting your nutrition needs and gaining the amount of weight recommended.
- For women who are about to give birth, carefully consider all the advantages of breastfeeding your infant and obtain the needed advice to support you.

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Describe the placenta and its function. (p. 478–479)
2. Describe the normal events of fetal development. How does malnutrition impair fetal development? (pp. 478–480, 495)
3. Define the term *critical period*. How do adverse influences during critical periods affect later health? (pp. 480–483)
4. Explain why women of childbearing age need folate in their diets. How much is recommended, and how can women ensure that these needs are met? (pp. 481–483)
5. What is the recommended pattern of weight gain during pregnancy for a woman at a healthy weight? For an underweight woman? For an overweight woman? (pp. 484–486)
6. What does a pregnant woman need to know about exercise? (pp. 486–487)
7. Which nutrients are needed in the greatest amounts during pregnancy? Why are they so important? Describe wise food choices for the pregnant woman. (pp. 487–491)
8. Define low-risk and high-risk pregnancies. What is the significance of infant birthweight in terms of the child's future health? (pp. 493–495)
9. Describe some of the special problems of the pregnant adolescent. Which nutrients are needed in increased amounts? (p. 497)
10. What practices should be avoided during pregnancy? Why? (pp. 498–500)
11. How do nutrient needs during lactation differ from nutrient needs during pregnancy? (pp. 489, 502–504)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 510.

1. The spongy structure that delivers nutrients to the fetus and returns waste products to the mother is called the:
   a. embryo.
   b. uterus.
   c. placenta.
   d. amniotic sac.
2. Which of these strategies is *not* a healthy option for an overweight woman?
   a. Limit weight gain during pregnancy.
   b. Postpone weight loss until after pregnancy.
   c. Follow a weight-loss diet during pregnancy.
   d. Try to achieve a healthy weight before becoming pregnant.
3. A reasonable weight gain during pregnancy for a normal-weight woman is about:
   a. 10 pounds.
   b. 20 pounds.
   c. 30 pounds.
   d. 40 pounds.
4. Energy needs during pregnancy increase by about:
   a. 100 kcalories/day.
   b. 300 kcalories/day.
   c. 500 kcalories/day.
   d. 700 kcalories/day.

5. To help prevent neural tube defects, grain products are now fortified with:
   a. iron.
   b. folate.
   c. protein.
   d. vitamin C.
6. Pregnant women should *not* take supplements of:
   a. iron.
   b. folate.
   c. vitamin A.
   d. vitamin C.
7. The combination of high blood pressure, protein in the urine, and edema signals:
   a. jaundice.
   b. preeclampsia.
   c. gestational diabetes.
   d. gestational hypertension.
8. To facilitate lactation, a mother needs:
   a. about 5000 kcalories a day.
   b. adequate nutrition and rest.
   c. vitamin and mineral supplements.
   d. a glass of wine or beer before each feeding.
9. A breastfeeding woman should drink plenty of water to:
   a. produce more milk.
   b. suppress lactation.
   c. prevent dehydration.
   d. dilute nutrient concentration.
10. A woman may need iron supplements during lactation:
    a. to enhance the iron in her breast milk.
    b. to provide iron for the infant's growth.
    c. to replace the iron in her body's stores.
    d. to support the increase in her blood volume.

Fetal Alcohol Syndrome

© Streissguth, A. P./Landesman-Dwyer, S., Martin, J. C., & Smith, D. W.

As Chapter 14 mentioned, drinking alcohol during pregnancy endangers the fetus. Alcohol crosses the placenta freely and deprives the developing fetus of both nutrients and oxygen. The damaging effects of alcohol on the developing fetus cover a range of abnormalities referred to as **fetal alcohol spectrum disorder** (see the glossary on p. 512).[1] Those at the most severe end of the spectrum are described as having **fetal alcohol syndrome (FAS)**, a cluster of physical, mental, and neurobehavioral symptoms that includes:

- Prenatal and postnatal growth retardation
- Impairment of the brain and central nervous system, with consequent mental retardation, poor motor skills and coordination, and hyperactivity
- Abnormalities of the face and skull (see Figure H14-1)
- Increased frequency of major birth defects: cleft palate, heart defects, and defects in ears, eyes, genitals, and urinary system

Tragically, the damage evident at birth persists: children with FAS never fully recover.[2]

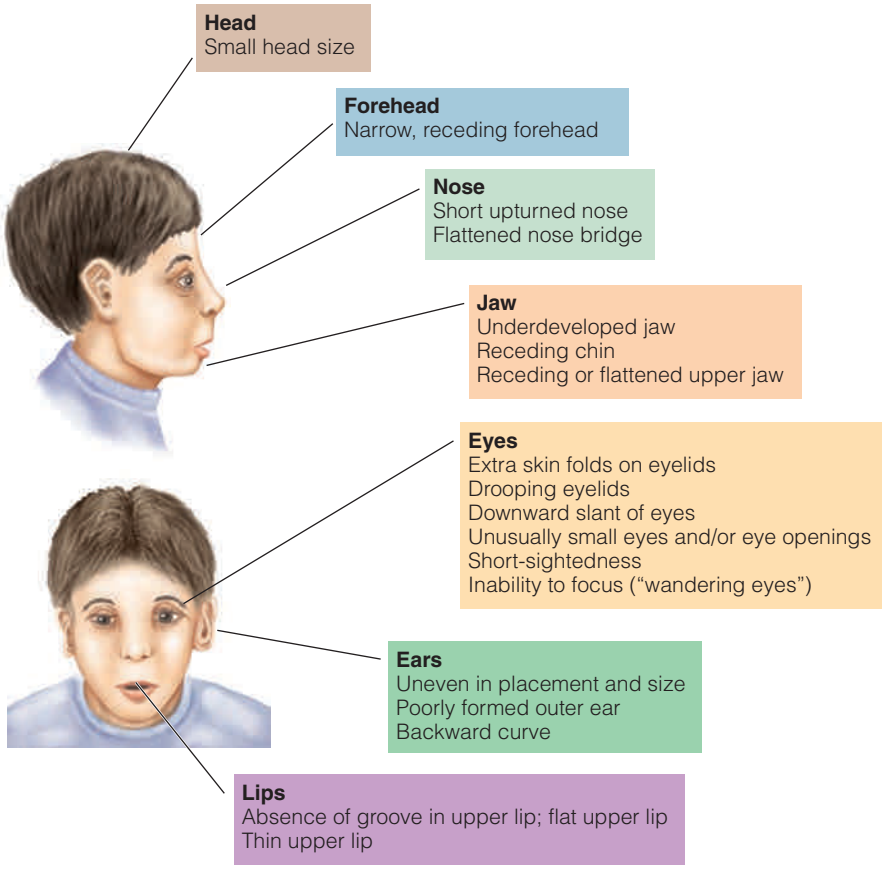
Each year, as many as 6000 infants are born with FAS because their mothers drank too much alcohol during pregnancy.[3] In addition, some 4 million infants are born with **prenatal alcohol exposure.** The cluster of mental problems associated with prenatal alcohol exposure is known as **alcohol-related neurodevelopmental disorder (ARND),** and the physical malformations are referred to as **alcohol-related birth defects (ARBD).** Some children with ARBD and ARND have no outward signs; others may be short or have only minor facial abnormalities. They often go undiagnosed even when they develop learning difficulties in the early school years. Mood disorders and problem behaviors, such as aggression, are common.[4]

The surgeon general states that pregnant women should abstain from alcohol. Abstinence from alcohol is the best policy for pregnant women both because alcohol consumption during pregnancy has such severe consequences and because FAS can only be prevented—it cannot be treated. Further, because the most severe damage occurs around the time of conception—*before a woman may even realize that she is pregnant*—the warning to abstain includes women who may become pregnant.

Drinking during Pregnancy

As mentioned in Chapter 14, 1 out of 10 pregnant women drinks alcohol at some time during her pregnancy; 1 out of 50 uses alcohol frequently and admits to binge drinking.[5] When a woman drinks during pregnancy, she causes damage in two ways: directly, by intoxication, and indirectly, by malnutrition. Prior to the

FIGURE H14-1 Typical Facial Characteristics of FAS



© Ellen B. Senisi/The Image Works

Characteristic facial features may diminish with time, but children with FAS typically continue to be short and underweight for their age.

complete formation of the placenta (approximately 12 weeks), alcohol diffuses directly into the tissues of the developing embryo, causing incredible damage. (Review Figure 14-4 on p. 480 and note that the critical periods for most tissues occur during embryonic development.) Alcohol interferes with the orderly development of tissues during their critical periods, reducing the number of cells and damaging those that are produced. The damage of alcohol toxicity during brain development is apparent in its reduced size and impaired function.[6]

When alcohol crosses the placenta, fetal blood alcohol rises until it reaches equilibrium with maternal blood alcohol. The mother may not even appear drunk, but the fetus may be poisoned. The fetus's body is small, its detoxification system is immature, and alcohol remains in fetal blood long after it has disappeared from maternal blood.

A pregnant woman harms her unborn child not only by consuming alcohol but also by not consuming food. This combination enhances the likelihood of malnutrition and a poorly developed infant. It is important to realize, however, that malnutrition is not the cause of FAS. It is true that mothers of FAS children often have unbalanced diets and nutrient deficiencies. It is also true that malnutrition may augment the clinical signs seen in these children, but it is the *alcohol* that causes the damage. An adequate diet alone will not prevent FAS if alcohol abuse continues.

How Much Is Too Much?

A pregnant woman need not have an alcohol-abuse problem to give birth to a baby with FAS. She need only drink in excess of her liver's capacity to detoxify alcohol. Even one drink a day threatens neurological development and behaviors.[7] Four drinks a day dramatically increase the risk of having an infant with physical malformations.

In addition to total alcohol intake, drinking patterns play an important role. Most FAS studies report their findings in terms of average intake per day, but people usually drink more heavily on some days than on others. For example, a woman who drinks an *average* of 1 ounce of alcohol (2 drinks) a day may not drink at all during the week, but then have 10 drinks on Saturday night, exposing the fetus to extremely toxic quantities of alcohol. Whether various drinking patterns incur damage depends on the frequency of consumption, the quantity consumed, and the stage of fetal development at the time of each drinking episode.

An occasional drink may be innocuous, but researchers are unable to say how much alcohol is safe to consume during pregnancy. For this reason, health care professionals urge women to stop drinking alcohol as soon as they realize they are pregnant or better, as soon as they *plan* to become pregnant. Why take any risk? Only the woman who abstains is sure of protecting her infant from FAS.

When Is the Damage Done?

The first month or two of pregnancy is a critical period of fetal development. Because pregnancy usually cannot be confirmed before five to six weeks, a woman may not even realize she is pregnant during that critical time. Therefore, it is advisable for women who are trying to conceive, or who suspect they might be pregnant, to abstain or curtail their alcohol intakes to ensure a healthy start.

The type of abnormality observed in an FAS infant depends on the developmental events occurring at the times of alcohol exposure. During the first trimester, developing organs such as the brain, heart, and kidneys may be malformed. During the second trimester, the risk of spontaneous abortion increases. During the third trimester, body and brain growth may be retarded.

GLOSSARY

alcohol-related birth defects (ARBD): malformations in the skeletal and organ systems (heart, kidneys, eyes, ears) associated with prenatal alcohol exposure.

alcohol-related neurodevelopmental disorder (ARND): abnormalities in the central nervous system and cognitive development associated with prenatal alcohol exposure.

fetal alcohol spectrum disorder: a range of physical, behavioral, and cognitive abnormalities caused by prenatal alcohol exposure.

fetal alcohol syndrome (FAS): a cluster of physical, behavioral, and cognitive abnormalities associated with prenatal alcohol exposure, including facial malformations, growth retardation, and central nervous disorders.

prenatal alcohol exposure: subjecting a fetus to a pattern of excessive alcohol intake characterized by substantial regular use or heavy episodic drinking.

NOTE: See Highlight 7 for other alcohol-related terms and information.

© 1995 George Steinmetz

Children born with FAS must live with the long-term consequences of prenatal brain damage.

Male alcohol ingestion may also affect fertility and fetal development.[8] Animal studies have found smaller litter sizes, lower birthweights, reduced survival rates, and impaired learning ability in the offspring of males consuming alcohol prior to conception. An association between paternal alcohol intake one month prior to conception and low infant birthweight is also apparent in human beings. (Paternal alcohol intake was defined as an average of 2 or more drinks daily or at least 5 drinks on one occasion.) This relationship was independent of either parent's smoking and of the mother's use of alcohol, caffeine, or other drugs.

In view of the damage caused by FAS, prevention efforts focus on educating women not to drink during pregnancy.[9] Everyone should know of the potential dangers. Women who drink alcohol and who are sexually active may benefit from counseling and effective contraception to prevent pregnancy.[10] Almost half of all pregnancies are unintended, with many conceived during a binge-drinking episode.[11]

Matthew Farruggio

All containers of beer, wine, and liquor warn women not to drink alcoholic beverages during pregnancy because of the risk of birth defects.

Public service announcements and alcohol beverage warning labels help to raise awareness. Everyone should hear the message loud and clear: Don't drink alcohol prior to conception or during pregnancy.

Nutrition in Your Life

Much of this book has focused on you—your food choices and how they might affect your health. This chapter shifts the focus from you the recipient to you the caregiver. One day (if not already), children will depend on you to feed them well and teach them wisely. The responsibility of nourishing children can seem overwhelming at times, but the job is fairly simple. Offer children a variety of nutritious foods to support their growth, and teach them how to make healthy food and activity choices. Presenting foods in a relaxed and supportive environment nourishes both physical and emotional well-being.

How To: Practice Problems

Nutrition Portfolio Journal

CHAPTER 15

Life Cycle Nutrition: Infancy, Childhood, and Adolescence

CHAPTER OUTLINE

Nutrition during Infancy • Energy and Nutrient Needs • Breast Milk • Infant Formula • Special Needs of Preterm Infants • Introducing Cow's Milk • Introducing Solid Foods • Mealtimes with Toddlers

Nutrition during Childhood • Energy and Nutrient Needs • Hunger and Malnutrition in Children • The Malnutrition-Lead Connection • Hyperactivity and "Hyper" Behavior • Food Allergy and Intolerance • Childhood Obesity • Mealtimes at Home • Nutrition at School

Nutrition during Adolescence • Growth and Development • Energy and Nutrient Needs • Food Choices and Health Habits • Problems Adolescents Face

HIGHLIGHT 15 Childhood Obesity and the Early Development of Chronic Diseases

The first year of life is a time of phenomenal growth and development. After the first year, a child continues to grow and change, but more slowly. Still, the cumulative effects over the next decade are remarkable. Then, as the child enters the teen years, the pace toward adulthood accelerates dramatically. This chapter examines the special nutrient needs of infants, children, and adolescents.

Nutrition during Infancy

Initially, the infant drinks only breast milk or formula but later begins to eat some foods, as appropriate. Common sense in the selection of infant foods along with a nurturing, relaxed environment support an infant's health and well-being.

Energy and Nutrient Needs

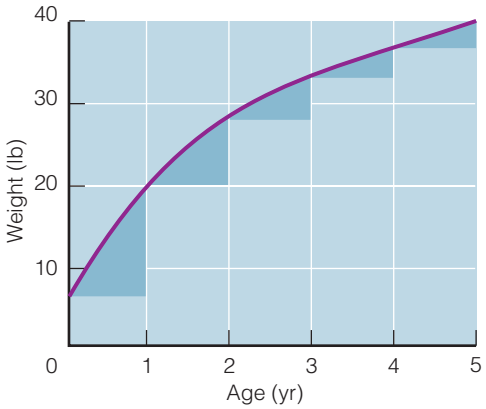
An infant grows fast during the first year, as Figure 15-1 shows. Growth directly reflects nutrient intake and is an important parameter in assessing the nutrition status of infants and children. Health care professionals measure the heights and weights of infants and children at intervals and compare the measurements with standard growth curves for gender and age and with previous measures of each child (see the "How to," p. 516).

Energy Intake and Activity A healthy infant's birthweight doubles by about five months of age and triples by one year, typically reaching 20 to 25 pounds. The infant's length changes more slowly than weight, increasing about 10 inches from birth to one year. By the end of the first year, infant growth slows considerably; during the second year, an infant typically gains less than 10 pounds and grows about 5 inches in height.

Not only do infants grow rapidly, but their energy requirement is remarkably high—about twice that of an adult, based on body weight. A newborn baby requires about 450 kcalories per day, whereas most adults require about 2000 kcalories per day. In terms of body weight, the difference is remarkable. Infants require about 100 kcalories per kilogram of body weight per day, whereas most adults need fewer than 40 (see Table 15-1, p. 516). If an infant's energy needs were applied to an adult, a 170-pound adult would require over 7000 kcalories a day. After six months, the infant's energy needs decline as the growth rate slows, but some of the energy saved by slower growth is spent in increased activity.

FIGURE 15-1 Weight Gain of Infants in Their First Five Years of Life

In the first year, an infant's birthweight may triple, but over the following several years, the rate of weight gain gradually diminishes.



HOW TO Plot Measures on a Growth Chart

You can assess the growth of infants and children by plotting their measurements on a percentile graph. Percentile graphs divide the measures of a population into 100 equal divisions so that half of the population falls at or above the 50th percentile and half falls below. Using percentiles allows for comparisons among people of the same age and gender.

To plot measures on a growth chart, follow these steps:

- Select the appropriate chart based on age and gender. For this example, use the accompanying chart, which gives percentiles for weight for girls from birth to 36 months. (Appendix E provides other growth charts for both boys and girls of various ages.)
- Locate the infant's age along the horizontal axis at the bottom of the chart (in this example, 6 months).
- Locate the infant's weight in pounds or kilograms along the vertical axis of the chart (in this example, 17 pounds or 7.7 kilograms).
- Mark the chart where the age and weight lines intersect (shown here with a red dot), and follow the curved line to find the percentile.

This six-month-old infant is at the 75th percentile. Her pediatrician will weigh her again over the next few months and expect the growth curve to follow the same percentile throughout the first year. In general, dramatic changes or measures much above the 80th percentile or much below the 10th percentile may be cause for concern.

TABLE 15-1 Infant and Adult Heart Rate, Respiration Rate, and Energy Needs Compared

	Infants	Adults
Heart rate (beats/minute)	120 to 140	70 to 80
Respiration rate (breaths/minute)	20 to 40	15 to 20
Energy needs (kcal/body weight)	45/lb (100/kg)	<18/lb (<40/kg)

Energy Nutrients Recommendations for the energy nutrients—carbohydrate, fat, and protein—during the first six months of life are based on the average intakes of healthy, full-term infants fed breast milk.[1] During the second six months of life, recommendations reflect typical intakes from solid foods as well as breast milk.

As discussed in Chapter 4, carbohydrates provide energy to all the cells of the body, especially those in the brain, which depend primarily on glucose to fuel activities. Relative to the size of the body, an infant's brain is larger and uses relatively more glucose—about 60 percent of the day's total energy intake.[2]

Fat provides most of the energy in breast milk and standard infant formula. Its high energy density supports the rapid growth of early infancy.

No single nutrient is more essential to growth than protein. All of the body's cells and most of its fluids contain protein; it is the basic building material of the body's tissues. Chapter 6 detailed the problems inadequate protein can cause. Excess dietary protein can cause problems, too, especially in a small infant. Too much protein stresses the liver and kidneys, which have to metabolize and excrete the excess nitrogen. Signs of protein overload include acidosis, dehydration, diarrhea, elevated blood ammonia, elevated blood urea, and fever. Such problems are not com-

mon, but they have been observed in infants fed inappropriate foods, such as fat-free milk or concentrated formula.

Vitamins and Minerals As with the energy nutrients, the recommendations for the vitamins and minerals are based on the average amount of nutrients consumed by thriving infants breastfed by well-nourished mothers. An infant's needs for most of these nutrients, in proportion to body weight, are more than double those of an adult. Figure 15-2 illustrates this by comparing a five-month-old infant's needs per unit of body weight with those of an adult man. Some of the differences are extraordinary.

Water One of the most essential nutrients for infants, as for everyone, is water. The younger the infant, the greater the percentage of body weight is water. During early infancy, breast milk or infant formula normally provides enough water to replace fluid losses in a healthy infant. Even in hot, dry climates, neither breastfed nor bottle-fed infants need supplemental water.[3] Because much of the fluid in an infant's body is located *outside* the cells—between the cells and in the blood vessels—rapid fluid losses and the resulting dehydration can be life-threatening. Conditions that cause rapid fluid loss, such as diarrhea or vomiting, require treatment with an electrolyte solution designed for infants.

David Lees/Getty Images

After six months, energy saved by slower growth is spent in increased activity.

FIGURE 15-2 Recommended Intakes of an Infant and an Adult Compared on the Basis of Body Weight

Because infants are small, they need smaller total amounts of the nutrients than adults do, but when comparisons are based on body weight, infants need more than twice as much of many nutrients. Infants use large amounts of energy and nutrients, in proportion to their body size, to keep all their metabolic processes going.

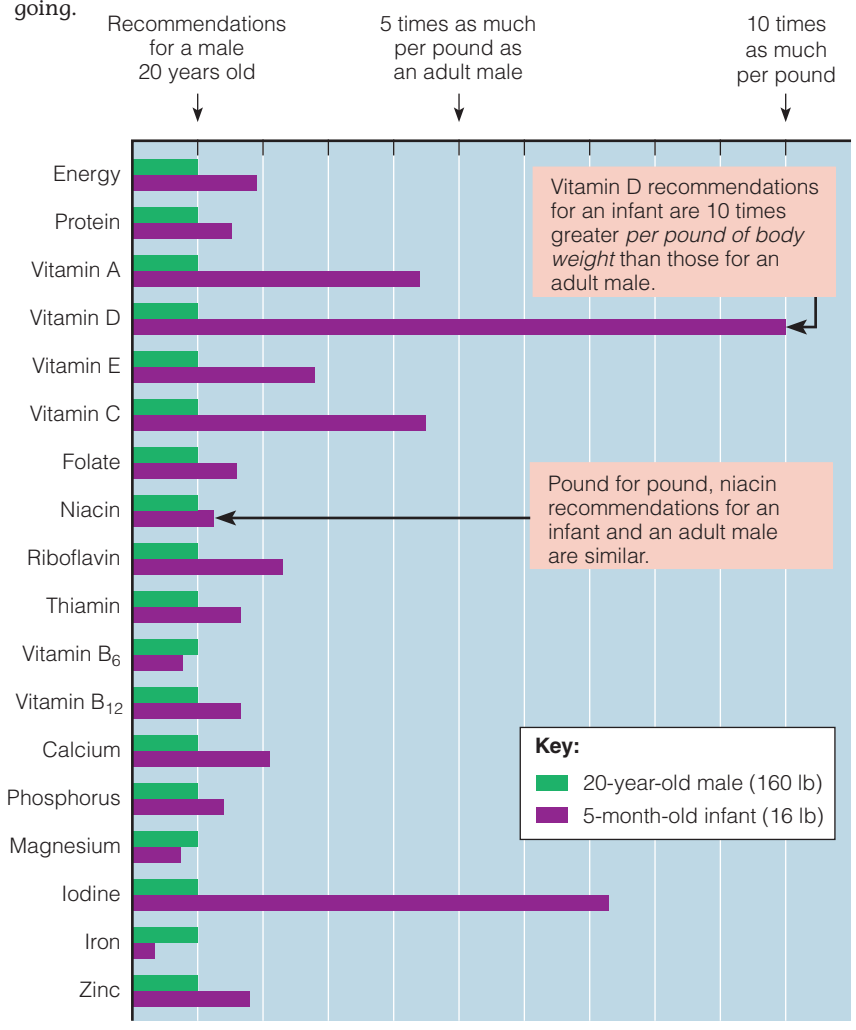

FIGURE 15-3 Percentages of Energy-Yielding Nutrients in Breast Milk and in Recommended Adult Diets

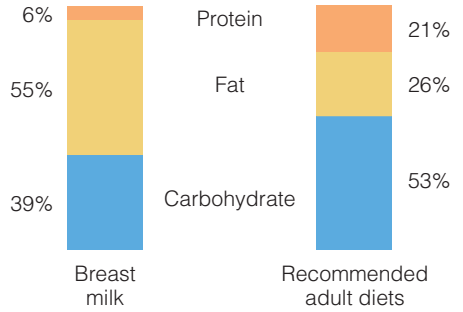
The proportions of energy-yielding nutrients in human breast milk differ from those recommended for adults.[a]



[a]The values listed for adults represent approximate midpoints of the acceptable ranges for protein (10 to 35 percent), fat (20 to 35 percent), and carbohydrate (45 to 65 percent).

◆ Chapter 14 discussed breastfeeding, breastfeeding support, reasons why some women choose not to breastfeed, and contraindications to breastfeeding.

Breast Milk

In the United States and Canada, the two dietary practices that have the most significant effect on an infant's nutrition are the milk the infant receives and the age at which solid foods are introduced. A later section discusses the introduction of solid foods, but as to the milk, both the American Academy of Pediatrics (AAP) and the Canadian Paediatric Society strongly recommend breastfeeding for healthy full-term infants, except where specific contraindications exist. The American Dietetic Association (ADA) also advocates breastfeeding for the nutritional health it confers on the infant as well as for the many other benefits it provides both infant and mother (review Table 14-4, p. 501).[4]

Breast milk excels as a source of nutrients for infants. Its unique nutrient composition and protective factors promote optimal infant health and development throughout the first year of life. The AAP, the Canadian Paediatric Society, and the ADA recommend exclusive breastfeeding for 6 months, and breastfeeding with complementary foods for at least 12 months for infants.[5] Experts add, though, that iron-fortified formula, which imitates the nutrient composition of breast milk, is an acceptable alternative. After all, the primary goal is to provide the infant nourishment in a relaxed and loving environment. ◆

Frequency and Duration of Breastfeeding Breast milk is more easily and completely digested than formula, so breastfed infants usually need to eat more frequently than formula-fed infants do. During the first few weeks, approximately 8 to 12 feedings a day, on demand, as soon as the infant shows early signs of hunger such as increased alertness, activity, or suckling motions, promote optimal milk production and infant growth.[6] Crying is a late indicator of hunger. An infant who nurses every two to three hours and sleeps contentedly between feedings is adequately nourished. As the infant gets older, stomach capacity enlarges and the mother's milk production increases, allowing for longer intervals between feedings.

Even though the infant obtains about half the milk from the breast during the first two or three minutes of sucking, breastfeeding is encouraged for about 10 to 15 minutes on each breast. The infant's sucking, as well as the complete removal of milk from the breast, stimulates lactation.

Energy Nutrients The energy-nutrient composition of breast milk differs dramatically from that recommended for adult diets (see Figure 15-3). Yet for infants, breast milk is nature's most nearly perfect food, providing the clear lesson that people at different stages of life have different nutrient needs.

The carbohydrate in breast milk (and infant formula) is the disaccharide lactose. In addition to being easily digested, lactose enhances calcium absorption.

The amount of protein in breast milk is less than in cow's milk, but this quantity is actually beneficial because it places less stress on the infant's immature kidneys to excrete the major end product of protein metabolism, urea. Much of the protein in breast milk is **alpha-lactalbumin**, which is efficiently digested and absorbed.

As for the lipids, breast milk contains a generous proportion of the essential fatty acids linoleic acid and linolenic acid, as well as their longer-chain derivatives arachidonic acid and DHA (docosahexaenoic acid). Infant formula used to provide only linoleic acid and linolenic acid, but now arachidonic acid and DHA are also included.[7] Infants can make arachidonic acid and DHA from linoleic and linolenic acid, respectively, but some infants may need more than they can make.

Arachidonic acid and DHA are found abundantly in both the retina of the eye and the brain, and research has focused on the visual and mental development of breastfed infants and infants fed standard formula without DHA and arachidonic acid added.[8] Breastfed infants generally score higher on tests of mental development than formula-fed infants do, and researchers are investigating whether this difference can be attributed to DHA and arachidonic acid in breast milk.[9] In one study, researchers found no developmental or visual differences between infants fed standard formula and those fed formula with added DHA and arachidonic acid.[10] In two other studies, however, infants fed the formula fortified with DHA and

alpha-lactalbumin (lact-AL-byoo-min): a major protein in human breast milk, as opposed to **casein** (CAY-seen), a major protein in cow's milk.

arachidonic acid formula had sharper vision at one year of age than those who were fed standard formula.[11]

Vitamins With the exception of vitamin D, the vitamins in breast milk are ample to support infant growth. The vitamin D in breast milk is low, and vitamin D deficiency impairs bone mineralization. Vitamin D deficiency is most likely in infants who are not exposed to sunlight daily, have darkly pigmented skin, and receive breast milk without vitamin D supplementation.[12] Reports of infants in the United States developing the vitamin D–deficiency disease rickets and recommendations by the AAP to keep infants under six months of age out of direct sunlight have prompted updated vitamin D guidelines. The AAP now recommends a vitamin D supplement for all infants who are breastfed exclusively, and for any infants who do not receive at least 500 milliliters (15 ounces) per day of vitamin D–fortified formula.[13]

Minerals The calcium content of breast milk is ideal for infant bone growth, and the calcium is well absorbed. Breast milk contains relatively small amounts of iron, but the iron has a high bioavailability. Zinc also has a high bioavailability, thanks to the presence of a zinc-binding protein. Breast milk is low in sodium, another benefit for immature kidneys. Fluoride promotes the development of strong teeth, but breast milk is not a good source.

Supplements Pediatricians may routinely prescribe liquid supplements containing vitamin D, iron, and fluoride. Table 15-2 offers a schedule of supplements during infancy. In addition, the AAP recommends giving a single dose of vitamin K to infants at birth to protect them from bleeding to death. (See Chapter 11 for a description of vitamin K's role in blood clotting.)

Immunological Protection In addition to nutritional benefits, breast milk offers immunological protection. Not only is breast milk sterile, but it actively fights disease and protects infants from illnesses.[14] Such protection is most valuable during the first year, when the infant's immune system is not fully prepared to mount a response against infection.

During the first two or three days after delivery, the breasts produce **colostrum**, a premilk substance containing mostly serum with antibodies and white blood cells. Colostrum (like breast milk) helps protect the newborn from infections against which the mother has developed immunity. The maternal antibodies swallowed with the milk inactivate disease-causing bacteria within the digestive tract before they can start infections. This explains, in part, why breastfed infants have fewer intestinal infections than formula-fed infants.

In addition to antibodies, colostrum and breast milk provide other powerful agents ◆ that help to fight against bacterial infection. Among them are **bifidus factors**, which favor the growth of the "friendly" bacterium *Lactobacillus bifidus*

© Jennie Woodcock; Reflections Photolibrary/Corbis

Women are encouraged to breastfeed whenever possible because breast milk offers infants many nutrient and health advantages.

◆ Protective factors in breast milk:
- Antibodies
- Bifidus factors
- Lactoferrin
- Lactadherin
- Growth factor
- Lipase enzyme

TABLE 15-2 Supplements for Full-Term Infants

	Vitamin D[a]	Iron[b]	Fluoride[c]
Breastfed infants:			
Birth to six months of age	✔		
Six months to one year	✔	✔	✔
Formula-fed infants:			
Birth to six months of age			
Six months to one year		✔	✔

[a]Vitamin D supplements are recommended for all infants who are exclusively breastfed and for any infants who do not receive at least 500 milliliters (15 ounces) of vitamin D–fortified formula.
[b]Infants four to six months of age need additional iron, preferably in the form of iron-fortified cereal for both breastfed and formula-fed infants and iron-fortified infant formula for formula-fed infants.
[c]At six months of age, breastfed infants and formula-fed infants who receive ready-to-use formulas (these are prepared with water low in fluoride) or formula mixed with water that contains little or no fluoride (less than 0.3 ppm) need supplements.
SOURCE: Adapted from Committee on Nutrition, American Academy of Pediatrics, *Pediatric Nutrition Handbook*, 5th ed., ed. R. E. Kleinman (Elk Grove Village, Ill.: American Academy of Pediatrics, 2004).

colostrum (ko-LAHS-trum): a milklike secretion from the breast, present during the first day or so after delivery before milk appears; rich in protective factors.

bifidus (BIFF-id-us, by-FEED-us) **factors:** factors in colostrum and breast milk that favor the growth of the "friendly" bacterium *Lactobacillus* (lack-toh-ba-SILL-us) *bifidus* in the infant's intestinal tract, so that other, less desirable intestinal inhabitants will not flourish.

in the infant's digestive tract, so that other, harmful bacteria cannot become established. An iron-binding protein in breast milk, **lactoferrin**, keeps bacteria from getting the iron they need to grow, helps absorb iron into the infant's bloodstream, and kills some bacteria directly.[15] The protein **lactadherin** in breast milk binds to, and inhibits replication of, the virus that causes most infant diarrhea.[16] Breastfeeding also protects against other common illnesses of infancy such as middle ear infection and respiratory illness.[17] In addition, a growth factor that is present in breast milk stimulates the development and maintenance of the infant's digestive tract and its protective factors. Several breast milk enzymes such as lipase also help protect the infant against infection. Clearly, breast milk is a very special substance.

Allergy and Disease Protection In addition to protection against infection, breast milk may offer protection against the development of allergies. Compared with formula-fed infants, breastfed infants have a lower incidence of allergic reactions, such as asthma, recurrent wheezing, and skin rash.[18] This protection is especially noticeable among infants with a family history of allergies.[19] Similarly, breast milk may offer protection against the development of cardiovascular disease. Compared with formula-fed infants, breastfed infants have lower blood pressure and lower blood cholesterol as adults.[20]

Other Potential Benefits Breastfeeding may also help protect against excessive weight gain later. A review of more than 60 published studies investigating the relationship between infant feeding and obesity suggests that initial breastfeeding protects against obesity in later life.[21] A well-controlled survey of more than 15,000 adolescents and their mothers indicated that those who were mostly breastfed for the first six months of life were less likely to become overweight than those who were fed formula.[22] A study of much younger children (three to five years of age), however, found no clear evidence that breastfeeding influences body weight.[23] These researchers noted that other factors, especially the mother's weight, strongly predict overweight in children.

Many studies suggest a beneficial effect of breastfeeding on intelligence, but when subjected to strict standards of methodology (for example, large sample size and appropriate intelligence testing), the evidence is less convincing.[24] Nevertheless, the possibility that breastfeeding may positively affect later intelligence is intriguing. It may be that some specific component of breast milk, such as DHA, stimulates brain development or that certain factors associated with the feeding process itself promote intellect. Most likely, a combination of factors are involved. More large, well-controlled studies are needed to confirm the effects, if any, of breastfeeding on later intelligence.

Breast Milk Banks Similar to blood banks that collect blood from individuals to give to others in need, **breast milk banks** receive milk from lactating women who have an abundant supply to give to infants whose own mothers' milk is unavailable or insufficient. The women who donate breast milk are carefully screened to exclude those who smoke cigarettes, use illegal drugs, take medications (including high doses of dietary supplements), drink more than two alcoholic beverages a day, or have communicable diseases. The breast milk from several donors is pooled to ensure an even distribution of all components, pasteurized to destroy bacteria, checked for contamination, and frozen before being shipped overnight to hospitals, where it is dispensed by physician prescription. In the absence of mother's own breast milk, donor milk may be the life-saving solution for fragile infants, most notably those with very low birthweight or unusual medical conditions.[25]

lactoferrin (lack-toh-FERR-in): a protein in breast milk that binds iron and keeps it from supporting the growth of the infant's intestinal bacteria.

lactadherin (lack-tad-HAIR-in): a protein in breast milk that attacks diarrhea-causing viruses.

breast milk bank: a service that collects, screens, processes, and distributes donated human milk.

wean: to gradually replace breast milk with infant formula or other foods appropriate to an infant's diet.

Infant Formula

A woman who breastfeeds for a year can **wean** her infant to cow's milk, bypassing the need for infant formula. However, a woman who decides to feed her infant for-

mula from birth, to wean to formula after less than a year of breastfeeding, or to substitute formula for breastfeeding on occasion must select an appropriate infant formula and learn to prepare it.

Infant Formula Composition Formula manufacturers attempt to copy the nutrient composition of breast milk as closely as possible. Figure 15-4 illustrates the energy-nutrient balance of both. The AAP recommends that all formula-fed infants receive iron-fortified infant formulas. The increasing use of iron-fortified formulas during the past few decades is a major reason for the decline in iron-deficiency anemia among U.S. infants.

Risks of Formula Feeding Infant formulas contain no protective antibodies for infants, but in general, vaccinations, purified water, and clean environments in developed countries help protect infants from infections. Formulas can be prepared safely by following the rules of proper food handling and by using water that is free of contamination. Of particular concern is lead-contaminated water, a major source of lead poisoning in infants. Because the first water drawn from the tap each day is highest in lead, a person living in a house with old, lead-soldered plumbing should let the water run a few minutes before drinking or using it to prepare formula or food.

In developing countries and in poor areas of the United States, formula may be unavailable, prepared with contaminated water, or overdiluted in an attempt to save money. Contaminated formulas often cause infections, leading to diarrhea, dehydration, and malabsorption. Without sterilization and refrigeration, formula is an ideal breeding ground for bacteria. Whenever such risks are present, breastfeeding can be a life-saving option: breast milk is sterile, and its antibodies enhance an infant's resistance to infections.

Infant Formula Standards National and international standards have been set for the nutrient contents of infant formulas. In the United States, the standard developed by the AAP reflects "human milk taken from well-nourished mothers during the first or second month of lactation, when the infant's growth rate is high." The Food and Drug Administration (FDA) mandates the safety and nutritional quality of infant formulas. Formulas meeting these standards have similar nutrient compositions. Small differences among formulas are sometimes confusing, but they are usually unimportant.

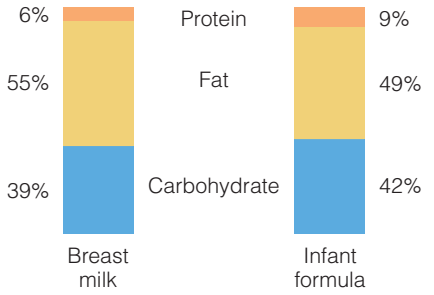
Special Formulas Standard cow's milk-based formulas are inappropriate for some infants. Special formulas have been designed to meet the dietary needs of infants with specific conditions such as prematurity or inherited diseases. Infants allergic to milk protein can drink special **hypoallergenic formulas** or formulas based on soy protein.[26] Soy formulas also use cornstarch and sucrose instead of lactose and so are recommended for infants with lactose intolerance as well. They are also useful as an alternative to milk-based formulas for vegan families. Despite these limited uses, soy formulas account for one-fourth of the infant formulas sold today. While soy formulas support the normal growth and development of infants, for infants who don't need them, they offer no advantage over milk formulas.

Inappropriate Formulas Caregivers must use only products designed for infants; soy *beverages,* for example, are nutritionally incomplete and inappropriate for infants. Goat's milk is also inappropriate for infants in part because of its low folate content. An infant receiving goat's milk is likely to develop "goat's milk anemia," an anemia characteristic of folate deficiency.

Nursing Bottle Tooth Decay An infant cannot be allowed to sleep with a bottle because of the potential damage to developing teeth. Salivary flow, which normally cleanses the mouth, diminishes as the infant falls asleep. Prolonged sucking on a bottle of formula, milk, or juice bathes the upper teeth in a carbohydrate-rich fluid that nourishes decay-producing bacteria. (The tongue covers and protects most of the lower teeth, but they, too, may be affected.) The result is extensive and rapid tooth decay (see Figure 15-5, p. 522). To prevent **nursing bottle tooth decay,** no infant should be put to bed with a bottle of nourishing fluid.

FIGURE 15-4 Percentages of Energy-Yielding Nutrients in Breast Milk and in Infant Formula

The average proportions of energy-yielding nutrients in human breast milk and formula differ slightly. In contrast, cow's milk provides too much protein (20%) and too little carbohydrate (30%).



© Jon Feingersh/Corbis

The infant thrives on infant formula offered with affection.

hypoallergenic formulas: clinically tested infant formulas that support infant growth and development but do not provoke reactions in 90% of infants or children with confirmed cow's milk allergy.

nursing bottle tooth decay: extensive tooth decay due to prolonged tooth contact with formula, milk, fruit juice, or other carbohydrate-rich liquid offered to an infant in a bottle.

FIGURE 15-5 Nursing Bottle Tooth Decay

This child was frequently put to bed sucking on a bottle filled with apple juice, so the teeth were bathed in carbohydrate for long periods of time—a perfect medium for bacterial growth. The upper teeth show signs of decay.

Special Needs of Preterm Infants

An estimated one out of eight pregnancies in the United States results in a preterm birth.[27] The terms *preterm* and *premature* imply incomplete fetal development, or immaturity, of many body systems. As might be expected, preterm birth is a leading cause of infant deaths. Preterm infants face physical independence from their mothers before some of their organs and body tissues are ready. The rate of weight gain in the fetus is greater during the last trimester of gestation than at any other time. Therefore, a preterm infant is most often a low-birthweight infant as well. A premature birth deprives the infant of the nutritional support of the placenta during a time of maximal growth.

The last trimester of gestation is also a time of building nutrient stores. Being born with limited nutrient stores intensifies the already precarious situation for the infant. The physical and metabolic immaturity of preterm infants further compromises their nutrition status. Nutrient absorption, especially of fat and calcium, from an immature GI tract is limited. Consequently, preterm, low-birthweight infants are candidates for nutrient imbalances. Deficiencies of the fat-soluble vitamins, calcium, iron, and zinc are common.

Preterm breast milk is well suited to meet a preterm infant's needs. During early lactation, preterm milk contains higher concentrations of protein and is lower in volume than term milk. The low milk volume is advantageous because preterm infants consume small quantities of milk per feeding, and the higher protein concentration allows for better growth. In many instances, supplements of nutrients specifically designed for preterm infants are added to the mother's expressed breast milk and fed to the infant from a bottle. When fortified with a preterm supplement, preterm breast milk supports growth at a rate that approximates the growth rate that would have occurred within the uterus.

Introducing Cow's Milk

The age at which whole cow's milk should be introduced to the infant's diet has long been a source of controversy. The AAP advises that whole cow's milk is not appropriate during the first year.[28] Children one to two years of age should not be given reduced-fat, low-fat, or fat-free milk routinely; they need the fat of whole milk. Between the ages of two and five years, a gradual transition from whole milk to the lower-fat milks can take place, but care should be taken to avoid excessive restriction of dietary fat.

Dietary Guidelines for Americans 2005

Children two to eight years should consume 2 cups per day of fat-free or low-fat milk or equivalent milk products.

In some infants, particularly those younger than six months of age, whole cow's milk may cause intestinal bleeding, which can lead to iron deficiency. Cow's milk is also a poor source of iron. Consequently, it both causes iron loss and fails to replace iron. Furthermore, the bioavailability of iron from infant cereal and other foods is reduced when cow's milk replaces breast milk or iron-fortified formula during the first year. Compared with breast milk or iron-fortified formula, cow's milk is higher in calcium and lower in vitamin C, characteristics that reduce iron absorption. Furthermore, the higher protein concentration of cow's milk can stress the infant's kidneys. In short, cow's milk is a poor choice during the first year of life; infants need breast milk or iron-fortified infant formula.

Introducing Solid Foods

The high nutrient needs of infancy are met first by breast milk or formula only and then by the limited addition of selected foods over time. Infants gradually develop the ability to chew, swallow, and digest the wide variety of foods available to adults. The caregiver's selection of appropriate foods at the appropriate stages of development is prerequisite to the infant's optimal growth and health.

When to Begin In addition to breast milk or formula, an infant can begin eating solid foods between four and six months.[29] The AAP supports exclusive breastfeeding for six months but recognizes that infants are often developmentally ready to accept complementary foods between four and six months of age.[30] The main purpose of introducing solid foods is to provide needed nutrients that are no longer supplied adequately by breast milk or formula alone. The foods chosen must be those ◆ that the infant is developmentally capable of handling both physically and metabolically. The exact timing depends on the individual infant's needs and developmental readiness (see Table 15-3), which vary from infant to infant because of differences in growth rates, activities, and environmental conditions. ◆ In short, the addition of foods to an infant's diet should be governed by three considerations: the infant's nutrient needs, the infant's physical readiness to handle different forms of foods, and the need to detect and control allergic reactions.

◆ The German word **beikost** (BYE-cost) describes any nonmilk foods given to an infant.

◆ Digestive secretions gradually increase throughout the first year of life, making the digestion of solid foods more efficient.

Food Allergies To prevent allergy and to facilitate its prompt identification should it occur, experts recommend introducing single-ingredient foods, one at a time, in small portions, and waiting four to five days before introducing the next new food.[31] For example, rice cereal is usually the first cereal introduced because it

TABLE 15-3 Infant Development and Recommended Foods

Because each stage of development builds on the previous stage, the foods from an earlier stage continue to be included in all later stages.

Age (mo)	Feeding Skill	Appropriate Foods Added to the Diet
0–4	Turns head toward any object that brushes cheek. Initially swallows using back of tongue; gradually begins to swallow using front of tongue as well. Strong reflex (extrusion) to push food out during first 2 to 3 months.	Feed breast milk or infant formula.
4–6	Extrusion reflex diminishes, and the ability to swallow nonliquid foods develops. Indicates desire for food by opening mouth and leaning forward. Indicates satiety or disinterest by turning away and leaning back. Sits erect with support at 6 months. Begins chewing action. Brings hand to mouth. Grasps objects with palm of hand.	Begin iron-fortified cereal mixed with breast milk, formula, or water. Begin pureed vegetables and fruits.
6–8	Able to self-feed finger foods. Develops pincer (finger to thumb) grasp. Begins to drink from cup.	Begin textured vegetables and fruits. Begin unsweetened, diluted fruit juices from cup.
8–10	Begins to hold own bottle. Reaches for and grabs food and spoon. Sits unsupported.	Begin breads and cereals from table. Begin yogurt. Begin pieces of soft, cooked vegetables and fruit from table. Gradually begin finely cut meats, fish, casseroles, cheese, eggs, and mashed legumes.
10–12	Begins to master spoon, but still spills some.	Add variety. Gradually increase portion sizes.[a]

[a]Portion sizes for infants and young children are smaller than those for an adult. For example, a grain serving might be ½ slice of bread instead of 1 slice, or ¼ cup rice instead of ½ cup.

Foods such as iron-fortified cereals and formulas, mashed legumes, and strained meats provide iron.

is the least allergenic. When it is clear that rice cereal is not causing an allergy, another grain, perhaps barley or oats, is introduced. Wheat cereal is offered last because it is the most common offender. If a cereal causes an allergic reaction such as a skin rash, digestive upset, or respiratory discomfort, it should be discontinued before introducing the next food. A later section in this chapter offers more information about food allergies.

Choice of Infant Foods Infant foods should be selected to provide variety, balance, and moderation. Commercial baby foods offer a wide variety of palatable, nutritious foods in a safe and convenient form. Homemade infant foods can be as nutritious as commercially prepared ones, as long as the cook minimizes nutrient losses during preparation. Ingredients for homemade foods should be fresh, whole foods without added salt, sugar, or seasonings. Pureed food can be frozen in ice cube trays, providing convenient-sized blocks of food that can be thawed, warmed, and fed to the infant. To guard against foodborne illnesses, hands and equipment must be kept clean.

Because recommendations to restrict fat do not apply to children under age two, labels on foods for children under two (such as infant meats and cereals) cannot carry information about fat. Fat information is omitted from infant food labels to prevent parents from restricting fat in infants' diets. Fearing that their infant will become overweight, parents may unintentionally malnourish the infant by limiting fat. In fact, infants and young children, because of their rapid growth, need more fat than older children and adults.

Foods to Provide Iron Rapid growth demands iron. At about four to six months, the infant begins to need more iron than body stores plus breast milk or iron-fortified formula can provide. In addition to breast milk or iron-fortified formula, infants can receive iron from iron-fortified cereals and, once they readily accept solid foods, from meat or meat alternates such as legumes. Iron-fortified cereals contribute a significant amount of iron to an infant's diet, but the iron's bioavailability is poor.[32] Caregivers can enhance iron absorption from iron-fortified cereals by serving vitamin C–rich foods with meals.

Foods to Provide Vitamin C The best sources of vitamin C are fruits and vegetables (see pp. 354–355 in Chapter 10). It has been suggested that infants who are introduced to fruits before vegetables may develop a preference for sweets and find the vegetables less palatable, but there is no evidence to support offering these foods in a particular order.[33]

Fruit juice is a good source of vitamin C, but drinking too much juice can lead to diarrhea in infants and young children.[34] AAP recommendations limit juice consumption for infants and young children (one to six years of age) to between 4 and 6 ounces per day.[35] Beyond these limits, fruit juices contribute excessive kcalories and displace other nutrient-rich foods. Fruit juices should be diluted and served in a cup, not a bottle, once the infant is six months of age or older.

Foods to Omit Concentrated sweets, including baby food "desserts," have no place in an infant's diet. They convey no nutrients to support growth, and the extra food energy can promote obesity. Products containing sugar alcohols such as sorbitol should also be limited, as they may cause diarrhea. Canned vegetables are also inappropriate for infants, as they often contain too much sodium. Honey and corn syrup should never be fed to infants because of the risk of **botulism.*** Infants and young children are vulnerable to foodborne illnesses, and the *Dietary Guidelines 2005* address this risk.

botulism (BOT-chew-lism): an often fatal foodborne illness caused by the ingestion of foods containing a toxin produced by bacteria that grow without oxygen.

* In infants, but not in older individuals, ingestion of *Clostridium botulinum* spores can cause illness when the spores germinate in the intestine and produce a toxin, which is absorbed. Symptoms include poor feeding, constipation, loss of tension in the arteries and muscles, weakness, and respiratory compromise. Infant botulism has been implicated in 5 percent of cases of sudden infant death syndrome (SIDS).

Dietary Guidelines for Americans 2005

Infants and young children should not eat or drink unpasteurized milk, milk products, or juices; raw or undercooked eggs, meat, poultry, fish, or shellfish; or raw sprouts.

Infants and even young children cannot safely chew and swallow any of the foods listed in the margin; ◆ they can easily choke on these foods, a risk not worth taking. Nonfood items may present even greater choking hazards to infants and young children.[36] Parents and caregivers must pay careful attention to eliminate choking hazards in children's environments.

Vegetarian Diets during Infancy The newborn infant is a lactovegetarian. As long as the infant has access to sufficient quantities of either infant formula or breast milk (plus a vitamin D supplement) from a mother who eats an adequate diet, the infant will thrive during the early months. "Health-food beverages," such as rice milk, are inappropriate choices because they lack the protein, vitamins, and minerals infants and toddlers need; in fact, their use can lead to severe nutritional deficiencies.

Infants beyond about six months of age present a greater challenge in terms of meeting nutrient needs by way of vegetarian and, especially, vegan diets. Continued breastfeeding or formula feeding is recommended, but supplementary feedings are necessary to ensure adequate energy and iron intakes. Infants and young children in vegetarian families should be given iron-fortified infant cereals well into the second year. Mashed or pureed legumes, tofu, and cooked eggs can be added to their diets in place of meat.

The risks of malnutrition in infants increase with weaning and reliance on table foods. Infants who receive a well-balanced vegetarian diet that includes milk products and a variety of other foods can easily meet their nutritional requirements for growth. This is not always true for vegan infants; the growth of vegan infants slows significantly around the time of transition from breast milk to solid foods. Protein-energy malnutrition and deficiencies of vitamin D, vitamin B_{12}, iron, and calcium have been reported in infants fed vegan diets. Vegan diets that are high in fiber, other complex carbohydrates, and water will fill infants' stomachs before meeting their energy needs. This problem can be partially alleviated by providing more energy-dense foods, such as nut butters, legumes, dried fruit spreads, and mashed avocado. Using soy formulas (or milk) fortified with calcium, vitamin B_{12}, and vitamin D and including vitamin C–containing foods at meals to enhance iron absorption will help prevent other nutrient deficiencies in vegan diets. Parents or caregivers who choose to feed their infants vegan diets should consult with their pediatrician and a registered dietitian frequently to ensure a nutritionally adequate diet that will support growth.

Foods at One Year At one year of age, whole cow's milk can become a primary source of most of the nutrients an infant needs; 2 to 3 cups a day meets those needs sufficiently. Ingesting more milk than this can displace iron-rich foods, which can lead to **milk anemia.** If powdered milk is used, it should contain fat.

Other foods—meats, iron-fortified cereals, enriched or whole-grain breads, fruits, and vegetables—should be supplied in variety and in amounts sufficient to round out total energy needs. Ideally, a one-year-old will sit at the table, eat many of the same foods everyone else eats, and drink liquids from a cup, not a bottle. Figure 15-6 shows a meal plan that meets a one-year-old's requirements.

© SW Productions/Index Stock Imagery

Ideally, a one-year-old eats many of the same foods as the rest of the family.

◆ To prevent choking, do not give infants or young children:

- Raw carrots
- Cherries
- Gum
- Hard or gel-type candies
- Hot dog slices
- Marshmallows
- Nuts
- Peanut butter
- Popcorn
- Raw celery
- Whole beans
- Whole grapes

Keep these nonfood items out of their reach:

- Coins
- Small balls
- Balloons
- Pen tops

FIGURE 15-6 Sample Meal Plan for a One-Year-Old

SAMPLE MENU

Breakfast	½ c iron-fortified, unsweetened breakfast cereal
	¼ c whole milk (with cereal)
	½ c orange juice
Morning snack	½ c yogurt
	½ c fruit[a]
Lunch	½ sandwich: 1 slice bread with 2 tbs tuna salad or egg salad
	½ c vegetables[b] (steamed carrots)
	½ c whole milk
Afternoon snack	½ slice whole-wheat toast
	1 tbs apple butter
	½ c whole milk
Dinner	1 oz chopped meat or ¼ c well-cooked mashed legumes
	¼ c potato, rice, or pasta
	½ c vegetables[b] (chopped broccoli)
	½ c whole milk

[a]Include citrus fruits, melons, and berries.
[b]Include dark green, leafy and deep yellow vegetables.

Mealtimes with Toddlers

The nurturing of a young child involves more than nutrition. Those who care for young children are responsible not only for providing nutritious milk, foods, and water, but also a safe, loving, secure environment in which the children may grow

milk anemia: iron-deficiency anemia that develops when an excessive milk intake displaces iron-rich foods from the diet.

© Corbis

Toddlers need vitamin A– and vitamin D–fortified whole milk.

and develop. In light of toddlers' developmental and nutrient needs and their often contrary and willful behavior, a few feeding guidelines may be helpful:

- Discourage unacceptable behavior, such as standing at the table or throwing food, by removing the young child from the table to wait until later to eat. Be consistent and firm, not punitive. The child will soon learn to sit and eat.
- Let toddlers explore and enjoy food, even if this means eating with fingers for a while. Learning to use a spoon will come in time.
- Don't force food on children. Rejecting new foods is normal and acceptance is more likely as children become familiar with new foods through repeated opportunities to taste them.
- Provide nutritious foods, and let children choose which ones, and how much, they will eat. Gradually, they will acquire a taste for different foods.
- Limit sweets. Infants and young children have little room for empty-kcalorie foods in their daily energy allowance. Do not use sweets as a reward for eating meals.
- Don't turn the dining table into a battleground. Make mealtimes enjoyable. Teach healthy food choices and eating habits in a pleasant environment.

IN SUMMARY

The primary food for infants during the first 12 months is either breast milk or iron-fortified formula. In addition to nutrients, breast milk also offers immunological protection. At about four to six months, infants should gradually begin eating solid foods. By one year, they are drinking from a cup and eating many of the same foods as the rest of the family.

Nutrition during Childhood

Each year from age one to adolescence, a child typically grows taller by 2 to 3 inches and heavier by 5 to 6 pounds. Growth charts provide valuable clues to a child's health. Weight gains out of proportion to height gains may reflect overeating and inactivity, whereas measures significantly below the standard suggest malnutrition.

Increases in height and weight are only two of the many changes growing children experience (see Figure 15-7). At age one, children can stand alone and are beginning to toddle; by two, they can walk and are learning to run; and by three, they can jump and climb with confidence. Bones and muscles increase in mass and density to make these accomplishments possible. Thereafter, lengthening of the long bones and increases in musculature proceed unevenly and more slowly until adolescence.

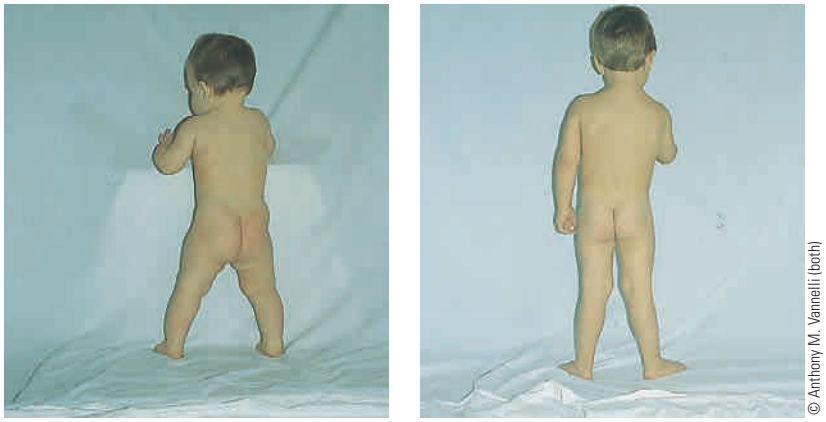
Energy and Nutrient Needs

Children's appetites begin to diminish around one year, consistent with the slowing growth. Thereafter, children spontaneously vary their food intakes to coincide with their growth patterns; they demand more food during periods of rapid growth than during slow growth. Sometimes they seem insatiable, and other times they seem to live on air and water.

Children's energy intakes also vary widely from meal to meal. Even so, their total daily intakes remain remarkably constant.[37] If children eat less at one meal, they typically eat more at the next, and vice versa. Overweight children are exceptions: they do not always adjust their energy intakes appropriately and may eat in response to external cues, disregarding hunger and satiety signals.

Energy Intake and Activity Individual children's energy needs vary widely, depending on their growth and physical activity. A one-year-old child needs about 800 kcalo-

FIGURE 15-7 Body Shape of One-Year-Old and Two-Year-Old Compared



© Anthony M. Vannelli (both)

The body shape of a one-year-old (left) changes dramatically by age two (right). The two-year-old has lost much of the baby fat; the muscles (especially in the back, buttocks, and legs) have firmed and strengthened; and the leg bones have lengthened.

ries a day; an active six-year-old needs twice as many kcalories a day. By age ten, an active child needs about 2000 kcalories a day. Total energy needs increase slightly with age, but energy needs per kilogram of body weight actually decline gradually.

Physically active children of any age need more energy because they expend more, and inactive children can become obese even when they eat less food than the average. Unfortunately, our nation's children are becoming less and less active, with young girls showing a marked reduction in their physical activity. Schools would serve our children well by offering activities to promote physical fitness.[38] Children who learn to enjoy physical play and exercise, both at home and at school, are best prepared to maintain active lifestyles as adults.

Dietary Guidelines for Americans 2005

Children should engage in at least 60 minutes of physical activity on most, preferably all, days of the week.

Some children, notably those adhering to a vegan diet, may have difficulty meeting their energy needs. Grains, vegetables, and fruits provide plenty of fiber, adding bulk, but may provide too few kcalories to support growth. Soy products, other legumes, and nut or seed butters offer more concentrated sources of energy to support optimal growth and development.[39]

Carbohydrate and Fiber Carbohydrate recommendations are based on glucose use by the brain. After one year of age, brain glucose use remains fairly constant and is within the adult range. Carbohydrate recommendations for children from the age of one year on are therefore the same as for adults (see inside front cover).[40]

Fiber recommendations ◆ derive from adult intakes shown to reduce the risk of coronary heart disease and are based on energy intakes. Consequently, fiber recommendations for younger children with low energy intakes are less than those for older ones with high energy intakes.[41]

◆ Fiber recommendations for children:

Age (yr)	AI (g/day)
1–3	19
4–8	25
9–13	
Boys	31
Girls	26
14–18	
Boys	38
Girls	26

Dietary Guidelines for Americans 2005

Children and adolescents should consume whole-grain products often, and at least half of the grains should be whole grains.

Fat and Fatty Acids No RDA for total fat has been established, but the DRI Committee recommends a fat intake of 30 to 40 percent of energy for children 1 to 3 years of age and 25 to 35 percent for children 4 to 18 years of age.[42] As long as children's energy intakes are adequate, fat intakes below 30 percent of total energy do not impair growth.[43] Children who eat low-fat diets, however, tend to have low intakes of some vitamins and minerals. Recommended intakes of the essential fatty acids are based on average intakes (see inside front cover).

Dietary Guidelines for Americans 2005

Keep total fat intake between 30 to 35 percent of kcalories for children 2 to 3 years of age and between 25 and 35 percent of kcalories for children and adolescents 4 to 18 years of age, with most fats coming from sources of polyunsaturated and monounsaturated fatty acids, such as fish, nuts, and vegetable oils.

Protein Like energy needs, total protein needs increase slightly with age, but when the child's body weight is considered, the protein requirement actually declines slightly (see inside front cover). Protein recommendations must consider the requirements for maintaining nitrogen balance, the quality of protein consumed, and the added needs of growth.

Vitamins and Minerals The vitamin and mineral needs of children increase with age (see inside front cover). A balanced diet of nutritious foods can meet children's needs for these nutrients, with the notable exception of iron. Iron-deficiency anemia is a major problem worldwide, as well as being prevalent among U.S. and Canadian children, especially toddlers one to two years of age.[44] During the second year of life, toddlers progress from a diet of iron-rich infant foods such as breast milk, iron-fortified formula, and iron-fortified infant cereal to a diet of adult foods and iron-poor cow's milk. In addition, their appetites often fluctuate—some become finicky about the foods they eat, and others prefer milk and juice to solid foods.[45] All of these situations can interfere with children eating iron-rich foods at a critical time for brain growth and development.

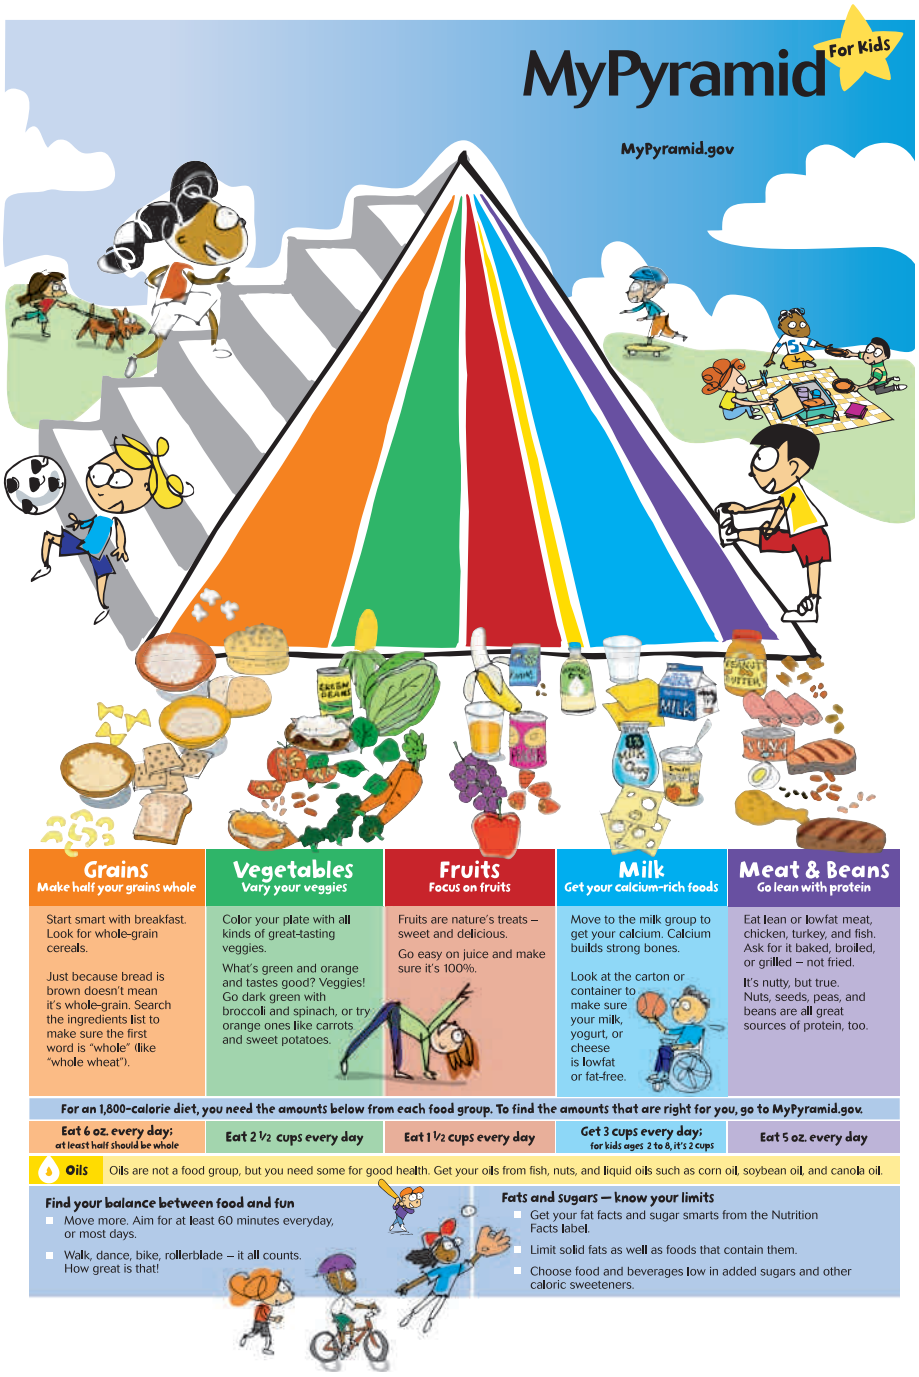
To prevent iron deficiency, children's foods must deliver 7 to 10 milligrams of iron per day. To achieve this goal, snacks and meals should include iron-rich foods, and milk intake should be reasonable so that it will not displace lean meats, fish, poultry, eggs, legumes, and whole-grain or enriched products. (Chapter 13 described iron-rich foods and ways to maximize iron absorption.)

Supplements With the exception of specific recommendations for fluoride, iron, and vitamin D during infancy and childhood, the AAP and other professional groups agree that well-nourished children do not need vitamin and mineral supplements. Despite this, many children and adolescents take supplements.[46] Ironically, children with poor nutrient intakes typically do not receive supplements, and those who do take supplements typically receive extra nutrients they do not need.[47] Furthermore, researchers are still studying the safety of supplement use by children.[48] The Federal Trade Commission has warned parents about giving supplements advertised to prevent or cure childhood illnesses such as colds, ear infections, or asthma. Dietary supplements on the market today include many herbal products that have not been tested for safety and effectiveness in children.

Planning Children's Meals To provide all the needed nutrients, children's meals should include a variety of foods from each food group—in amounts suited to their appetites and needs. Figure 15-8 presents MyPyramid ◆ designed for children 6 to 11 years of age and includes the recommended amounts of food for an 1800-kcalorie intake. Table 15-4 (p. 530) lists amounts of food for several kcalorie levels below 1800 kcalories, which are appropriate for most younger children and sedentary older children. Review Table 2-3 on page 41 for recommended daily amounts of foods from each group for higher kcalorie levels, which are appropriate for active older children.

◆ www.MyPyramid.gov/kids

FIGURE 15-8 Food Guide Pyramid for Young Children



Estimated daily kcalorie needs for active and sedentary children of various ages are shown in Table 15-5 (p. 530).

Children whose diets follow the pattern presented in Figure 15-8 meet their nutrient needs fully, but few children eat according to these recommendations. Based on an analysis of the most recent national food intake data, the USDA found that most (81 percent) children between two and nine years of age have diets that need substantial improvement.[49] A comprehensive survey, called the Feeding Infants and Toddlers Study (FITS), assessed the food and nutrient intakes of more than 3000 infants and toddlers.[50] The survey found that fruit and vegetable intakes of infants and toddlers are limited, and in fact, about 25 percent of infants and toddlers older than 9 months did not eat a single serving of fruits or vegetables in a day.[51] By 15

TABLE 15-4 Recommended Daily Amounts from Each Food Group (1000 to 1600 kCalories)

Food Group	1000 kcal	1200 kcal	1400 kcal	1600 kcal
Fruits	1 c	1 c	1½ c	1½ c
Vegetables	1 c	1½ c	1½ c	2 c
Grains	3 oz	4 oz	5 oz	5 oz
Meat and legumes	2 oz	3 oz	4 oz	5 oz
Milk	2 c	2 c	2 c	3 c
Oils	3 tsp	3 tsp	3 tsp	4 tsp

NOTE: The discretionary kcalorie allowance for these patterns is about 100 kcalories.

TABLE 15-5 Estimated Daily kCalorie Needs for Children

Children	Sedentary[a]	Active[b]
2 to 3 yr	1000	1400
Females		
4 to 8 yr	1200	1800
9 to 13 yr	1600	2200
Males		
4 to 8 yr	1400	2000
9 to 13 yr	1800	2600

[a] *Sedentary* describes a lifestyle that includes only the activities typical of day-to-day life.
[b] *Active* describes a lifestyle that includes at least 60 minutes per day of moderate physical activity (equivalent to walking more than 3 miles per day at 3 to 4 miles per hour) in addition to the activities of day-to-day life.

to 18 months of age, the most commonly consumed vegetable was French fries and the most commonly consumed fruit was bananas—neither particularly rich sources of vitamins or minerals. Parents and caregivers of infants and toddlers thus need to offer a much greater variety of nutrient-dense vegetables and fruits at meals and snacks to help ensure adequate nutrition. Among other nutrition concerns for U.S. children are inadequate intakes of calcium and fiber and excessive intakes of saturated fat.[52]

Hunger and Malnutrition in Children

Most children in the United States and Canada have access to regular meals, but hunger and malnutrition do appear in certain circumstances. Children in very low-income families, for example, are more likely to be hungry and malnourished. An estimated 12 million U.S. children are hungry at least some of the time and are living in poverty.[53] Highlight 16 examines the causes and consequences of hunger in the United States.

When hunger is chronic, children become malnourished and suffer growth retardation. Worldwide, malnutrition takes a devastating toll on children, contributing to nearly half of the deaths of children under four years old. Vitamin A deficiency afflicts 3 to 10 million children worldwide, inducing blindness, stunted growth, and infections.[54] Zinc deficiency also retards growth and typically accompanies protein-energy malnutrition and vitamin A deficiency.

The United Nations Children's Fund, known as UNICEF, helps children living in poverty in developing countries get the nutrition and health care they need. UNICEF works with more than 160 countries through national governments, private-sector partners, and other international agencies to protect children and their rights and to reduce childhood death and illness.

Hunger and Behavior Even when hunger is temporary, as when a child misses one meal, behavior and academic performance are affected. Children who eat nutritious breakfasts improve their school performance and are tardy or absent significantly less often than their peers who do not. A nutritious breakfast is a central feature of a diet that meets the needs of children and supports their healthy growth and development.[55] Children who skip breakfast typically do not make up the deficits at later meals—they simply have lower intakes of energy, vitamins, and minerals than those who eat breakfast. Without breakfast, children perform poorly in tasks requiring concentration, their attention spans are shorter, and they even score lower on intelligence tests than their well-fed peers. Malnourished children are particularly vulnerable. Common sense dictates that it is unreasonable to expect anyone to learn and perform without fuel. For the child who hasn't had breakfast, the morning's lessons may be lost altogether. Even if a child has eaten breakfast, discomfort from hunger may become distracting by late morning. Teachers aware of the late-morning slump in their classrooms wisely request that midmorning snacks be provided; snacks improve classroom performance all the way to lunchtime.

Iron Deficiency and Behavior Iron deficiency has well-known and widespread effects on children's behavior and intellectual performance.[56] In addition to carrying oxygen in the blood, iron transports oxygen within cells, which use it for energy metabolism. Iron is also used to make neurotransmitters—most notably, those that regulate the ability to pay attention, which is crucial to learning. Consequently, iron deficiency not only causes an energy crisis, but also directly impairs attention span and learning ability.

Iron deficiency is often diagnosed by a quick, easy, inexpensive hemoglobin or hematocrit test that detects a deficit of iron in the *blood.* A child's *brain,* however, is sensitive to low iron concentrations long before the blood effects appear. Iron deficiency lowers the "motivation to persist in intellectually challenging tasks" and impairs overall intellectual performance. Anemic children perform poorly on tests and are disruptive in the classroom; iron supplementation improves learning and memory. When combined with other nutrient deficiencies, iron-deficiency anemia has synergistic effects that are especially detrimental to learning. Furthermore, children who had iron-deficiency anemia *as infants* continue to perform poorly as they grow older, even if their iron status improves.[57] The long-term damaging effects on mental development make prevention and treatment of iron deficiency during infancy and early childhood a high priority.

© George Doyle/Getty Images

Healthy, well-nourished children are alert in the classroom and energetic at play.

Other Nutrient Deficiencies and Behavior A child with any of several nutrient deficiencies may be irritable, aggressive, and disagreeable, or sad and withdrawn. Such a child may be labeled "hyperactive," "depressed," or "unlikable," when in fact these traits may be due to simple, even marginal, malnutrition. Parents and medical practitioners often overlook the possibility that malnutrition may account for abnormalities of appearance and behavior. Any departure from normal healthy appearance and behavior is a sign of possible poor nutrition (see Table 15-6). In any such case, inspection of the child's diet by a registered dietitian or other qualified health care professional is in order. Any suspicion of dietary inadequacies, no matter what other causes may be implicated, should prompt steps to correct those inadequacies immediately.

TABLE 15-6 Physical Signs of Malnutrition in Children

	Well-Nourished	Malnourished	Possible Nutrient Deficiencies
Hair	Shiny, firm in the scalp	Dull, brittle, dry, loose; falls out	PEM
Eyes	Bright, clear pink membranes; adjust easily to light	Pale membranes; spots; redness; adjust slowly to darkness	Vitamin A, the B vitamins, zinc, and iron
Teeth and gums	No pain or caries, gums firm, teeth bright	Missing, discolored, decayed teeth; gums bleed easily and are swollen and spongy	Minerals and vitamin C
Face	Clear complexion without dryness or scaliness	Off-color, scaly, flaky, cracked skin	PEM, vitamin A, and iron
Glands	No lumps	Swollen at front of neck, cheeks	PEM and iodine
Tongue	Red, bumpy, rough	Sore, smooth, purplish, swollen	B vitamins
Skin	Smooth, firm, good color	Dry, rough, spotty; "sandpaper" feel or sores; lack of fat under skin	PEM, essential fatty acids, vitamin A, B vitamins, and vitamin C
Nails	Firm, pink	Spoon-shaped, brittle, ridged	Iron
Internal systems	Regular heart rhythm, heart rate, and blood pressure; no impairment of digestive function, reflexes, or mental status	Abnormal heart rate, heart rhythm, or blood pressure; enlarged liver, spleen; abnormal digestion; burning, tingling of hands, feet; loss of balance, coordination; mental confusion, irritability, fatigue	PEM and minerals
Muscles and bones	Muscle tone; posture, long bone development appropriate for age	"Wasted" appearance of muscles; swollen bumps on skull or ends of bones; small bumps on ribs; bowed legs or knock-knees	PEM, minerals, and vitamin D

Old, lead-based paint threatens the health of an exploring child.

The Malnutrition-Lead Connection

Children who are malnourished are vulnerable to lead poisoning. They absorb more lead if their stomachs are empty; if they have low intakes of calcium, zinc, vitamin C, or vitamin D; and, of greatest concern because it is so common, if they have iron deficiencies. Iron deficiency weakens the body's defenses against lead absorption, and lead poisoning can cause iron deficiency. Common to both iron deficiency and lead poisoning are a low socioeconomic background and a lack of immunizations against infectious diseases. Another common factor is pica—a craving for nonfood items. Many children with lead poisoning eat dirt or chips of old paint, two common sources of lead.

The anemia brought on by lead poisoning may be mistaken for a simple iron deficiency and therefore may be incorrectly treated. Like iron deficiency, mild lead toxicity has nonspecific symptoms, including diarrhea, irritability, and fatigue. Adding iron to the diet does not reverse the symptoms; exposure to lead must stop and treatment for lead poisoning must begin. With further exposure, the symptoms become more pronounced, and children develop learning disabilities and behavioral problems. Still more severe lead toxicity can cause irreversible nerve damage, paralysis, mental retardation, and death.

More than 300,000 children in the United States—most of them under age six—have blood lead concentrations high enough to cause mental, behavioral, and other health problems.[58] Lead toxicity in young children comes from their own behaviors and activities—putting their hands in their mouths, playing in dirt and dust, and chewing on nonfood items.[59] Unfortunately, the body readily absorbs lead during times of rapid growth and hoards it possessively thereafter. Lead is not easily excreted and accumulates mainly in the bones, but also in the brain, teeth, and kidneys. Tragically, a child's neuromuscular system is also maturing during these first few years of life. No wonder children with elevated lead levels experience impairment of balance, motor development, and the relaying of nerve messages to and from the brain. Deficits in intellectual development are only partially reversed when lead levels decline.[60]

Federal laws mandating reductions in leaded gasolines, lead-based solder, and other products over the past four decades have helped to reduce the amounts of lead in food and in the environment in the United States. As a consequence, the prevalence of lead toxicity in children has declined dramatically for most of the United States, but lead exposure is still a threat in certain communities.[61] The accompanying "How to" presents strategies for defending children against lead toxicity.

Hyperactivity and "Hyper" Behavior

All children are naturally active, and many of them become overly active on occasion—for example, in anticipation of a birthday party. Such behavior is markedly different from true **hyperactivity.**

Hyperactivity Hyperactive children have trouble sleeping, cannot sit still for more than a few minutes at a time, act impulsively, and have difficulty paying attention. These behaviors interfere with social development and academic progress. The cause of hyperactivity remains unknown, but it affects about 5 to 10 percent of young school-age children.[62] To resolve the problems surrounding hyperactivity, physicians often recommend specific behavioral strategies, special educational programs, and psychological counseling. In many cases, they prescribe medication.[63]

Parents of hyperactive children sometimes seek help from alternative therapies, including special diets. They mistakenly believe a solution may lie in manipulating the diet—most commonly, by excluding sugar or food additives. Adding carrots or eliminating candy is such a simple solution that many parents eagerly give such dietary advice a try. However, these dietary changes will not solve the problem, and studies have consistently found no convincing evidence that sugar causes hyperactivity or worsens behavior.

hyperactivity: inattentive and impulsive behavior that is more frequent and severe than is typical of others a similar age; professionally called **attention-deficit/hyperactivity disorder (ADHD).**

HOW TO Protect against Lead Toxicity

Researchers simultaneously made three major discoveries about lead toxicity: lead poisoning has *subtle* effects, the effects are *permanent,* and they occur at *low levels of exposure.* The amount of lead recognized to cause harm is only 10 micrograms per 100 milliliters of blood. Some research shows that blood lead concentrations *below* this amount may adversely affect children's scores on intelligence tests.[a] Consequently, consumers should take ultraconservative measures to protect themselves, and especially their infants and young children, from lead poisoning. The American Academy of Pediatrics and the Centers for Disease Control recommend screening in communities with a substantial number of houses built before 1950 and in those with a substantial number of children with elevated lead levels. In addition to screening children most likely to be exposed, pediatricians should alert all parents to the possible dangers of lead exposure and explain prevention strategies.

Preventive strategies include:

- In contaminated environments, keep small children from putting dirty or old painted objects in their mouths, and make sure children wash their hands before eating. Similarly, keep small children from eating any nonfood items. Lead poisoning has been reported in young children who have eaten crayons or pool cue chalk.
- Wet-mop floors and damp-sponge walls regularly. Children's blood lead levels decline when the homes they live in are cleaned regularly.
- Be aware that other countries do not have the same regulations protecting consumers against lead. Children have been poisoned by eating crayons made in China and drinking fruit juice canned in Mexico.
- Do not use lead-contaminated water to make infant formula.
- Once you have opened canned food, store it in a lead-free container to prevent lead migration into the food.
- Do not store acidic foods or beverages (such as vinegar or orange juice) in ceramic dishware or alcoholic beverages in pewter or crystal decanters.
- Many manufacturers are now making lead-safe products. Old, handmade, or imported ceramic cups and bowls may contain lead and should not be used to heat coffee or tea or acidic foods such as tomato soup.
- U.S. wineries have stopped using lead in their foil seals, but older bottles may still be around, and other countries may still use lead. To be safe, wipe the foil-sealed rim of a wine bottle with a clean wet cloth before removing the cork.
- Feed children nutritious meals regularly.
- Before using your newspaper to wrap food, mulch garden plants, or add to your compost, confirm with the publisher that the paper uses no lead in its ink.

The Environmental Protection Agency (EPA) also publishes a booklet, *Lead and Your Drinking Water,* in which the following cautions appear:

- Have the water in your home tested by a competent laboratory.
- Use only cold water for drinking, cooking, and making formula (cold water absorbs less lead).
- When water has been standing in pipes for more than two hours, flush the cold-water pipes by running water through them for 30 seconds before using it for drinking, cooking, or mixing formulas.
- If lead contamination of your water supply seems probable, obtain additional information and advice from the EPA and your local public health agency.

By taking these steps, parents can protect themselves and their children from this preventable danger.[b]

[b] Call the National Lead Information Center hotline at (800) 424-LEAD (424-5323) for general information.

Misbehaving Even a child who is not truly hyperactive can be difficult to manage at times. Michael may act unruly out of a desire for attention, Jessica may be cranky because of a lack of sleep, Christopher may react violently after watching too much television, and Sheila may be unable to sit still in class due to a lack of exercise. All of these children may benefit from more consistent care—regular hours of sleep, regular mealtimes, and regular outdoor activity.

Food Allergy and Intolerance

Food allergy is frequently blamed for physical and behavioral abnormalities in children, but just 6 percent of children are diagnosed with true food allergies.[64] Food allergies diminish with age, until in adulthood they affect only about 1 or 2 percent of the population.[65]

A true food allergy occurs when fractions of a food protein or other large molecule are absorbed into the blood and elicit an immunologic response. (Recall that proteins are normally dismantled in the digestive tract to amino acids that are absorbed without such a reaction.) The body's immune system reacts to these large food molecules as it does to other antigens—by producing antibodies, histamines, or other defensive agents.

Detecting Food Allergy Allergies may have one or two components. They always involve antibodies, but they may or may not involve symptoms. ◆ This means

◆ A person who produces antibodies *without* having any symptoms has an **asymptomatic allergy;** a person who produces antibodies *and* has symptoms has a **symptomatic allergy.**

food allergy: an adverse reaction to food that involves an immune response; also called **food-hypersensitivity reaction.**

© Polara Studios, Inc.

These normally wholesome foods may cause life-threatening symptoms in people with allergies.

that allergies can be diagnosed only by testing for antibodies. Even symptoms exactly like those of an allergy may not be caused by an allergy. However, once a food allergy has been diagnosed, the required treatment is strict elimination of the offending food. Children with allergies, like all children, need all their nutrients, so it is important to include other foods that offer the same nutrients as the omitted foods.[66]

Allergic reactions to food may be immediate or delayed. In either case, the antigen interacts immediately with the immune system, but the timing of symptoms varies from minutes to 24 hours after consumption of the antigen. Identifying the food that causes an immediate allergic reaction is fairly easy because the symptoms appear shortly after the food is eaten. Identifying the food that causes a delayed reaction is more difficult because the symptoms may not appear until much later. By this time, many other foods may have been eaten, complicating the picture.

Anaphylactic Shock The life-threatening food allergy reaction of **anaphylactic shock** is most often caused by peanuts, tree nuts, milk, eggs, wheat, soybeans, fish, or shellfish. Among these foods, eggs, milk, soy, and peanuts most often cause problems in children. Children are more likely to outgrow allergies to eggs, milk, and soy than allergies to peanuts. Peanuts cause more life-threatening reactions than do all other food allergies combined. Research is currently under way to help people with peanut allergies tolerate small doses, thus saving lives and minimizing reactions.[67] One possible solution depends on finding a natural, hypoallergenic peanut among the 14,000 varieties of peanuts. Families of children with a life-threatening food allergy and school personnel who supervise them must guard them against any exposure to the allergen. The child must learn to identify which foods pose a problem and then learn and use refusal skills for all foods that may contain the allergen.

Parents of children with allergies can pack safe foods for lunches and snacks and ask school officials to strictly enforce a "no swapping" policy in the lunchroom. The child must be able to recognize the symptoms of impending anaphylactic shock, ◆ such as a tingling of the tongue, throat, or skin, or difficulty breathing. Any person with food allergies severe enough to cause anaphylactic shock should wear a medical alert bracelet or necklace. Finally, the responsible child and the school staff should be prepared with injections of epinephrine, ◆ which prevents anaphylaxis after exposure to the allergen. Many preventable deaths occur each year when people with food allergies accidentally ingest the allergen but have no epinephrine available.

◆ Symptoms of impending anaphylactic shock:
- Tingling sensation in mouth
- Swelling of the tongue and throat
- Irritated, reddened eyes
- Difficulty breathing, asthma
- Hives, swelling, rashes
- Vomiting, abdominal cramps, diarrhea
- Drop in blood pressure
- Loss of consciousness
- Death

◆ Reminder: *Epinephrine* is a hormone of the adrenal gland that modulates the stress response; formerly called **adrenaline.** When administered by injection, epinephrine counteracts anaphylactic shock by opening the airways and maintaining heartbeat and blood pressure.

Food Labeling As of 2006, food labels must list the presence of common allergens in plain language, using the names of the eight most common allergy-causing foods.[68] For example, a food containing "textured vegetable protein" must say "soy" on its label. Similarly, "casein" must be identified as "milk," and so forth. Food producers must also prevent cross-contamination during production and clearly label foods in which it is likely to occur.[69] For example, equipment used for making peanut butter must be scrupulously clean before being used to pulverize cashew nuts for cashew butter to protect unsuspecting cashew butter consumers from peanut allergens.

Technology may soon offer new solutions. New drugs are being developed that may interfere with the immune response that causes allergic reactions.[70] Also, through genetic engineering, scientists may one day create allergen-free peanuts, soybeans, and other foods to make them safer.

Food Intolerances Not all **adverse reactions** to foods are food allergies, although even physicians may describe them as such. Signs of adverse reactions to foods include stomachaches, headaches, rapid pulse rate, nausea, wheezing, hives, bronchial irritation, coughs, and other such discomforts. Among the causes may be reactions to chemicals in foods, such as the flavor enhancer monosodium glutamate (MSG), the natural laxative in prunes, or the mineral sulfur; digestive diseases, such as obstructions or injuries; enzyme deficiencies, such as lactose intolerance; and even psychological aversions. These reactions involve symptoms but no antibody production. Therefore, they are **food intolerances,** not allergies.

anaphylactic (ana-fill-LAC-tic) **shock:** a life-threatening, whole-body allergic reaction to an offending substance.

adverse reactions: unusual responses to food (including intolerances and allergies).

food intolerances: adverse reactions to foods that do not involve the immune system.

Pesticides on produce may also cause adverse reactions. Pesticides that were applied in the fields may linger on the foods. Health risks from pesticide exposure may be low for healthy adults, but children are vulnerable. Therefore, government agencies have set a **tolerance level** for each pesticide by first identifying foods that children commonly eat in large amounts and then considering the effects of pesticide exposure during each developmental stage.

Hunger, lead poisoning, hyperactivity, and allergic reactions can all adversely affect a child's nutrition status and health. Fortunately, each of these problems has solutions. They may not be easy solutions, but at least we have a reasonably good understanding of the problems and ways to correct them. Such is not the case with the most pervasive health problem for children in the United States—obesity.

Childhood Obesity

The number of overweight children has increased dramatically over the past three decades (see Figure 15-9). Like their parents, children in the United States are becoming fatter. An estimated 17 percent of U.S. children and adolescents 2 to 19 years of age are overweight.[71] Based on data from the BMI-for-age growth charts, children and adolescents are categorized as *at risk of overweight* above the 85th percentile and as *overweight* at the 95th percentile and above. Prevalence data reflect only children and adolescents in the overweight category. If those at risk of overweight were also included, the estimated 17 percent would likely double. Figure 15-10 (p. 536) presents the BMI for children and adolescents, indicating cutoff points for overweight and at risk of overweight.

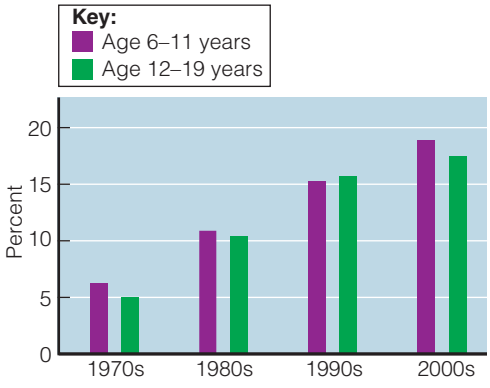
The use of the term *overweight* instead of *obese* when referring to children with a BMI above the age- and gender-specific 95th percentiles is controversial. Some experts think it is best not to label children as obese, whereas others think it important to recognize the full extent of the problem. The Institute of Medicine's Committee on Prevention of Obesity in Children and Youth acknowledges the use of the term *overweight* to describe obese children but asserts that *obese* conveys the seriousness, urgency, medical nature, and need for immediate action more effectively than the term *overweight* does.[72]

The problem of obesity in children is especially troubling because overweight children have the potential of becoming obese adults with all the social, economic, and medical ramifications that often accompany obesity. They have additional problems, too, arising from differences in their growth, physical health, and psychological development. In trying to explain the rise in childhood obesity, researchers point to both genetic and environmental factors.

Genetic and Environmental Factors Parental obesity predicts an early increase in a young child's BMI, and it more than doubles the chances that a young child will become an obese adult. Children with neither parent obese have a less than 10 percent chance of becoming obese in adulthood, whereas overweight teens with at least one obese parent have a greater than 80 percent chance of being obese adults. Also, as children grow older, their body weight becomes an important factor in determining their obesity as adults.[73] The link between parental and child obesity reflects both genetic and environmental factors (as described in Chapter 9).

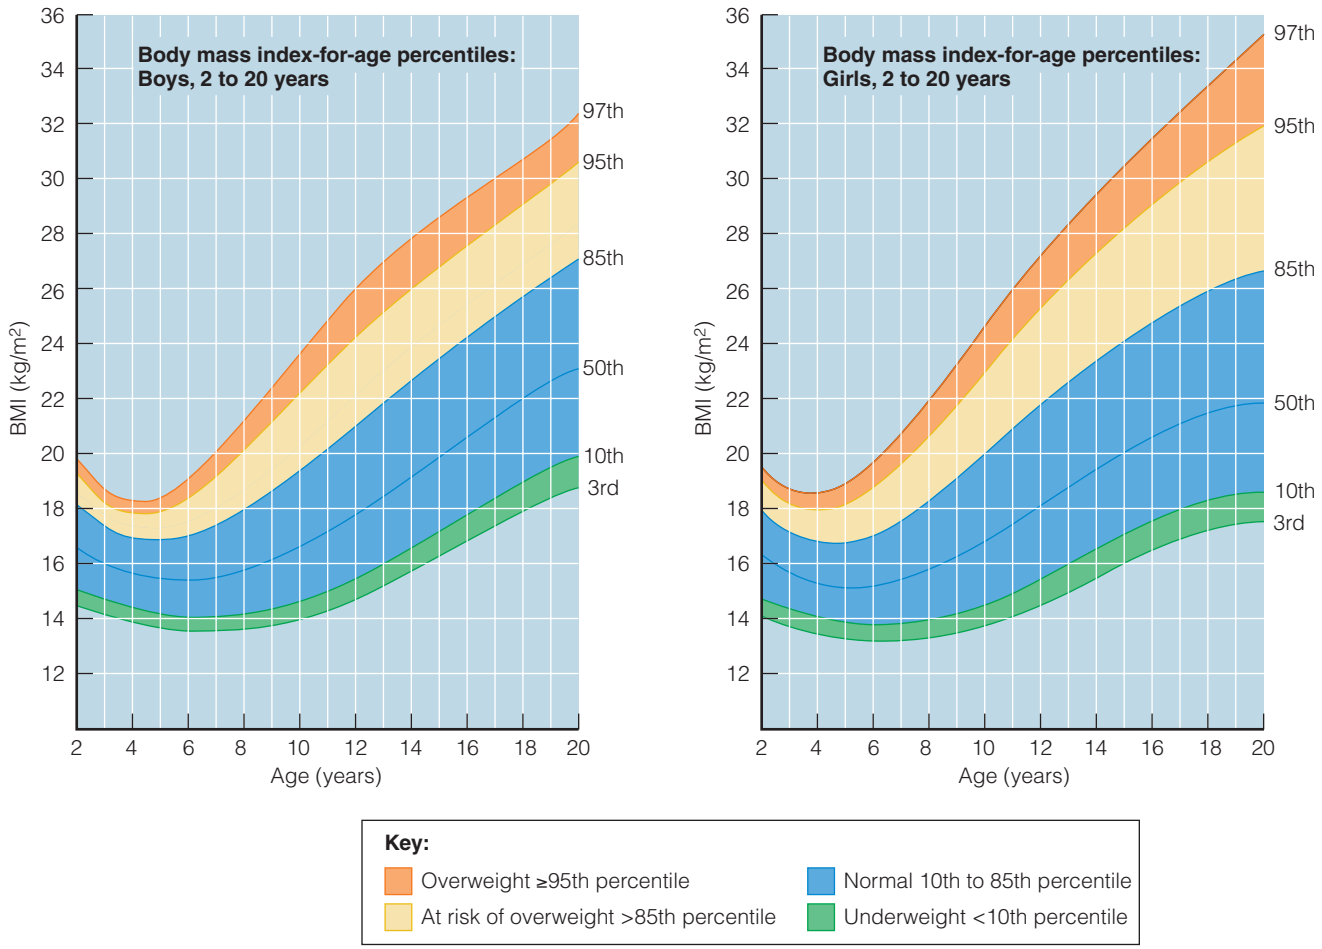
Diet and physical inactivity must also play a role in explaining why children are heavier today than they were 30 or so years ago. As the prevalence of childhood obesity throughout the United States has more than doubled for young children and adolescents, and tripled for children 6 to 11 years of age, the society our children live in has changed considerably.[74] In many families today, both parents work outside the home and work longer hours; more emphasis is placed on convenience foods and foods eaten away from home; meal choices at school are more diverse and often less nutritious; sedentary activities such as watching television and playing video or computer games occupy much of children's free time; and opportunities for

FIGURE 15-9 Trends in Childhood Obesity



tolerance level: the maximum amount of residue permitted in a food when a pesticide is used according to the label directions.

FIGURE 15-10 Body Mass Index-for-Age Percentiles: Boys and Girls, Age 2 to 20



physical activity and outdoor play both during and after school have declined.[75] All of these factors—and many others—influence children's eating and activity patterns.

Children learn food behaviors from their families, and research confirms the significant roles parents play in teaching their children about healthy food choices, providing nutrient-dense foods, and serving as role models.[76] When parents eat fruits and vegetables frequently, their children do, too.[77] The more fruits and vegetables children eat, the more vitamins, minerals, and fibers, and the less saturated fat in their diets.

Research shows that one in four toddlers (19 to 24 months of age) exceeds estimated energy requirements as a result of eating such foods as candy, pizza, chicken nuggets, soda, sweet tea, and salty snacks like cheese puffs and chips.[78] Thus, when researchers ask, "Are today's children eating more kcalories than those of 30 years ago?" the answer is, "Yes." Some researchers report an increase of 100 to 200 kcalories a day for all age groups, enough to account for significant weight gains.[79]

Coincidentally or not, as the prevalence of obesity among both children and adults has surged over the past three decades, so has the consumption of added sugars and, especially, high-fructose corn syrup—the easily consumed, energy-dense liquid sugar added to soft drinks. Each 12-ounce can of soft drink provides the equivalent of about 10 teaspoons of sugar and 150 kcalories. More than half of children in school consume at least one soft drink each day at school; adolescent males consume the most—four or more cans daily.[80] According to one estimate, the risk of obesity increases by 60 percent with each sugared soft drink consumed daily.[81]

No doubt, the tremendous increase in soft drink consumption plays a role, but much of the obesity epidemic can be explained by lack of physical activity. Children have become more sedentary, and sedentary children are more often overweight.[82] Television watching ◆ may contribute most to physical inactivity. A child who spends more than an hour or two each day in front of a television, computer monitor, or other media can become overweight and develop unhealthy blood lipids even while eating fewer kcalories than a more active child.[83]

◆ TV fosters obesity because it:
- Requires no energy beyond basal metabolism
- Replaces vigorous activities
- Encourages snacking
- Promotes a sedentary lifestyle

Playing video games influences children's activity patterns similarly.

Children who have television sets in their bedrooms spend more time watching TV and are more likely to be overweight than children who do not have televisions in their rooms.[84] Children who watch a great deal of television are most likely to be overweight and least likely to eat family meals or fruits and vegetables.[85] They often snack on the nutrient-poor, energy-dense foods that are advertised.[86] The average child sees an estimated 30,000 TV commercials a year—many peddling foods high in sugar, saturated fat, and salt such as sugar-coated breakfast cereals, candy bars, chips, fast foods, and carbonated beverages. More than half of all food advertisements are aimed specifically at children and market their products as fun and exciting.[87] Not surprisingly, the more time children spend watching television, the more they request these advertised foods and beverages—and they get their requests about half of the time.[88] The most popular foods and beverages are marketed to children and adolescents on the Internet as well, using "advergaming" (advertised product as part of a game), cartoon characters or "spokes-characters," and designated children's areas.[89]

The physically inactive time spent watching television is second only to time spent sleeping. Children also spend more time playing video games. These activities use no more energy than resting, displace participation in more vigorous activities, and foster snacking on high-fat foods.[90] Simply reducing the amount of time spent watching television (and playing video games) can improve a child's BMI. The American Academy of Pediatrics (AAP) now recommends limiting television and video time to two hours per day as a strategy to help prevent childhood obesity.[91]

Growth Overweight children develop a characteristic set of physical traits. They typically begin puberty earlier and so grow taller than their peers at first, but then they stop growing at a shorter height. They develop greater bone and muscle mass in response to the demand of having to carry more weight—both fat and lean weight. Consequently, they appear "stocky" even when they lose their excess fat.

Physical Health Like overweight adults, overweight children display a blood lipid profile indicating that atherosclerosis is beginning to develop—high levels of total cholesterol, triglycerides, and LDL cholesterol. Overweight children also tend to have high blood pressure; in fact, obesity is a leading cause of pediatric hypertension.[92] Their risks for developing type 2 diabetes and respiratory diseases (such as asthma) are also exceptionally high.[93] These relationships between childhood obesity and chronic diseases are discussed fully in Highlight 15.

Psychological Development In addition to the physical consequences, childhood obesity brings a host of emotional and social problems.[94] Because people frequently judge others on appearance more than on character, overweight children are often victims of prejudice. Many suffer discrimination by adults and rejection by their peers. They may have poor self-images, a sense of failure, and a passive approach to life. Television shows, which are a major influence in children's lives, often portray the fat person as the bumbling misfit. Overweight children may come to accept this negative stereotype in themselves and in others, which can lead to additional emotional and social problems. Researchers investigating children's reactions to various body types find that both normal-weight and underweight children respond unfavorably to overweight bodies.

Prevention and Treatment of Obesity Medical science has worked wonders in preventing or curing many of even the most serious childhood diseases, but obesity remains a challenge.[95] Once excess fat has been stored, it is challenging to lose. In light of all this, parents are encouraged to make major efforts to prevent childhood

Television watching influences children's eating habits and activity patterns.

obesity or to begin treatment early—before adolescence.[96] Treatment must consider the many aspects of the problem and possible solutions. The most successful approach integrates diet, physical activity, psychological support, and behavioral changes.[97]

Diet The initial goal for overweight children is to reduce the rate of weight gain; that is, to maintain weight while the child grows taller. Continued growth will then accomplish the desired change in weight for height. Weight loss is usually not recommended because diet restriction can interfere with growth and development. Intervention for some older, overweight children with accompanying medical conditions may warrant weight loss, but this treatment requires an individualized approach based on the degree of overweight and severity of the medical conditions.[98] Whether the goal is to treat or prevent obesity, the following strategies may be helpful:

- Serve family meals that reflect kcalorie control both in the foods offered and in the ways foods are prepared.
- Involve children in shopping for food and preparing meals.
- Encourage children to eat only when they are hungry, to eat slowly, to pause and enjoy their table companions, and to stop eating when they are full.
- Teach them how to select nutrient-dense foods (low-fat and non-fat milk and milk products for children 3 years of age and older, fruits and vegetables, whole grains, legumes, fish, and lean meat) that will meet their nutrient needs within their energy allowances. Also, teach them to serve themselves appropriate portions at meals; the amount of food offered influences the amount of food eaten.[99]
- Limit foods high in saturated and *trans* fats (see Table H5-1 in Highlight 5) and high-sugar foods, including sugar-sweetened soft drinks.
- Never force children to clean their plates.
- Plan for snack times and provide a variety of nutritious snacks (see Table 15-8 later in this chapter).
- Discourage eating while watching TV.

Dietary Guidelines for Americans 2005

Help overweight children reduce the rate of body weight gain while allowing growth and development. Consult a health care provider before placing a child on a weight-reduction diet.

Physical Activity The many benefits of physical activity are well known but often are not enough to motivate overweight people, especially children. Yet regular vigorous activity can improve a child's weight, body composition, and physical fitness.[100] Ideally, parents will limit sedentary activities and encourage daily physical activity to promote strong skeletal, muscular, and cardiovascular development and instill in their children the desire to be physically active throughout life. Most importantly, parents need to set a good example. Physical activity is a natural and lifelong behavior of healthy living. It can be as simple as riding a bike, playing tag, jumping rope, or doing chores. It need not be an organized sport; it just needs to be some activity on a regular basis. The AAP supports the efforts of schools to include more physical activity in the curriculum and encourages parents to support their children's participation.[101]

Psychological Support Weight-loss programs that involve parents and other caregivers in treatment report greater success than those without parental involvement. Because obesity in parents and their children tends to be positively correlated, both benefit when parents participate in a weight-loss program. Parental attitudes about food greatly influence children's eating behavior, so it is important that the influence be positive. Otherwise, eating problems may become exacerbated.

Behavioral Changes In contrast to traditional weight-loss programs that focus on *what* to eat, behavioral programs focus on *how* to eat. These techniques involve changing learned habits that lead a child to eat excessively.

Obesity is prevalent in our society. Because treatment of obesity is frequently unsuccessful, it is most important to prevent its onset. Above all, be sensible in teaching children how to maintain appropriate body weight. Children can easily get the impression that their worth is tied to their body weight. Parents and the media are most influential in shaping self-concept, weight concerns, and dieting practices.[102] Some parents fail to realize that society's ideal of slimness can be perilously close to starvation and that a child encouraged to "diet" cannot obtain the energy and nutrients required for normal growth and development. Even healthy children without diagnosable eating disorders have been observed to limit their growth through "dieting." Weight gain in truly overweight children can be managed without compromising growth, but it should be overseen by a health care professional.

Eating is more fun for children when friends are there.

Mealtimes at Home

Traditionally, parents served as **gatekeepers,** determining what foods and activities were available in their children's lives. Then the children made their own selections. Gatekeepers who wanted to promote nutritious choices and healthful habits provided access to nutrient-dense, delicious foods and opportunities for active play at home.

In today's consumer-oriented society, children have greater influence over family decisions concerning food—the fast-food restaurant the family chooses when eating out, the type of food the family eats at home, and the specific brands the family purchases at the grocery store. Parental guidance in food choices is still necessary, but teaching children consumer skills to help them make informed choices is equally important.

Honoring Children's Preferences Researchers attempting to explain children's food preferences encounter contradictions. Children say they like colorful foods, yet they most often reject green and yellow vegetables in favor of brown peanut butter and white potatoes, apple wedges, and bread. They seem to like raw vegetables better than cooked ones, so it is wise to offer vegetables that are raw or slightly undercooked, served separately, and easy to eat. Foods should be warm, not hot, because a child's mouth is much more sensitive than an adult's. The flavor should be mild because a child has more taste buds, and smooth foods such as mashed potatoes or split-pea soup should contain no lumps (a child wonders, with some disgust, what the lumps might be). Children prefer foods that are familiar, so offer various foods regularly.

Make mealtimes fun for children. Young children like to eat at little tables and to be served small portions of food. They like sandwiches cut in different geometric shapes and common foods called silly names. They also like to eat with other children, and they tend to eat more when in the company of their friends. Children are also more likely to give up their prejudices against foods when they see their peers eating them.

Learning through Participation Allowing children to help plan and prepare the family's meals provides enjoyable learning experiences and encourages children to eat the foods they have prepared. Vegetables are pretty, especially when fresh, and provide opportunities for children to learn about color, seeds, growing vegetables, and shapes and textures—all of which are fascinating to young children. Measuring, stirring, washing, and arranging foods are skills that even a young child can practice with enjoyment and pride (see Table 15-7).

Avoiding Power Struggles Problems over food often arise during the second or third year, when children begin asserting their independence. Many of these problems stem from the conflict between children's developmental stages and capabilities and parents who, in attempting to do what they think is best for their children,

TABLE 15-7 Food Skills of Preschool Children[a]

Age 1 to 2 years, when large muscles develop:

- Uses short-shanked spoon
- Helps feed self
- Lifts and drinks from cup
- Helps scrub, tear, break, or dip foods

Age 3 years, when medium hand muscles develop:

- Spears food with fork
- Feeds self independently
- Helps wrap, pour, mix, shake, or spread foods
- Helps crack nuts with supervision

Age 4 years, when small finger muscles develop:

- Uses all utensils and napkin
- Helps roll, juice, mash, or peel foods
- Cracks egg shells

Age 5 years, when fine coordination of fingers and hands develops:

- Helps measure, grind, grate, and cut (soft foods with dull knife)
- Uses hand mixer with supervision

[a]These ages are approximate. Healthy, normal children develop at their own pace.

gatekeepers: with respect to nutrition, key people who control other people's access to foods and thereby exert profound impacts on their nutrition. Examples are the spouse who buys and cooks the food, the parent who feeds the children, and the caregiver in a day-care center.

© Masterfile

Children enjoy eating the foods they help to prepare.

try to control every aspect of eating. Such conflicts can disrupt children's abilities to regulate their own food intakes or to determine their own likes and dislikes. For example, many people share the misconception that children must be persuaded or coerced to try new foods. In fact, the opposite is true. When children are forced to try new foods, even by way of rewards, they are less likely to try those foods again than are children who are left to decide for themselves. Similarly, when children are restricted from eating their favorite foods, they are more likely to want those foods.[103] Wise parents provide healthful foods and allow their child to determine *how much* and even *whether* to eat.

When introducing new foods, offer them one at a time and only in small amounts such as one bite at first. The more often a food is presented to a young child, the more likely the child will accept that food. Offer the new food at the beginning of the meal, when the child is hungry, and allow the child to make the decision to accept or reject it. Never make an issue of food acceptance.

Choking Prevention Parents must always be alert to the dangers of choking. A choking child is silent, so an adult should be present whenever a child is eating. Make sure the child sits when eating; choking is more likely when a child is running or falling. (See p. 525 for a list of foods and nonfood items most likely to cause choking.)

Playing First Children may be more relaxed and attentive at mealtime if outdoor play or other fun activities are scheduled before, rather than immediately after, mealtime. Otherwise children "hurry up and eat" so that they can go play.

Snacking Parents may find that when their children snack, they aren't hungry at mealtimes. Instead of teaching children *not* to snack, parents are wise to teach them *how* to snack. Provide snacks that are as nutritious as the foods served at mealtime. Snacks can even be mealtime foods served individually over time, instead of all at once on one plate. When providing snacks to children, think of the five food groups and offer such snacks as pieces of cheese, tangerine slices, and egg salad on whole-wheat crackers (see Table 15-8). Snacks that are easy to prepare should be readily available to children, especially if they arrive home from school before their parents.

To ensure that children have healthy appetites and plenty of room for nutritious foods when they are hungry, parents and teachers must limit access to candy, soft drinks, and other concentrated sweets. Limiting access includes limiting the amount of pocket money children have to buy such foods themselves.[104] If these foods are permitted in large quantities, the only possible outcomes are nutrient deficiencies, obesity, or both. The preference for sweets is innate; most children do not naturally select nutritious foods on the basis of taste. When children are allowed to create meals freely from a variety of foods, they typically select foods that provide a lot of sugar. When their parents are watching, or even when they only think their parents are watching, children improve their selections.

Sweets need not be banned altogether. Children who are exceptionally active can enjoy high-kcalorie foods such as ice cream or pudding from the milk group or pancakes from the bread group. Sedentary children need to become more active so they can also enjoy some of these foods without unhealthy weight gain.

Preventing Dental Caries Children frequently snack on sticky, sugary foods that stay on the teeth and provide an ideal environment for the growth of bacteria that cause dental caries. Teach children to brush and floss after meals, to brush or rinse after eating snacks, to avoid sticky foods, and to select crisp or fibrous foods frequently.

Serving as Role Models In an effort to practice these many tips, parents may overlook perhaps the single most important influence on their children's food habits—themselves.[105] Parents who don't eat carrots shouldn't be surprised when their children refuse to eat carrots. Likewise, parents who comment negatively on the smell of brussels sprouts may not be able to persuade children to try them. Children learn much through imitation. It is not surprising that children prefer the foods other family members enjoy and dislike foods that are never offered to them.[106] Parents, older

TABLE 15-8 Healthful Snack Ideas—Think Food Groups, Alone and in Combination

Selecting two or more foods from different food groups adds variety and nutrient balance to snacks. The combinations are endless, so be creative. Whenever possible, choose whole grains, low-fat or reduced-fat milk products, and lean meats.

Grains

Grain products are filling snacks, especially when combined with other foods:

- Cereal with fruit and milk
- Crackers and cheese
- Whole-grain toast with peanut butter
- Popcorn with grated cheese
- Oatmeal raisin cookies with milk

Vegetables

Cut-up, fresh, raw vegetables make great snacks alone or in combination with foods from other food groups:

- Celery with peanut butter
- Broccoli, cauliflower, and carrot sticks with a flavored cottage cheese dip

Fruits

Fruits are delicious snacks and can be eaten alone—fresh, dried, or juiced—or combined with other foods:

- Apples and cheese
- Bananas and peanut butter
- Peaches with yogurt
- Raisins mixed with sunflower seeds or nuts

Meats and Legumes

Meats and legumes add protein to snacks:

- Refried beans with nachos and cheese
- Tuna on crackers
- Luncheon meat on whole-grain bread

Milk and Milk Products

Milk can be used as a beverage with any snack, and many other milk products, such as yogurt and cheese, can be eaten alone or with other foods as listed above.

siblings, and other caregivers set an irresistible example by sitting with younger children, eating the same foods, and having pleasant conversations during mealtimes.

While serving and enjoying food, caregivers can promote both physical and emotional growth at every stage of a child's life. They can help their children develop both a positive self-concept and a positive attitude toward food. With good beginnings, children will grow without the conflicts and confusions about food that can lead to nutrition and health problems.

Nutrition at School

While parents are doing what they can to establish good eating habits in their children at home, others are preparing and serving foods to their children at day-care centers and schools. In addition, children begin to learn about food and nutrition in the classroom. Meeting the nutrition and education needs of children is critical to supporting their healthy growth and development.[107] ◆

Meals at School The U.S. government assists schools financially so that every student can receive nutritious meals at school. Both the School Breakfast Program and

◆ The American Dietetic Association has set nutrition standards for child-care programs. Among them, meal plans should include the following:
- Be nutritionally adequate and consistent with the *Dietary Guidelines for Americans*
- Involve parents in planning
- Follow recommended meal patterns that balance energy and nutrients with children's ages, appetites, activity levels, and special needs while respecting cultural and ethnic differences
- Minimize added fat, sugar, and sodium
- Emphasize fresh fruit, fresh and frozen vegetables, and whole grains
- Provide furniture and eating utensils that are age appropriate and developmentally suitable to encourage children to accept and enjoy mealtime

© David Frazier/PhotoEdit

School lunches provide children with nourishment at little or no charge.

the National School Lunch Program provide meals at a reasonable cost to children from families with the financial means to pay. Meals are available free or at reduced cost to children from low-income families. In addition, schools can obtain food commodities. Nationally, the U.S. Department of Agriculture (USDA) administers the programs; on the state level, state departments of education operate them.* The programs usually cost local school districts little, but the educational rewards are great. Several studies have reported that children who participate in school food programs perform better in the classroom.[108]

More than 28 million children receive lunches through the National School Lunch Program—half of them free or at a reduced price.[109] School lunches offer a variety of food choices and help children meet at least one-third of their recommended intakes for energy, protein, vitamin A, vitamin C, iron, and calcium. Table 15-9 shows school lunch patterns for children of different ages and specifies the numbers of servings of milk, protein-rich foods (meat, poultry, fish, cheese, eggs, legumes, or peanut butter), vegetables, fruits, and breads or other grain foods. In an effort to help reduce disease risk, all government-funded meals served at schools must follow the *Dietary Guidelines for Americans*.

Parents often rely on school lunches to meet a significant part of their children's nutrient needs on school days. Indeed, students who regularly eat school lunches have higher intakes of many nutrients and fiber than students who do not.[110]

The School Breakfast Program ◆ is available in more than 80 percent of the nation's schools that offer school lunch, and close to 9 million children participate in it.[111] Nevertheless, for many children who need it, the School Breakfast Program is either unavailable, or the children do not participate in it.[112] The majority of children who eat school breakfasts are from low-income families. As research results continue to emphasize the positive impact breakfast has on school performance and health, vigorous campaigns to expand school breakfast programs are under way.

◆ The school breakfast must contain at a minimum:
- One serving of fluid milk
- One serving of fruit or vegetable or full-strength juice
- Two servings of bread or bread alternates; or two servings of meat or meat alternates; or one of each

* School lunches in Canada are administered locally and therefore vary from area to area.

TABLE 15-9 School Lunch Patterns for Different Ages[a]

Food Group	Preschool (Age)		Grade School through High School (Grade)		
	1 to 2	3 to 4	K to 3	4 to 6	7 to 12
Meat or meat alternate 1 serving:					
Lean meat, poultry, or fish	1 oz	1½ oz	1½ oz	2 oz	3 oz
Cheese	1 oz	1½ oz	1½ oz	2 oz	3 oz
Large egg(s)	½	¾	¾	1	1½
Cooked dry beans or peas	¼ c	⅜ c	⅜ c	½ c	¾ c
Peanut butter	2 tbs	3 tbs	3 tbs	4 tbs	6 tbs
Yogurt	½ c	¾ c	¾ c	1 c	1½ c
Peanuts, soynuts, tree nuts, or seeds[b]	½ oz	¾ oz	¾ oz	1 oz	1½ oz
Vegetable and/or fruit 2 or more servings, both to total	½ c	½ c	½ c	¾ c	¾ c
Bread or bread alternate[c] Servings	5/week	8/week	8/week	8/week	10/week
Milk 1 serving of fluid milk	¾ c	¾ c	1 c	1 c	1 c

[a]The quantities listed represent per-lunch minimums for each age and grade except those for the oldest group, which are recommendations. Schools unable to serve the recommended quantities for grades 7 to 12 must provide at least the amount shown for grades 4 to 6.
[b]These meat alternates may be used to meet no more than half of the meat or meat alternate requirement; therefore, they must be used in a meal with another meat or meat alternate.
[c]Schools must serve daily at least ½ serving of bread or bread alternate to the youngest age group and at least 1 serving to older children.
SOURCE: U.S. Department of Agriculture, National School Lunch Program Regulations, revised January 1, 1998.

Another federal program, the Child and Adult Care Food Program (CACFP), operates similarly and provides funds to organized child-care programs. All eligible children, centers, and family day-care homes may participate. Sponsors are reimbursed for most meal costs and may also receive USDA commodity foods.

Competing Influences at School Serving healthful lunches is only half the battle; students need to eat them, too. Short lunch periods and long waiting lines prevent some students from eating a school lunch and leave others with too little time to complete their meals.[113] Nutrition efforts at schools are also undermined when students can buy what the USDA labels "competitive foods"—meals from fast-food restaurants or a la carte foods such as pizza or snack foods and carbonated beverages from snack bars, school stores, and vending machines.[114] In one study, students who selected competitive foods in addition to, or instead of, school meals consumed more energy and fat and less calcium and vitamin A than those who selected only the school lunch.[115]

Increasingly, school-based nutrition issues are being addressed by legislation. Some states restrict the sale of competitive foods and have higher rates of participation in school meal programs than the national average. Federal legislation mandates that all school districts that participate in the USDA's National School Lunch Program develop and put in place a local wellness policy.[116] Nutrition professionals advocate further legislative measures that would prohibit sales of food and beverages from vending machines or school stores in middle and high schools until 30 minutes after the end of the last meal unless they are part of the school foodservice and meet *Dietary Guidelines* standards.[117] Reducing the prices of nutritious foods also greatly increases the likelihood that students will purchase them.[118]

IN SUMMARY

Children's appetites and nutrient needs reflect their stage of growth. Those who are chronically hungry and malnourished suffer growth retardation; when hunger is temporary and nutrient deficiencies are mild, the problems are usually more subtle—such as poor academic performance. Iron deficiency is widespread and has many physical and behavioral consequences. "Hyper" behavior is not caused by poor nutrition; misbehavior may be due to lack of sleep, too little physical activity, or too much television, among other things. Childhood obesity has become a major health problem. Adults at home and at school need to provide children with nutrient-dense foods and teach them how to make healthful diet and activity choices.

Nutrition during Adolescence

Teenagers make many more choices for themselves than they did as children. They are not fed, they eat; they are not sent out to play, they choose to go. At the same time, social pressures thrust choices at them, such as whether to drink alcoholic beverages and whether to develop their bodies to meet extreme ideals of slimness or athletic prowess. Their interest in nutrition—both valid information and misinformation—derives from personal, immediate experiences. They are concerned with how diet can improve their lives now—they engage in fad dieting in order to fit into a new bathing suit, avoid greasy foods in an effort to clear acne, or eat a pile of spaghetti to prepare for a big sporting event. In presenting information on the nutrition and health of adolescents, this section includes many topics of interest to teens.

Growth and Development

With the onset of **adolescence,** the steady growth of childhood speeds up abruptly and dramatically, and the growth patterns of female and male become distinct.

adolescence: the period from the beginning of puberty until maturity.

Image Source/Getty Images

Nutritious snacks contribute valuable nutrients to an active teen's diet.

Hormones direct the intensity of the adolescent growth spurt, profoundly affecting every organ of the body, including the brain. After two to three years of intense growth and a few more at a slower pace, physically mature adults emerge.

In general, the adolescent growth spurt begins at age 10 or 11 for females and at 12 or 13 for males. It lasts about two and a half years. Before **puberty,** male and female body compositions differ only slightly, but during the adolescent spurt, differences between the genders become apparent in the skeletal system, lean body mass, and fat stores. In females, fat assumes a larger percentage of the total body weight, and in males, the lean body mass—principally muscle and bone—increases much more than in females (review Figure 8-8, p. 261). On average, males grow 8 inches taller, and females, 6 inches taller. Males gain approximately 45 pounds, and females, about 35 pounds.

Energy and Nutrient Needs

Energy and nutrient needs are greater during adolescence than at any other time of life, except pregnancy and lactation. In general, nutrient needs rise throughout childhood, peak in adolescence, and then level off or even diminish as the teen becomes an adult.

Energy Intake and Activity The energy needs of adolescents vary greatly, depending on their current rate of growth, gender, body composition, and physical activity.[119] Boys' energy needs may be especially high; they typically grow faster than girls and, as mentioned, develop a greater proportion of lean body mass. An exceptionally active boy of 15 may need 3500 kcalories or more a day just to maintain his weight. Girls start growing earlier than boys and attain shorter heights and lower weights, so their energy needs peak sooner and decline earlier than those of their male peers. A sedentary girl of 15 whose growth is nearly at a standstill may need fewer than 1800 kcalories a day if she is to avoid excessive weight gain. Thus adolescent girls need to pay special attention to being physically active and selecting foods of high nutrient density so as to meet their nutrient needs without exceeding their energy needs.

Dietary Guidelines for Americans 2005

Adolescents should engage in at least 60 minutes of physical activity on most, preferably all, days of the week.

The insidious problem of obesity becomes ever more apparent in adolescence and often continues into adulthood. The problem is most evident in females of African American descent and in Hispanic children of both genders. Without intervention, overweight adolescents face numerous physical and socioeconomic consequences for years to come. The consequences of obesity are so dramatic and our society's attitude toward obese people is so negative that even teens of normal or below-normal weight may perceive a need to lose weight. When taken to extremes, restrictive diets bring dramatic physical consequences of their own, as Highlight 8 explained.

Vitamins The RDA (or AI) for most vitamins increases during the adolescent years (see the table on the inside front cover). Several of the vitamin recommendations for adolescents are similar to those for adults, including the recommendation for vitamin D. During puberty, both the activation of vitamin D and the absorption of calcium are enhanced, thus supporting the intense skeletal growth of the adolescent years without additional vitamin D.

Iron The need for iron increases during adolescence for both females and males, but for different reasons. Iron needs increase for females as they start to menstruate

puberty: the period in life in which a person becomes physically capable of reproduction.

and for males as their lean body mass develops. Hence, the RDA increases at age 14 for both males and females. For females, the RDA remains high into late adulthood. For males, the RDA returns to preadolescent values in early adulthood.

In addition, iron needs increase when the adolescent growth spurt begins, whether that occurs before or after age 14. Therefore, boys in a growth spurt need an additional 2.9 milligrams of iron per day above the RDA for their age; girls need an additional 1.1 milligrams per day.[120]

Furthermore, iron recommendations for girls before age 14 do not reflect the iron losses of menstruation. The average age of menarche (first menstruation) in the United States is 12.5 years, however.[121] Therefore, for girls under the age of 14 who have started to menstruate, an additional 2.5 milligrams of iron per day is recommended.[122] Thus the RDA for iron depends not only on age and gender but also on whether the individual is in a growth spurt or has begun to menstruate, as listed in the margin. ◆

◆ Iron RDA for males:
- 9–13 yr: 8 mg/day
- 9–13 yr in growth spurt: 10.9 mg/day
- 14–18 yr: 11 mg/day
- 14–18 yr in growth spurt: 13.9 mg/day

Iron RDA for females:
- 9–13 yr: 8 mg/day
- 9–13 yr in menarche: 10.5 mg/day
- 9–13 yr in menarche and growth spurt: 11.6 mg/day
- 14–18 yr: 15 mg/day
- 14–18 yr in growth spurt: 16.1 mg/day

Iron intakes often fail to keep pace with increasing needs, especially for females, who typically consume less iron-rich foods such as meat and fewer total kcalories than males. Not surprisingly, iron deficiency is most prevalent among adolescent girls. Iron-deficient children and teens score lower on standardized tests than those who are not iron deficient.

Calcium Adolescence is a crucial time for bone development, and the requirement for calcium reaches its peak during these years.[123] Unfortunately, low calcium intakes among adolescents have reached crisis proportions: 90 percent of females and 70 percent of males ages 12 to 19 years have calcium intakes below recommendations.[124] Low calcium intakes during times of active growth, especially if paired with physical inactivity, can compromise the development of peak bone mass, which is considered the best protection against adolescent fractures and adult osteoporosis. Increasing milk products in the diet to meet calcium recommendations greatly increases bone density.[125] Once again, however, teenage girls are most vulnerable, for their milk—and therefore their calcium—intakes begin to decline at the time when their calcium needs are greatest.[126] Furthermore, women have much greater bone losses than men in later life. In addition to dietary calcium, bones grow stronger with physical activity. However, because few high schools require students to attend physical education classes, most adolescents must make a point to be physically active during leisure time.

Dietary Guidelines for Americans 2005

Children 9 years of age and older should consume 3 cups per day of fat-free or low-fat milk or equivalent milk products.

Food Choices and Health Habits

Teenagers like the freedom to come and go as they choose. They eat what they want if it is convenient and if they have the time.[127] With a multitude of afterschool, social, and job activities, they almost inevitably fall into irregular eating habits. At any given time on any given day, a teenager may be skipping a meal, eating a snack, preparing a meal, or consuming food prepared by a parent or restaurant. Adolescents who frequently eat meals with their families, however, eat more fruits, vegetables, grains, and calcium-rich foods, and drink fewer soft drinks, than those who seldom eat with their families.[128] Furthermore, the more often teenagers eat dinner with their families, the less likely they are to smoke, drink, or use drugs.[129] Many adolescents also begin to skip breakfast on a regular basis, missing out on important nutrients that are not made up at later meals during the day. Compared with those who skip breakfast, teenagers who do eat breakfast have higher intakes of vitamins A, C, and riboflavin, as well as calcium, iron, and zinc.[130] Teenagers who eat breakfast are therefore more likely to meet their nutrient intake recommendations.

© White Packert/Getty Images

Because their lunches rarely include fruits, vegetables, or milk, many teens fail to get all the vitamins and minerals they need each day.

Ideally, in light of adolescents' busy schedules and desire for freedom, the adult continues to play the role of gatekeeper, controlling the type and availability of food in the teenager's environment. Teenagers should find plenty of nutritious, easy-to-grab foods in the refrigerator (meats for sandwiches; low-fat cheeses; fresh, raw vegetables and fruits; fruit juices; and milk) and more in the cabinets (whole-grain breads, peanut butter, nuts, popcorn, and cereal). In many households today, the adults work outside the home, and teenagers perform some of the gatekeepers' roles, such as shopping for groceries or choosing fast or prepared foods.

Snacks Snacks typically provide at least a fourth of the average teenager's daily food energy intake. Most often, favorite snacks are too high in saturated fat and sodium and too low in fiber to support the future health of the arteries.[131] Table 15-8, p. 541 shows how to combine foods from different food groups to create healthy snacks.

Beverages Most frequently, adolescents drink soft drinks instead of fruit juice or milk with lunch, supper, and snacks. About the only time they select fruit juices is at breakfast. When teens drink milk, they are more likely to consume it with a meal (especially breakfast) than as a snack. Soft drinks, when chosen as the primary beverage, may affect bone density because they displace milk from the diet.[132] Because of their greater food intakes, boys are more likely than girls to drink enough milk to meet their calcium needs.

Over the past three decades, teens (especially girls) have been drinking more soft drinks and less milk.[133] Adolescents who drink soft drinks regularly have a higher energy intake and a lower calcium intake than those who do not; they are also more likely to be overweight.[134]

Soft drinks containing caffeine present a different problem if caffeine ◆ intake becomes excessive. Caffeine seems to be relatively harmless when used in moderate doses (the equivalent of fewer than three 12-ounce cola beverages a day). In greater amounts, however, it can cause the symptoms associated with anxiety, such as sweating, tenseness, and inability to concentrate.

◆ For perspective, caffeine-containing soft drinks typically deliver between 30 and 55 mg of caffeine per 12-ounce can. A pharmacologically active dose of caffeine is defined as 200 mg. Appendix H starts with a table listing the caffeine contents of selected foods, beverages, and drugs.

Eating Away from Home Adolescents eat about one-third of their meals away from home, and their nutritional welfare is enhanced or hindered by the choices they make. A lunch consisting of a hamburger, a chocolate shake, and French fries supplies substantial quantities of many nutrients at a kcalorie cost of about 800, an energy intake some adolescents can afford. When they eat this sort of lunch, teens can adjust their breakfast and dinner choices to include fruits and vegetables for vitamin A, vitamin C, folate, and fiber and lean meats and legumes for iron and zinc. (See Appendix H for the nutrient contents of fast foods.) Fortunately, many fast-food restaurants are offering more nutritious choices than the standard hamburger meal.

Peer Influence Many of the food and health choices adolescents make reflect the opinions and actions of their peers. When others perceive milk as "babyish," a teen may choose soft drinks instead; when others skip lunch and hang out in the parking lot, a teen may join in for the camaraderie, regardless of hunger. Adults need to remember that adolescents have the right to make their own decisions—even if they are contrary to the adults' views. Gatekeepers can set up the environment so that nutritious foods are available and can stand by with reliable nutrition information and advice, but the rest is up to the adolescents. Ultimately, they make the choices. (Highlight 8 examines the influence of social pressures on the development of eating disorders.)

Problems Adolescents Face

Physical maturity and growing independence present adolescents with new choices. The consequences of those choices will influence their nutritional health both today and throughout life. Some teenagers begin using drugs, alcohol, and tobacco; others wisely refrain. Information about the use of these substances is presented here because most people are first exposed to them during adolescence, but it actually applies to people of all ages.

Marijuana Almost half of the high school students in the United States report having at least tried marijuana.[135] Marijuana is unique among drugs in that it seems to enhance the enjoyment of eating, especially of sweets, a phenomenon commonly known as "the munchies." Prolonged use of marijuana, however, does not seem to bring about a weight gain.

Cocaine, Crack, and Methamphetamine Cocaine, crack, and methamphetamine stimulate the nervous system and elicit the stress response—constricted blood vessels, raised blood pressure, dilated pupils, and increased body temperature. These drugs also drive away feelings of fatigue. They occasionally cause immediate death—usually by heart attack, stroke, or seizure in an already damaged body system. During prolonged episodes of drug use, abusers suffer dehydration and electrolyte imbalances. Decreases in appetite, weight loss, and malnutrition are common. Notably, the craving for these drugs replaces hunger; rats given unlimited cocaine will choose it over food until they starve to death. Thus, unlike marijuana use, cocaine, crack, and methamphetamine use has major nutritional consequences.

Ecstasy The club drug ecstasy has become alarmingly popular in recent years. Ecstasy signals the nerve cells to dump all their stored serotonin ◆ at once and then prevents its reabsorption. The rush of serotonin flooding the gap between the nerve cells (the *synapse*) alters a person's mood, but it may also damage nerve cells and impair memory. Because serotonin helps to regulate body temperature, overheating is a common and potentially dangerous side effect of this drug. People who use ecstasy regularly tend to lose weight.

◆ Reminder: *Serotonin* is a neurotransmitter important in the regulation of appetite, sleep, and body temperature.

Drug Abuse, in General The nutrition problems associated with other drugs vary in degree, but drug abusers in general face multiple nutrition problems. ◆ During withdrawal from drugs, an important part of treatment is to identify and correct nutrient deficiencies.

◆ Nutrition problems of drug abusers:
- They buy drugs with money that could be spent on food.
- They lose interest in food during "highs."
- They use drugs that suppress appetite.
- Their lifestyle fails to promote good eating habits.
- If they use intravenous (IV) drugs, they may contract AIDS, hepatitis, or other infectious diseases, which increase their nutrient needs. Hepatitis also causes taste changes and loss of appetite.
- Medicines used to treat drug abuse may alter nutrition status.

Alcohol Abuse Sooner or later all teenagers face the decision of whether to drink alcohol. The law forbids the sale of alcohol to people under 21, but most adolescents who want it can get it. By the end of high school, 77 percent of students have tried alcohol, and about half have been drunk at least once.[136] Highlight 7 describes how alcohol affects nutrition status. To sum it up, alcohol provides energy but no nutrients, and it can displace nutritious foods from the diet. Alcohol alters nutrient absorption and metabolism, so imbalances develop. People who cannot keep their alcohol use moderate must abstain to maintain their health. Highlight 7 lists resources for people with alcohol-related problems.

Smoking Slightly less than 30 percent of U.S. high school students report smoking a cigarette in the previous month.[137] This is the lowest rate of smoking among high school students since 1991. Cigarette smoking is a pervasive health problem causing thousands of people to suffer from cancer and diseases of the cardiovascular, digestive, and respiratory systems. These effects are beyond the scope of nutrition, but smoking cigarettes does influence hunger, body weight, and nutrient status.

Smoking a cigarette eases feelings of hunger. When smokers receive a hunger signal, they can quiet it with cigarettes instead of food. Such behavior ignores body signals and postpones energy and nutrient intake. Indeed, smokers tend to weigh less than nonsmokers and to gain weight when they stop smoking. People contemplating giving up cigarettes should know that the average weight gain is about 10 pounds in the first year. Smokers wanting to quit should prepare for the possibility of weight gain and adjust their diet and activity habits so as to maintain weight during and after quitting. Smoking cessation programs need to include strategies for weight management.

Nutrient intakes of smokers and nonsmokers differ. Smokers tend to have lower intakes of dietary fiber, vitamin A, beta-carotene, folate, and vitamin C. The association between smoking and low intakes of fruits and vegetables rich in these nutrients may be noteworthy, considering their protective effect against lung cancer (see Highlight 11).

◆ The vitamin C requirement for people who regularly smoke cigarettes is an additional 35 mg/day.

Compared with nonsmokers, smokers require more vitamin C ◆ to maintain steady body pools. Oxidants in cigarette smoke accelerate vitamin C metabolism and deplete smokers' body stores of this antioxidant. This depletion is even evident to some degree in nonsmokers who are exposed to passive smoke.[138]

Beta-carotene enhances the immune response and protects against some cancer activity. Specifically, the risk of lung cancer is greatest for smokers who have the lowest intakes. Of course, such evidence should not be misinterpreted. It does not mean that as long as people eat their carrots, they can safely use tobacco. Nor does it mean that beta-carotene *supplements* are beneficial; smokers taking beta-carotene supplements actually had a higher incidence of lung cancer and risk of death than those taking a placebo. (See Highlight 11 for more details.) Smokers are ten times more likely to get lung cancer than nonsmokers. Both smokers and nonsmokers, however, can reduce their cancer risks by eating fruits and vegetables rich in antioxidants. (See Highlight 11 for details on antioxidant nutrients and disease prevention.)

Smokeless Tobacco Like cigarettes, smokeless tobacco use is linked to many health problems, from minor mouth sores to tumors in the nasal cavities, cheeks, gums, and throat. The risk of mouth and throat cancers is even greater than for smoking tobacco. Other drawbacks to tobacco chewing and snuff dipping include bad breath, stained teeth, and blunted senses of smell and taste. Tobacco chewing also damages the gums, tooth surfaces, and jawbones, making teeth loss later in life likely.

The nutrition and lifestyle choices people make as children and adolescents have long-term, as well as immediate, effects on their health. Highlight 15 describes how sound choices and good habits during childhood and adolescence can help prevent chronic diseases later in life.

Nutrition Portfolio

Encouraging children to eat nutritious foods today helps them learn how to make healthy food choices tomorrow.

- If there are children in your life, think about the food they eat and consider whether they receive enough food for healthy growth, but not so much as to lead to obesity.
- Describe the advantages of physical activity to children's health and well-being.
- Plan a day's menu for a child 4 to 8 years of age, making sure to include foods that provide enough calcium and iron.

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Describe some of the nutrient and immunological attributes of breast milk. (pp. 518–520)
2. What are the appropriate uses of formula feeding? What criteria would you use in selecting an infant formula? (pp. 520–521)
3. Why are solid foods not recommended for an infant during the first few months of life? When is an infant ready to start eating solid food? (pp. 523–525)
4. Identify foods that are inappropriate for infants and explain why they are inappropriate. (pp. 522, 524–525)
5. What nutrition problems are most common in children? What strategies can help prevent these problems? (pp. 530–532)
6. Describe the relationships between nutrition and behavior. How does television influence nutrition? (pp. 532–533, 537)
7. Describe a true food allergy. Which foods most often cause allergic reactions? How do food allergies influence nutrition status? (pp. 533–535)
8. Describe the problems associated with childhood obesity and the strategies for prevention and treatment. (pp. 535–539)
9. List strategies for introducing nutritious foods to children. (pp. 539–541)
10. What impact do school meal programs have on the nutrition status of children? (pp. 541–543)
11. Describe the changes in nutrient needs from childhood to adolescence. Why is an adolescent girl more likely to develop an iron deficiency than is a boy? (pp. 543–545)
12. How do adolescents' eating habits influence their nutrient intakes? (pp. 545–546)
13. How does the use of illicit drugs influence nutrition status? (p. 547)
14. How do the nutrient intakes of smokers differ from those of nonsmokers? What impacts can those differences exert on health? (pp. 547–548)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 553.

1. A reasonable weight for a healthy five-month-old infant who weighed 8 pounds at birth might be:
   a. 12 pounds.
   b. 16 pounds.
   c. 20 pounds.
   d. 24 pounds.

2. Dehydration can develop quickly in infants because:
   a. much of their body water is extracellular.
   b. they lose a lot of water through urination and tears.
   c. only a small percentage of their body weight is water.
   d. they drink lots of breast milk or formula, but little water.
3. An infant should begin eating solid foods between:
   a. 2 and 4 weeks.
   b. 1 and 3 months.
   c. 4 and 6 months.
   d. 8 and 10 months.
4. Among U.S. and Canadian children, the most prevalent nutrient deficiency is of:
   a. iron.
   b. folate.
   c. protein.
   d. vitamin D.
5. A true food allergy always:
   a. elicits an immune response.
   b. causes an immediate reaction.
   c. creates an aversion to the offending food.
   d. involves symptoms such as headaches or hives.
6. Which of the following strategies is *not* effective?
   a. Play first, eat later.
   b. Provide small portions.
   c. Encourage children to help prepare meals.
   d. Use dessert as a reward for eating vegetables.
7. To help teenagers consume a balanced diet, parents can:
   a. monitor the teens' food intake.
   b. give up—parents can't influence teenagers.
   c. keep the pantry and refrigerator well stocked.
   d. forbid snacking and insist on regular, well-balanced meals.
8. During adolescence, energy and nutrient needs:
   a. reach a peak.
   b. fall dramatically.
   c. rise, but do not peak until adulthood.
   d. fluctuate so much that generalizations can't be made.
9. The nutrients most likely to fall short in the adolescent diet are:
   a. sodium and fat.
   b. folate and zinc.
   c. iron and calcium.
   d. protein and vitamin A.
10. To balance the day's intake, an adolescent who eats a hamburger, fries, and cola at lunch might benefit most from a dinner of:
   a. fried chicken, rice, and banana.
   b. ribeye steak, baked potato, and salad.
   c. pork chop, mashed potatoes, and apple juice.
   d. spaghetti with meat sauce, broccoli, and milk.

Childhood Obesity and the Early Development of Chronic Diseases

© Ross Whitaker/The Images Bank/Getty Images

When people think about the health problems of children and adolescents, they typically think of ear infections, colds, and acne—not heart disease, diabetes, or hypertension. Today, however, unprecedented numbers of U.S. children are being diagnosed with obesity and the serious "adult diseases," such as type 2 diabetes, that accompany overweight.[1] When type 2 diabetes develops before the age of 20, the incidence of diabetic kidney disease and death in middle age increases dramatically, largely because of the long duration of the disease.[2] For children born in the United States in the year 2000, the risk of developing type 2 diabetes sometime in their lives is estimated to be 30 percent for boys and 40 percent for girls.[3] U.S. children are not alone—rapidly rising rates of obesity threaten the health of an alarming number of children around the globe.[4] Without immediate intervention, millions of children are destined to develop type 2 diabetes and hypertension in childhood followed by **cardiovascular disease (CVD)** in early adulthood.

This highlight focuses on efforts to prevent childhood obesity and the development of heart disease and type 2 diabetes, but the benefits extend to other obesity-related diseases as well. The years of childhood (ages 2 to 18) are emphasized here, because the earlier in life health-promoting habits become established, the better they will stick. Chapters 26 and 27 fill in the rest of the story of nutrition's role in the development and treatment of diabetes and heart disease, respectively.

Invariably, questions arise as to what extent genetics is involved in disease development. For heart disease and type 2 diabetes, genetics does not appear to play a *determining* role; that is, a person is not simply destined at birth to develop these diseases. Instead, genetics appears to play a *permissive* role—the potential is inherited and will develop if given a push by poor health choices such as excessive weight gain, poor diet, sedentary lifestyle, and cigarette smoking.

Many experts agree that preventing or treating obesity in childhood will reduce the rate of chronic diseases in adulthood. Without intervention, most overweight children become overweight adolescents who become overweight adults, and being overweight exacerbates every chronic disease that adults face.[5]

Early Development of Type 2 Diabetes

In recent years, type 2 diabetes, a chronic disease closely linked with obesity, has been on the rise among children and adolescents as the prevalence of obesity in U.S. youth has increased.[6] Obesity is the most important risk factor for type 2 diabetes—most of the children diagnosed with it are obese.[7] Most are diagnosed during puberty, but as children become more obese and less active, the trend is shifting to younger children. Type 2 diabetes is most likely to occur in those who are obese and sedentary and have a family history of diabetes.

In type 2 diabetes, the cells become insulin-resistant—that is, the cells become less sensitive to insulin, reducing the amount of glucose entering the cells from the blood. The combination of obesity and insulin resistance produces a cluster of symptoms, including high blood cholesterol and high blood pressure, which, in turn, promotes the development of atherosclerosis and the early development of CVD.[8] Other common problems evident by early adulthood include kidney disease, blindness, and miscarriages. The complications of diabetes, especially when encountered at a young age, can shorten life expectancy.

Prevention and treatment of type 2 diabetes depend on weight management, which can be particularly difficult in a youngster's world of food advertising, video games, and pocket money for candy bars. The activity and dietary suggestions to help defend against heart disease later in this highlight apply to type 2 diabetes as well.

Early Development of Heart Disease

Most people consider heart disease to be an adult disease because its incidence rises with advancing age, and symptoms rarely appear before age 30. The disease process actually begins much earlier.

Atherosclerosis

Most cardiovascular disease involves **atherosclerosis** (see the glossary, p. 555 for this and related terms). Atherosclerosis develops when regions of an artery's walls become progressively thickened with **plaque**—an accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue. If it progresses, atherosclerosis may eventually block the flow of blood to the heart and cause a heart attack or cut off blood flow to the brain and cause a stroke. Infants are born with healthy, smooth, clear arteries, but within the first decade of life, **fatty streaks** may begin to appear

GLOSSARY

atherosclerosis (ATH-er-oh-scler-OH-sis): a type of artery disease characterized by plaques (accumulations of lipid-containing material) on the inner walls of the arteries (see Chapter 27).
- **athero** = porridge or soft
- **scleros** = hard
- **osis** = condition

cardiovascular disease (CVD): a general term for all diseases of the heart and blood vessels. Atherosclerosis is the main cause of CVD. When the arteries that carry blood to the heart muscle become blocked, the heart suffers damage known as **coronary heart disease (CHD).**
- **cardio** = heart
- **vascular** = blood vessels

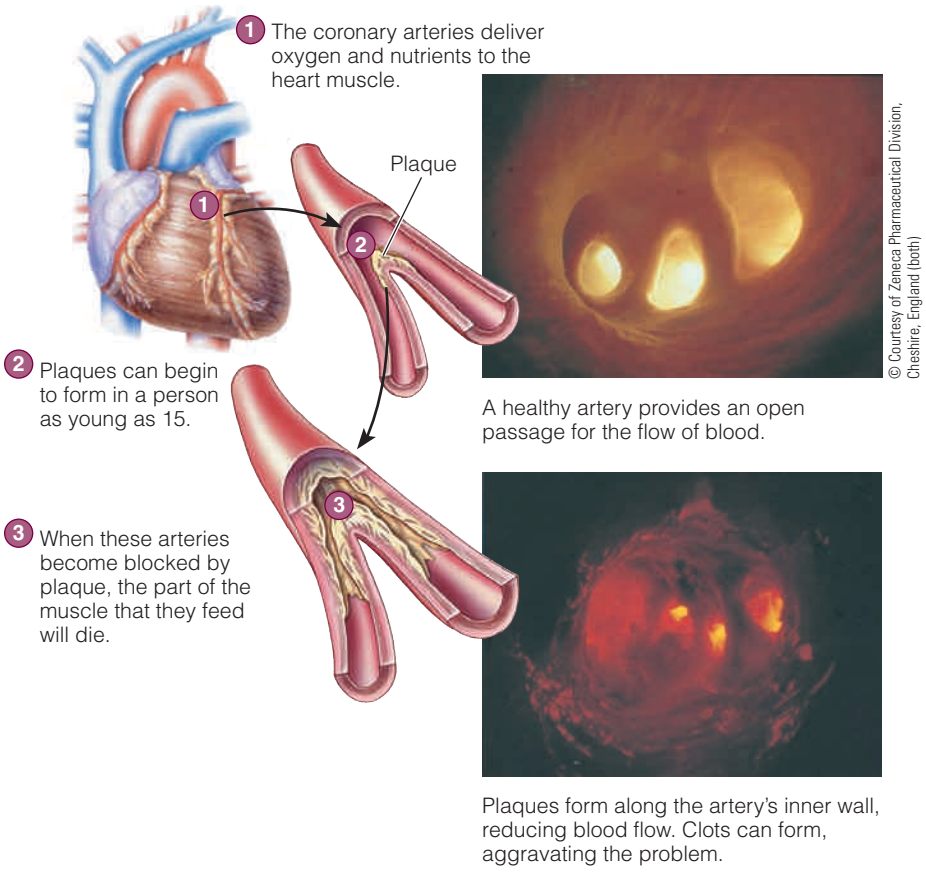
fatty streaks: accumulations of cholesterol and other lipids along the walls of the arteries.

plaque (PLACK): an accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue that develops in the artery walls in atherosclerosis. Plaque associated with atherosclerosis is known as **atheromatous** (ATH-er-OH-ma-tus) **plaque.**

(see Figure H15-1). During adolescence, these fatty streaks may begin to accumulate fibrous connective tissue. By early adulthood, the fibrous plaques may begin to calcify and become raised lesions, especially in boys and young men. As the lesions grow more numerous and enlarge, the heart disease rate begins to rise, most dramatically at about age 45 in men and 55 in women. From this point on, arterial damage and blockage progress rapidly, and heart attacks and strokes threaten life. In short, the consequences of atherosclerosis, which become apparent only in adulthood, have their beginnings in the first decades of life.[9]

Atherosclerosis is not inevitable; people can grow old with relatively clear arteries. Early lesions may either progress or regress, depending on several factors, many of which reflect lifestyle behaviors. Smoking, for example, is strongly associated with the prevalence of fatty streaks and raised lesions, even in young adults.

FIGURE H15-1 The Formation of Plaques in Atherosclerosis



Blood Cholesterol

As blood cholesterol rises, atherosclerosis worsens. Cholesterol values at birth are similar in all populations; differences emerge in early childhood. Standard values for cholesterol in children and adolescents (ages 2 to 18 years) are listed in Table H15-1 (p. 556).

In general, blood cholesterol tends to rise as dietary saturated fat intakes increase. Blood cholesterol also correlates with childhood obesity, especially abdominal obesity.[10] LDL cholesterol rises with obesity, and HDL declines. These relationships are apparent throughout childhood, and their magnitude increases with age.

Children who are both overweight and have high blood cholesterol are likely to have parents who develop heart disease early.[11] For this reason, selective screening is recommended for children and adolescents whose parents (or grandparents) have heart disease; those whose parents have elevated blood cholesterol; and those whose family history is unavailable, especially if other risk factors are evident.[12] Because blood cholesterol in children is a good predictor of adult values, some experts recommend universal screening for all children, and particularly for those who are overweight, smoke, are sedentary, or consume diets high in saturated fat.

Early—but not advanced—atherosclerotic lesions are reversible, making screening and education a high priority. Both those with family histories of heart disease and those with multiple risk factors need intervention. Children with the highest risks of developing heart disease are sedentary and obese, with high blood pressure and high blood cholesterol.[13] In contrast, children with the lowest risks of heart disease are physically active and of normal weight, with low blood pressure and favorable lipid profiles. Routine pediatric care should identify these known risk factors and provide intervention when needed.

Blood Pressure

Pediatricians routinely monitor blood pressure in children and adolescents. High blood pressure may signal an underlying disease or the early onset of hypertension. Hypertension accelerates the development of atheroscerlosis.[14]

TABLE H15-1 Cholesterol Values for Children and Adolescents

Disease Risk	Total Cholesterol (mg/dL)	LDL Cholesterol (mg/dL)
Acceptable	<170	<100
Borderline	170–199	100–129
High	≥200	≥130

NOTE: Adult values appear in Chapter 27.

Like atherosclerosis and high blood cholesterol, hypertension may develop in the first decades of life, especially among obese children, and worsen with time.[15] Children can control their hypertension by participating in regular aerobic activity and by losing weight or maintaining their weight as they grow taller. Evidence is needed to clarify whether restricting sodium in children's and adolescent's diets lowers blood pressure.

Physical Activity

Research has also confirmed an association between blood lipids and physical activity in children, similar to that seen in adults. Physically active children have a better lipid profile and lower blood pressure than physically inactive children, and these positive findings often persist into adulthood.

Just as blood cholesterol and obesity track over the years, so does a youngster's level of physical activity. Those who are inactive now are likely to still be inactive years later. Similarly, those who are physically active now tend to remain so. Compared with inactive teens, those who are physically active weigh less, smoke less, eat a diet lower in saturated fats, and have better blood lipid profiles. Both obesity and blood cholesterol correlate with the inactive pastime of watching television. The message is clear: physical activity offers numerous health benefits, and children who are active today are most likely to be active for years to come.

Dietary Recommendations for Children

Regardless of family history, experts agree that all children over age two should eat a variety of foods and maintain desirable weight (see Table H15-2). Children (4 to 18 years of age) should receive at least 25 percent and no more than 35 percent of total energy from fat, less than 10 percent from saturated fat, and less than 300 milligrams of cholesterol per day.[16] Recommendations limiting fat and cholesterol are not intended for infants or children under two years old. Infants and toddlers need a higher percentage of fat to support their rapid growth.

TABLE H15-2 American Heart Association Dietary Guidelines and Strategies for Children[a]

- Balance dietary kcalories with physical activity to maintain normal growth.
- Every day, engage in 60 minutes of moderate to vigorous play or physical activity.
- Eat vegetables and fruits daily. Use fresh, frozen, and canned vegetables and fruits and serve at every meal; limit those with added fats, salt, and sugar.
- Limit juice intake (4 to 6 ounces per day for children 1 to 6 years of age, 8 to 12 ounces for children 7 to 18 years of age).
- Use vegetable oils (canola, soybean, olive, safflower, or other unsaturated oils) and soft margarines low in saturated fat and *trans* fatty acids instead of butter or most other animal fats in the diet.
- Choose whole-grain breads and cereals rather than refined products; read labels and make sure that "whole grain" is the first ingredient.
- Reduce the intake of sugar-sweetened beverages and foods.
- Consume low-fat and nonfat milk and milk products daily.
- Include 2 servings of fish per week, especially fatty fish such as broiled or baked salmon.
- Choose legumes and tofu in place of meat for some meals.
- Choose only lean cuts of meat and reduced-fat meat products; remove the skin from poultry.
- Use less salt, including salt from processed foods. Breads, breakfast cereals, and soups may be high in salt and/or sugar so read food labels and choose high-fiber, low-salt, low-sugar alternatives.
- Limit the intake of high-kcalorie add-ons such as gravy, Alfredo sauce, cream sauce, cheese sauce, and hollandaise sauce.
- Serve age-appropriate portion sizes on appropriately sized plates and bowls.

[a] These guidelines are for children 3 years of age and older.

Moderation, Not Deprivation

Healthy children over age two can begin the transition to eating according to recommendations by eating fewer foods high in saturated fat and selecting more fruits and vegetables. Healthy meals can occasionally include moderate amounts of a child's favorite foods, even if they are high in saturated fat such as French fries and ice cream. A steady diet of offerings from some "children's menus" in restaurants such as chicken nuggets, hot dogs, and French fries, easily exceeds a prudent intake of saturated fat, *trans* fat, and kcalories, however, and invites both nutrient shortages and weight gains.[17] Fortunately, most restaurants chains are changing children's menus to include steamed vegetables, fruit cups, and broiled or grilled poultry—additions welcomed by busy parents who often dine out or purchase take-out foods.

Other fatty foods, such as nuts, vegetable oils, and some varieties of fish such as light canned tuna or salmon, are important for

their essential fatty acids. Low-fat milk and milk products also deserve special attention in a child's diet for the needed calcium and other nutrients they supply.[18]

Parents and caregivers play a key role in helping children establish healthy eating habits. Balanced meals need to provide lean meat, poultry, fish, and legumes; fruits and vegetables; whole grains; and low-fat milk products. Such meals can provide enough energy and nutrients to support growth and maintain blood cholesterol within a healthy range.

Pediatricians warn parents to avoid extremes. Although intentions may be good, excessive food restriction may create nutrient deficiencies and impair growth. Furthermore, parental control over eating may instigate battles and foster attitudes about foods that can lead to inappropriate eating behaviors.

Diet First, Drugs Later

Experts agree that children with high blood cholesterol should first be treated with diet. If blood cholesterol remains high in children ten years and older after 6 to 12 months of dietary intervention, then drugs may be necessary to lower blood cholesterol. Drugs can effectively lower blood cholesterol without interfering with adolescent growth or development.[19]

Smoking

Even though the focus of this text is nutrition, another risk factor for heart disease that starts in childhood and carries over into adulthood must also be addressed—cigarette smoking. Each day 3000 children light up for the first time—typically in grade school. Among high school students, almost two out of three have tried smoking, and one in five smokes regularly.[20] Approximately 80 percent of all adult smokers began smoking before the age of 18.

Of those teenagers who continue smoking, half will eventually die of smoking-related causes. Efforts to teach children about the dangers of smoking need to be aggressive. Children are not likely to consider the long-term health consequences of tobacco use. They are more likely to be struck by the immediate health consequences, such as shortness of breath when playing sports, or social consequences, such as having bad breath. Whatever the context, the message to all children and teens should be clear: don't start smoking. If you've already started, quit.

© Janine Wiedel Photolibrary/Alamy

Cigarette smoking is the number one preventable cause of deaths.

In conclusion, *adult* heart disease is a major *pediatric* problem. Without intervention, some 60 million children are destined to suffer its consequences within the next 30 years. Optimal prevention efforts focus on children, especially on those who are overweight.[21]

Just as young children receive vaccinations against infectious diseases, they need screening for, and education about, chronic diseases. Many health education programs have been implemented in schools around the country. These programs are most effective when they include education in the classroom, heart-healthy meals in the lunchroom, fitness activities on the playground, and parental involvement at home.

Nutrition in Your Life

Take a moment to envision yourself 20, 40, or even 60 years from now. Are you physically fit and healthy? Can you see yourself walking on the beach with friends or tossing a ball with children? Are you able to climb stairs and carry your own groceries? Importantly, are you enjoying life? If you're lucky, you will grow old with good health, but much of that depends on your actions today—and every day from now until then. Making nutritious foods and physical activities a priority in your life can help bring rewards of continued health and enjoyment in later life.

CHAPTER 16

Life Cycle Nutrition: Adulthood and the Later Years

CHAPTER OUTLINE

Nutrition and Longevity • Observation of Older Adults • Manipulation of Diet

The Aging Process • Physiological Changes • Other Changes

Energy and Nutrient Needs of Older Adults • Water • Energy and Energy Nutrients • Vitamins and Minerals • Nutrient Supplements

Nutrition-Related Concerns of Older Adults • Vision • Arthritis • The Aging Brain

Food Choices and Eating Habits of Older Adults • Food Assistance Programs • Meals for Singles

HIGHLIGHT 16 Hunger and Community Nutrition

Wise food choices, made throughout adulthood, can support a person's ability to meet physical, emotional, and mental challenges and to enjoy freedom from disease. Two goals motivate adults to pay attention to their diets: promoting health and slowing aging. Much of this text has focused on nutrition to support health, and later chapters feature dietary treatments of diseases. This chapter focuses on aging and the nutrition needs of older adults.

The U.S. population is growing older. The majority is now middle-aged, and the ratio of old people to young is increasing, as Figure 16-1 (p. 562) shows. In 1900, only 1 out of 25 people was 65 or older. In 2000, 1 out of 8 had reached age 65. Projections for 2030 are 1 out of 5.

Our society uses the arbitrary age of 65 years to define the transition point between middle age and old age, but growing "old" happens day by day, with changes occurring gradually over time. Since 1950 the population of those over 65 has almost tripled. Remarkably, the fastest-growing age group has been people over 85 years; since 1950 their numbers have increased sevenfold. The number of people in the United States age 100 or older doubled in the last decade. Similar trends are occurring in populations worldwide.[1]

Life expectancy in the United States for white women is 81 years and for black women, 76 years; for white men, it is 75 years and for black men, 69 years—all record highs and much higher than the average life expectancy of 47 years in 1900.[2] Women who live to 80 can expect to survive an additional 9 years, on average; men, an additional 7 years. Advances in medical science—antibiotics and other treatments—are largely responsible for almost doubling the life expectancy in the 20th century. Improved nutrition and an abundant food supply have also contributed to lengthening life expectancy. The **life span** has not lengthened as dramatically; human **longevity** appears to have an upper limit. The potential human life span is currently 130 years. With recent advances in medical technology

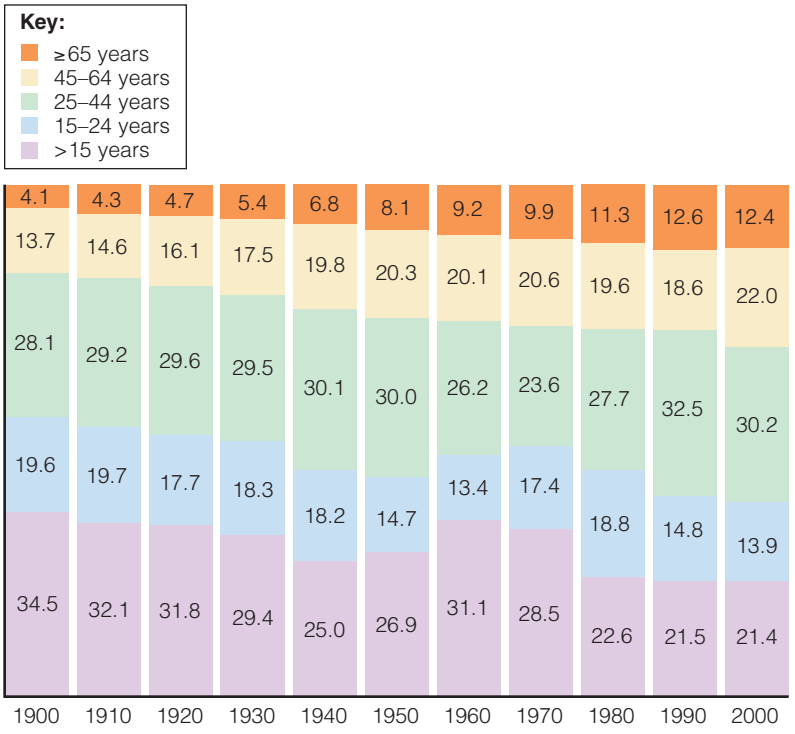
life expectancy: the average number of years lived by people in a given society.

life span: the maximum number of years of life attainable by a member of a species.

longevity: long duration of life.

FIGURE 16-1 The Aging of the U.S. Population

In general, the percentage of older people in the population has increased over the decades whereas the percentage of younger people has decreased.



SOURCE: U.S. Census Bureau, Decennial census of population, 1900 to 2000.

and genetic knowledge, however, researchers may one day be able to extend the life span even further by slowing, or perhaps preventing, aging and its accompanying diseases.[3]

Nutrition and Longevity

Research in the field of aging is active—and difficult. Researchers are challenged by the diversity of older adults. When older adults experience health problems, it is hard to know whether to attribute these problems to genetics, aging, or other environmental factors such as nutrition. The idea that nutrition can influence the aging process is particularly appealing because people can control and change their eating habits. The questions being asked include:

- To what extent is aging inevitable, and can it be slowed through changes in lifestyle and environment?
- What role does nutrition play in the aging process, and what role can it play in slowing aging?

With respect to the first question, it seems that aging is an inevitable, natural process, programmed into the genes at conception.[4] People can, however, slow the process within genetic limits by adopting healthy lifestyle habits such as eating nutritious food and engaging in physical activity. In fact, an estimated 70 to 80 percent of the average person's life expectancy may depend on individual health-related behaviors; genes determine the remaining 20 to 30 percent.[5]

With respect to the second question, good nutrition helps to maintain a healthy body and can therefore ease the aging process in many significant ways. Clearly, nutrition can improve the **quality of life** in the later years.

quality of life: a person's perceived physical and mental well-being.

Observation of Older Adults

The strategies adults use to meet the two goals mentioned at the start of this chapter—promoting health and slowing aging—are actually very much the same. What to eat, when to sleep, how physically active to be, and other lifestyle choices greatly influence both physical health and the aging process.

Healthy Habits A person's **physiological age** reflects his or her health status and may or may not reflect the person's **chronological age.** Quite simply, some people seem younger, and others older, than their years. Six lifestyle behaviors seem to have the greatest influence on people's health and therefore on their physiological age:

- Sleeping regularly and adequately
- Eating well-balanced meals, including breakfast, regularly
- Engaging in physical activity regularly
- Not smoking
- Not using alcohol, or using it in moderation
- Maintaining a healthy body weight

Over the years, the effects of these lifestyle choices accumulate—that is, people who follow most of these practices live longer and have fewer disabilities as they age. They are in better health, even when older in chronological age, than people who do not adopt these behaviors. Even though people cannot change their birth dates, they may be able to add years to, and enhance the quality of, their lives. Physical activity seems to be most influential in preventing or slowing the many changes that define a stereotypical "old" person. After all, many of the physical limitations that accompany aging occur because people become inactive, not because they become older.

Physical Activity The many remarkable benefits of regular physical activity are not limited to the young. Compared with those who are inactive, older adults who are active weigh less; have greater flexibility, more endurance, better balance, and better health; and live longer.[6] They reap additional benefits from various activities as well: aerobic activities improve cardiorespiratory endurance, blood pressure, and blood lipid concentrations; moderate endurance activities improve the quality of sleep; and strength training improves posture and mobility. In fact, regular physical activity is the most powerful predictor of a person's mobility in the later years. Physical activity also increases blood flow to the brain, thereby preserving mental ability, alleviating depression, supporting independence, and improving quality of life.[7]

Dietary Guidelines for Americans 2005

Older adults should participate in regular physical activity to reduce the functional declines associated with aging and to achieve the other benefits of physical activity identified for all adults.

Muscle mass and muscle strength tend to decline with aging, making older people vulnerable to falls and immobility. Falls are a major cause of fear, injury, disability, and even death among older adults.[8] Many lose their independence as a result of falls. Regular physical activity tones, firms, and strengthens muscles, helping to improve confidence, reduce the risk of falling, and lessen the risk of injury should a fall occur.

Even without a fall, older adults may become so weak that they can no longer perform life's daily tasks, such as climbing stairs, carrying packages, and opening jars. By improving muscle strength, which allows a person to perform these tasks, strength training helps to maintain independence. Even in frail, elderly people over

physiological age: a person's age as estimated from her or his body's health and probable life expectancy.

chronological age: a person's age in years from his or her date of birth.

© R. W. Jones/Corbis

Regular physical activity promotes a healthy, independent lifestyle.

85 years of age, strength training not only improves balance, muscle strength, and mobility, but it also increases energy expenditure and energy intake, thereby enhancing nutrient intakes. This finding highlights another reason to be physically active: a person spending energy can afford to eat more food and thus receives more nutrients. People who are committed to an ongoing fitness program can benefit from higher energy and nutrient intakes and still maintain their body weights.

Ideally, physical activity should be part of each day's schedule and should be intense enough to prevent muscle atrophy and to speed up the heartbeat and respiration rate. Although aging reduces both speed and endurance to some degree, older adults can still train and achieve exceptional performances. Healthy older adults who have not been active can ease into a suitable routine. They can start by walking short distances until they are walking at least 10 minutes continuously and then gradually increase their distance to a 30- to 45-minute workout at least 5 days a week. Table 16-1 provides exercise guidelines for seniors. People with medical conditions should check with a physician before beginning an exercise routine, as should sedentary men over 40 and sedentary women over 50 who want to participate in a vigorous program.

Manipulation of Diet

In their efforts to understand longevity, researchers have not only observed people, but they have also manipulated influencing factors, such as diet, in animals. This research has given rise to some interesting and suggestive findings.

Energy Restriction in Animals Animals live longer and have fewer age-related diseases when their energy intakes are restricted. These life-prolonging benefits become evident when the diet provides enough food to prevent malnutrition and an energy intake of about 70 percent of normal. Exactly how energy restriction prolongs life remains largely unexplained, although gene activity appears to play a key role. The genetic activity of old mice differs from that of young mice, with some genes becoming more active with age and others less active. With an energy-restricted diet, many of the genetic activities of older mice revert to those of younger mice. These "slow-aging" genetic changes are apparent in as little as one month on an energy-restricted, but still nutritionally adequate, diet.

TABLE 16-1 Exercise Guidelines for Older Adults

	Endurance	Strength	Balance	Flexibility
Examples	© Geoff Manasse/ PhotoDisc/Jupiter Images	© IT Stock Free/Jupiter Images	© IT Stock Free/Jupiter Images	© Ron Chapple/ Thinkstock/Jupiter Images
Start easy	Be active 5 minutes on most or all days.	Using 0- to 2-pound weights, do 1 set of 8 repetitions twice a week.	Hold onto table or chair with one hand, then with one finger.	Hold stretch 10 seconds; do each stretch 3 times.
Progress gradually to goal	Be active 30 minutes (minimum) on most or all days.	Increase weight as able; do 2 sets of 8–15 repetitions twice a week.	Do not hold onto table or chair; then close eyes.	Hold stretch 30 seconds; do each stretch 5 times.
Cautions and comments	Stop if you are breathing so hard you can't talk or if you feel dizziness or chest pain.	Breathe out as you contract and in as you relax (do not hold breath); use smooth, steady movements.	Incorporate balance techniques with strength exercises as you progress.	Stretch after strength and endurance exercises for 20 minutes, 3 times a week; use slow, steady movements; bend joints slightly.

SOURCE: *Exercise: A Guide from the National Institute on Aging*, **www.nia.nih.gov**.

The consequences of energy restriction in animals include a delay in the onset, or prevention, of diseases such as atherosclerosis; prolonged growth and development; and improved blood glucose, insulin sensitivity, and blood lipids. In addition, energy metabolism slows and body temperature drops—indications of a reduced rate of oxygen consumption. As Highlight 11 explained, the use of oxygen during energy metabolism produces free radicals, which have been implicated in the aging process. Restricting energy intake in animals not only produces fewer free radicals, but also increases antioxidant activity and enhances DNA repair. Reducing oxidative stress may at least partially explain how restricting energy intake lengthens life expectancy.[9]

Interestingly, longevity appears to depend on restricting energy intake and not on the amount of body fat. Genetically obese rats live longer when given a restricted diet even though their body fat is similar to that of other rats allowed to eat freely.

Energy Restriction in Human Beings Research on a variety of animals ◆ confirms the relationship between energy restriction and longevity. Applying the results of animal studies to human beings is problematic, however, and conducting studies on human beings raises numerous questions—beginning with how to define energy restriction.[10] Does it mean eating less or just weighing less? Is it less than you want or less than the average? Does eating less have to result in weight loss? Does it matter whether weight loss results from more exercise or from less food? Or whether weight loss is intentional or unintentional? Answers await research.

◆ kCalorie-restricted research has been conducted on various species, including mice, rats, rhesus monkeys, cynomolgus monkeys, spiders, and fish.

Extreme starvation to extend life, like any extreme, is rarely, if ever, worth the price. Moderation, on the other hand, may be valuable. Many of the physiological responses to energy restriction seen in animals also occur in people whose intakes are *moderately* restricted. When people cut back on their usual energy intake by 10 to 20 percent, ◆ body weight, body fat, and blood pressure drop, and blood lipids and insulin response improve—favorable changes for preventing chronic diseases.[11] Some research suggests that fasting on alternative days may provide similar benefits.[12] The reduction in oxidative damage that occurs with energy restriction in animals also occurs in people whose diets include antioxidant nutrients and phytochemicals. Diets, such as the Mediterranean diet, which include an abundance of fruits, vegetables, olive oil, and red wine—with their array of antioxidants and phytochemicals—support good health and long life.[13] Clearly, nutritional adequacy is essential to living a long and healthy life.

◆ For perspective, a person with a usual energy intake of 2000 kcalories might cut back to 1600 to 1800 kcalories.

IN SUMMARY

Life expectancy in the United States increased dramatically in the 20th century. Factors that enhance longevity include limited or no alcohol use, regular balanced meals, weight control, adequate sleep, abstinence from smoking, and regular physical activity. Energy restriction in animals seems to lengthen their lives. Whether such dietary intervention in human beings is beneficial remains unknown. At the very least, nutrition—especially when combined with regular physical activity—can influence aging and longevity in human beings by supporting good health and preventing disease.

The Aging Process

As people get older, each person becomes less and less like anyone else. The older people are, the more time has elapsed for such factors as nutrition, genetics, physical activity, and everyday **stress** to influence physical and psychological aging.

stress: any threat to a person's well-being; a demand placed on the body to adapt.

stressors: environmental elements, physical or psychological, that cause stress.

Stress promotes the early onset of age-related diseases.[14] Both physical **stressors** (such as alcohol abuse, other drug abuse, smoking, pain, and illness) and

psychological stressors (such as exams, divorce, moving, and the death of a loved one) elicit the body's **stress response.** The body responds to such stressors with an elaborate series of physiological steps, as the nervous and hormonal systems bring about defensive readiness in every body part. These effects favor physical action—the classic fight-or-flight response. Prolonged or severe stress can drain the body of its reserves and leave it weakened, aged, and vulnerable to illness, especially if physical action is not taken. As people age, they lose their ability to adapt to both external and internal disturbances. When disease strikes, the reduced ability to adapt makes the aging individual more vulnerable to death than a younger person.

Because the stress response is mediated by hormones, it differs between men and women.[15] The fight-or-flight response may be more typical of men than of women. Women's reactions to stress more typically follow a pattern of "tend-and-befriend."[16] Women *tend* by nurturing and protecting themselves and their children. These actions promote safety and reduce stress. Women *befriend* by creating and maintaining a social group that can help in the process.

Highlight 11 described the oxidative stresses and cellular damage that occur when free radicals exceed the body's ability to defend itself. Increased free-radical activity and decreased antioxidant protection are common features of aging—and antioxidants seem to help slow the aging process.[17] Such findings seem to suggest that the fountain of youth may actually be a cornucopia of fruits and vegetables rich in antioxidants. (Return to Highlight 11 for more details on the antioxidant action of fruits and vegetables in defending against oxidative stress.)

Physiological Changes

As aging progresses, inevitable changes in each of the body's organs contribute to the body's declining function. These physiological changes influence nutrition status, just as growth and development do in the earlier stages of the life cycle.

Body Weight Two-thirds of older adults in the United States are now considered overweight or obese. Chapter 8 presented the many health problems that accompany obesity and the BMI guidelines for a healthy body weight (18.5 to 24.9). These guidelines apply to all adults, regardless of age, but they may be too restrictive for older adults. The importance of body weight in defending against chronic diseases differs for older adults. Being moderately *overweight* may not be harmful. For adults over 65, health risks do not become apparent until BMI reaches at least 27—and the relationship tends to diminish with age until it disappears by age 75. Older adults who are *obese,* however, face serious medical complications and can significantly improve their quality of life with weight loss.[18]

For some older adults, a low body weight may be more detrimental than a high one. Low body weight often reflects malnutrition and the trauma associated with a fall. Many older adults experience unintentional weight loss, in large part because of an inadequate food intake. Without adequate nutrient reserves, an underweight person may be unprepared to fight against diseases. For underweight people, even a slight weight loss (5 percent) increases the likelihood of disease and premature death, making every meal a life-saving event.

Body Composition In general, older people tend to lose bone and muscle and gain body fat. Many of these changes occur because some hormones that regulate appetite and metabolism become less active with age, whereas others become more active.*[19]

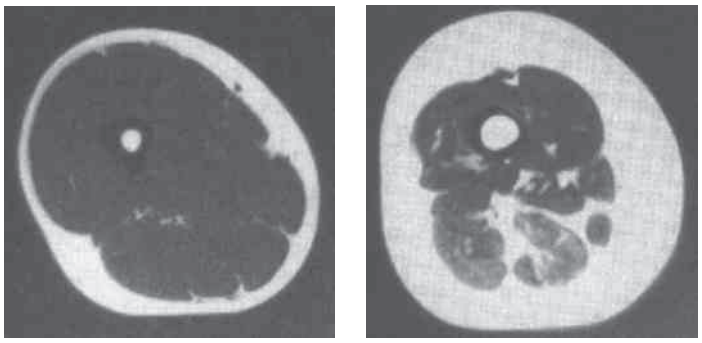
Loss of muscle, known as **sarcopenia,** can be significant in the later years, and its consequences can be quite dramatic (see Figure 16-2).[20] As muscles di-

stress response: the body's response to stress, mediated by both nerves and hormones.

sarcopenia (SAR-koh-PEE-nee-ah): loss of skeletal muscle mass, strength, and quality.
- **sarco** = flesh
- **penia** = loss or lack

* Causes of diminished appetite in older adults include increased cholecystokinin, leptin, and cytokines and decreased ghrelin and testosterone. Additional examples of hormones that change with age include growth hormone and androgens, which decline with advancing age, thus contributing to the decrease in lean body mass, and prolactin, which increases with age, helping to maintain body fat. Insulin sensitivity also diminishes as people grow older, most likely because of increases in body fat and decreases in physical activity.

FIGURE 16-2 Sarcopenia



Courtesy of Dr. William Evans (both)

These cross sections of two women's thighs may appear to be about the same size from the outside, but the 20-year-old woman's thigh (left) is dense with muscle tissue. The 64-year-old woman's thigh (right) has lost muscle and gained fat, changes that may be largely preventable with strength-building physical activities.

minish and weaken, people lose the ability to move and maintain balance—making falls likely. The limitations that accompany the loss of muscle mass and strength play a key role in the diminishing health that often accompanies aging.[21] Optimal nutrition and regular physical activity can help maintain muscle mass and strength and minimize the changes in body composition associated with aging.[22]

Risk factors for sarcopenia include weight loss, little physical activity, and cigarette smoking.[23] Obesity and the inflammation that accompanies it may also contribute to sarcopenia.[24]

Immune System Changes in the immune system also bring declining function with age. In addition, the immune system is compromised by nutrient deficiencies. Thus the combination of age and malnutrition makes older people vulnerable to infectious diseases. Adding insult to injury, antibiotics often are not effective against infections in people with compromised immune systems. Consequently, infectious diseases are a major cause of death in older adults. Older adults may improve their immune system responses by exercising regularly.

GI Tract In the GI tract, the intestinal wall loses strength and elasticity with age, and GI hormone secretions change. All of these actions slow motility. Constipation is much more common in the elderly than in the young. Changes in GI hormone secretions also diminish appetite, leading to decreased energy intake and weight loss.[25]

Atrophic gastritis, a condition that affects almost one-third of those over 60, is characterized ◆ by an inflamed stomach, bacterial overgrowth, and a lack of hydrochloric acid and intrinsic factor. All of these can impair the digestion and absorption of nutrients, most notably, vitamin B_{12}, but also biotin, folate, calcium, iron, and zinc.

◆ Consequences of atrophic gastritis:
- Inflamed stomach
- Increased bacterial growth
- Reduced hydrochloric acid
- Reduced intrinsic factor
- Increased risk of nutrient deficiencies, notably of vitamin B_{12}

Difficulty in swallowing, medically known as **dysphagia,** occurs in all age groups, but especially in the elderly. Being unable to swallow a mouthful of food can be scary, painful, and dangerous. Even swallowing liquids can be a problem for some people. Consequently, the person may eat less food and drink fewer beverages, resulting in weight loss, malnutrition, and dehydration. Dietary intervention for dysphagia is highly individualized based on the person's abilities and tolerances. The diet typically provides moist, soft-textured, tender-cooked, or pureed foods and thickened liquids.

dysphagia (dis-FAY-jah): difficulty in swallowing.

Tooth Loss Regular dental care over a lifetime protects against tooth loss and gum disease, which are common in old age. These conditions make chewing difficult or

◆ The medical term for lack of teeth is **edentulous** (ee-DENT-you-lus).
- **e** = without
- **dens** = teeth

painful. Dentures, even when they fit properly, are less effective than natural teeth, and inefficient chewing can cause choking. People with tooth loss, ◆ gum disease, and ill-fitting dentures tend to limit their food selections to soft foods. If foods such as corn on the cob, apples, and hard rolls are replaced by creamed corn, applesauce, and rice, then nutrition status may not be greatly affected. However, when food groups are eliminated and variety is limited, poor nutrition follows. People without teeth typically eat fewer fruits and vegetables and have less variety in their diets.[26] Consequently, they have low intakes of fiber and vitamins, which exacerbates their dental and overall health problems.[27] To determine whether a visit to the dentist is needed, an older adult can check the conditions listed in the margin. ◆

◆ Conditions requiring dental care:
Dry mouth
Eating difficulty
No dental care within two years
Tooth or mouth pain
Altered food selections
Lesions, sores, or lumps in mouth

Sensory Losses and Other Physical Problems Sensory losses and other physical problems can also interfere with an older person's ability to obtain adequate nourishment. Failing eyesight, for example, can make driving to the grocery store impossible and shopping for food a frustrating experience. It may become so difficult to read food labels and count money that the person doesn't buy needed foods. Carrying bags of groceries may be an unmanageable task. Similarly, a person with limited mobility may find cooking and cleaning up too hard to do. Not too surprisingly, the prevalence of undernutrition is high among those who are homebound.

Sensory losses can also interfere with a person's ability or willingness to eat. Taste and smell sensitivities tend to diminish with age and may make eating less enjoyable. If a person eats less, then weight loss and nutrient deficiencies may follow. Loss of vision and hearing may contribute to social isolation, and eating alone may lead to poor intake.

Other Changes

In addition to the physiological changes that accompany aging, adults change in many other ways that influence their nutrition status.[28] Psychological, economic, and social factors play big roles in a person's ability and willingness to eat.

Psychological Changes Although not an inevitable component of aging, depression is common among older adults.[29] Depressed people, even those without disabilities, lose their ability to perform simple physical tasks. They frequently lose their appetite and the motivation to cook or even to eat. An overwhelming sense of grief and sadness at the death of a spouse, friend, or family member may leave a person, especially an elderly person, feeling powerless to overcome depression. When a person is suffering the heartache and loneliness of bereavement, cooking meals may not seem worthwhile. The support and companionship of family and friends, especially at mealtimes, can help overcome depression and enhance appetite.

© Bob Thomas/Stone/Getty Images

Shared meals can brighten the day and enhance the appetite.

Economic Changes Overall, older adults today have higher incomes than their cohorts of previous generations. Still, 10 percent of the people over age 65 live in poverty. Factors such as living arrangements and income make significant differences in the food choices, eating habits, and nutrition status of older adults, especially those over age 80. People of low socioeconomic means are likely to have inadequate food and nutrient intakes. Only about one-third of the needy elderly receive assistance from federal programs.

Social Changes Malnutrition among older adults is most common in hospitals and nursing homes.[30] In the community, malnutrition is most likely to occur among those living alone, especially men; those with the least education; those living in federally funded housing (an indicator of low income); and those who have recently experienced a change in lifestyle. Adults who live alone do not necessarily make poor food choices, but they often consume too little food. Loneliness is directly related to nutritional inadequacies, especially of energy intake.

IN SUMMARY

Many changes that accompany aging can impair nutrition status. Among physiological changes, hormone activity alters body composition, immune system changes raise the risk of infections, atrophic gastritis interferes with digestion and absorption, and tooth loss limits food choices. Psychological changes such as depression, economic changes such as loss of income, and social changes such as loneliness contribute to poor food intake.

Energy and Nutrient Needs of Older Adults

© Kwame Zikomo/Super Stock

Growing old can be enjoyable for people who take care of their health and live each day fully.

Knowledge about the nutrient needs and nutrition status of older adults has grown considerably in recent years. The Dietary Reference Intakes (DRI) cluster people over 50 into two age categories—one group of 51 to 70 years and one of 71 and older. Increasingly, research is showing that the nutrition needs of people 50 to 70 years old differ from those of people over 70.

Setting standards for older people is difficult because individual differences become more pronounced as people grow older.[31] People start out with different genetic predispositions and ways of handling nutrients, and the effects of these differences become magnified with years of unique dietary habits. For example, one person may tend to omit fruits and vegetables from his diet, and by the time he is old, he may have a set of nutrition problems associated with a lack of fiber and antioxidants. Another person may have omitted milk and milk products all her life—her nutrition problems may be related to a lack of calcium. Also, as people age, they suffer different chronic diseases and take various medicines—both of which will affect nutrient needs. For all of these reasons, researchers have difficulty even defining "healthy aging," a prerequisite to developing recommendations to meet the "needs of practically all healthy persons." The following discussion gives special attention to the nutrients of greatest concern.

Water

Despite real fluid needs, many older people do not seem to feel thirsty or notice mouth dryness. Many nursing home employees say it is hard to persuade their elderly clients to drink enough water and fruit juices. Older adults may find it difficult and bothersome to get a drink or to get to a bathroom. Those who have lost bladder control may be afraid to drink too much water.

Dehydration is a risk for older adults.[32] Total body water decreases as people age, so even mild stresses such as fever or hot weather can precipitate rapid dehydration in older adults. Dehydrated older adults seem to be more susceptible to urinary tract infections, pneumonia, **pressure ulcers,** and confusion and disorientation. To prevent dehydration, older adults need to drink *at least* six glasses of water a day. ◆

◆ Beverage recommendation for adults 51+ yr:
- Men: 13 c/day
- Women: 9 c/day

Energy and Energy Nutrients

On average, energy needs decline an estimated 5 percent per decade. One reason is that people usually reduce their physical activity as they age, although they need not do so. Another reason is that basal metabolic rate declines 1 to 2 percent per decade in part because lean body mass and thyroid hormones diminish.[33]

The lower energy expenditure of older adults means that they need to eat less food to maintain their weights. Accordingly, the estimated energy requirements ◆ for adults decrease steadily after age 19, as the "How to" on p. 570 explains.

◆ When using the tables in Appendix F to estimate energy requirements:
- Men: Subtract 10 kcal/day for each year of age above 19
- Women: Subtract 7 kcal/day for each year of age above 19

pressure ulcers: damage to the skin and underlying tissues as a result of compression and poor circulation; commonly seen in people who are bedridden or chairbound.

HOW TO Estimate Energy Requirements for Older Adults

The "How to" on p. 257 described how to estimate the energy requirements for adults using an equation that accounts for age, physical activity, weight, and height. Alternatively, energy requirements for older adults can be "guesstimated" by using the values listed in the tables in Appendix F for adults 30 years of age and subtracting 7 kcalories for women and 10 kcalories for men per day for each year over 30.

For example, Table F-4 lists 2556 kcalories per day for a woman who is 5 feet 5 inches tall, weighs 150 pounds, and has a low activity level. To estimate the energy requirements of a similar 50-year-old woman, subtract 7 kcalories per day for each year over 30:

50 − 30 = 20 yr
20 yr × 7 kcal/day = 140 kcal/day
2556 kcal/day (at age 30) − 140 kcal/day
= 2416 kcal/day (at age 50)

Similarly, using Table F-5 to estimate the energy requirements of a sedentary 65-year-old man who is 5 feet 11 inches tall and weighs 250 pounds, subtract 10 kcalories per day for each year over 30:

65 − 30 = 35 yr
35 yr × 10 kcal/day = 350 kcal/day
3088 kcal/day (at age 30) − 350 kcal/day
= 2738 kcal/day (at age 65)

(Adults between the ages of 19 and 30 can also use the values listed in the tables in Appendix F by adding 7 kcalories for women and 10 kcalories for men per day for each year below 30.)

CENGAGENOW™
To practice estimating energy requirements for older adults, log on to **academic.cengage.com/login**, go to Chapter 16, then go to How To.

On limited energy allowances, people must select mostly nutrient-dense foods. There is little leeway for added sugars, solid fats, or alcohol. The USDA Food Guide (pp. 41–47) offers a dietary framework for adults of all ages.

Protein Because energy needs decrease, protein must be obtained from low-kcalorie sources of high-quality protein, such as lean meats, poultry, fish, and eggs; fat-free and low-fat milk products; and legumes. Protein is especially important for the elderly to support a healthy immune system, prevent muscle wasting, and optimize bone mass.

Underweight or malnourished older adults need protein- and energy-dense snacks such as hard-boiled eggs, tuna fish and crackers, peanut butter on wheat toast, and hearty soups. Drinking liquid nutritional formulas between meals can also boost energy and nutrient intakes.[34] Importantly, the diet should provide enjoyment as well as nutrients.[35]

Carbohydrate and Fiber As always, abundant carbohydrate is needed to protect protein from being used as an energy source. Sources of complex carbohydrates such as legumes, vegetables, whole grains, and fruits are also rich in fiber and essential vitamins and minerals. Average fiber intakes among older adults are lower than current recommendations (14 grams per 1000 kcalories).[36] Eating high-fiber foods and drinking water can alleviate constipation—a condition common among older adults, especially nursing home residents. Physical inactivity and medications also contribute to the high incidence of constipation.

Fat As is true for people of all ages, fat intake needs to be moderate in the diets of most older adults—enough to enhance flavors and provide valuable nutrients, but not so much as to raise the risks of cancer, atherosclerosis, and other degenerative diseases. This recommendation should not be taken too far; limiting fat too severely may lead to nutrient deficiencies and weight loss—two problems that carry greater health risks in the elderly than overweight.

Vitamins and Minerals

Most people can achieve adequate vitamin and mineral intakes simply by including foods from all food groups in their diets, but older adults often omit fruits and vegetables. Similarly, few older adults consume the recommended amounts of milk or milk products.

Vitamin B_{12} An estimated 10 to 30 percent of adults over 50 have atrophic gastritis. ◆ As Chapter 10 explained, people with atrophic gastritis are particularly vulnerable to vitamin B_{12} deficiency. The bacterial overgrowth that accompanies this condition uses up the vitamin, and without hydrochloric acid and intrinsic factor, digestion and absorption of vitamin B_{12} are inefficient. Given the poor cognition, anemia, and devastating neurological effects associated with a vitamin B_{12} defi-

◆ Reminder: *Atrophic gastritis* is a chronic inflammation of the stomach characterized by inadequate hydrochloric acid and intrinsic factor—two key players in vitamin B_{12} absorption.

ciency, an adequate intake is imperative.[37] The RDA for older adults is the same as for younger adults, but with the added suggestion to obtain most of a day's intake from vitamin B_{12}–fortified foods and supplements.[38] The bioavailability of vitamin B_{12} from these sources is better than from foods.

Dietary Guidelines for Americans 2005

People over age 50 should consume vitamin B_{12} from fortified foods or supplements.

Vitamin D Vitamin D deficiency is a problem among older adults. Only vitamin D–fortified milk provides significant vitamin D, and many older adults drink little or no milk. Further compromising the vitamin D status of many older people, especially those in nursing homes, is their limited exposure to sunlight. Finally, aging reduces the skin's capacity to make vitamin D and the kidneys' ability to convert it to its active form. Not only are older adults not getting enough vitamin D, but they may actually need more to improve both muscle and bone strength.[39] To prevent bone loss and to maintain vitamin D status, especially in those who engage in minimal outdoor activity, adults 51 to 70 years old need 10 micrograms daily, and those over 70 need 15 micrograms.[40]

Dietary Guidelines for Americans 2005

Older adults should consume extra vitamin D from vitamin D–fortified foods and/or supplements.

Calcium Both Chapter 12 and Highlight 12 emphasized the importance of abundant dietary calcium throughout life, especially for women after menopause, to protect against osteoporosis. The DRI Committee recommends 1200 milligrams of calcium daily, but the calcium intakes of older people in the United States are well below recommendations.[41] Some older adults avoid milk and milk products because they dislike these foods or associate them with stomach discomfort. Simple solutions include using calcium-fortified juices, adding powdered milk to recipes, and taking supplements. Chapter 12 offered many other strategies for including nonmilk sources of calcium for those who do not drink milk.

Iron The iron needs of men remain unchanged throughout adulthood. For women, iron needs decrease substantially when blood loss through menstruation ceases. Consequently, iron-deficiency anemia is less common in older adults than in younger people. In fact, elevated iron stores are more likely than deficiency in older people, especially those who take iron supplements, eat red meat regularly, and include vitamin C–rich fruits in their daily diet.[42]

Nevertheless, iron deficiency may develop in older adults, especially when their food energy intakes are low. Aside from diet, two other factors may lead to iron deficiency in older people: chronic blood loss from diseases and medicines and poor iron absorption due to reduced stomach acid secretion and antacid use. Iron deficiency impairs immunity and leaves older adults vulnerable to infectious diseases.[43] Anyone concerned with older people's nutrition should keep these possibilities in mind.

Taking time to nourish your body well is a gift you give yourself.

Nutrient Supplements

People judge for themselves how to manage their nutrition, and more than half of older adults turn to dietary supplements.[44] When recommended by a physician or

registered dietitian, vitamin D and calcium supplements for osteoporosis or vitamin B_{12} for pernicious anemia may be beneficial. Many health care professionals recommend a daily multivitamin-mineral supplement that provides 100 percent or less of the Daily Value for the listed nutrients.[45] They reason that such a supplement is more likely to be beneficial than to cause harm.

People with small energy allowances would do well to become more active so they can afford to eat more food. Food is the best source of nutrients for everybody. Supplements are just that—supplements to foods, not substitutes for them. For anyone who is motivated to obtain the best possible health, it is never too late to learn to eat well, drink water, exercise regularly, and adopt other lifestyle habits such as quitting smoking and moderating alcohol use.

IN SUMMARY

The table below summarizes the nutrient concerns of aging. Although some nutrients need special attention in the diet, supplements are not routinely recommended. The ever-growing number of older people creates an urgent need to learn more about how their nutrient requirements differ from those of others and how such knowledge can enhance their health.

Nutrient	Effect of Aging	Comments
Water	Lack of thirst and decreased total body water make dehydration likely.	Mild dehydration is a common cause of confusion. Difficulty obtaining water or getting to the bathroom may compound the problem.
Energy	Need decreases as muscle mass decreases (sarcopenia).	Physical activity moderates the decline.
Fiber	Likelihood of constipation increases with low intakes and changes in the GI tract.	Inadequate water intakes and lack of physical activity, along with some medications, compound the problem.
Protein	Needs may stay the same or increase slightly.	Low-fat, high-fiber legumes and grains meet both protein and other nutrient needs.
Vitamin B_{12}	Atrophic gastritis is common.	Deficiency causes neurological damage; supplements may be needed.
Vitamin D	Increased likelihood of inadequate intake; skin synthesis declines.	Daily sunlight exposure in moderation or supplements may be beneficial.
Calcium	Intakes may be low; osteoporosis is common.	Stomach discomfort commonly limits milk intake; calcium substitutes or supplements may be needed.
Iron	In women, status improves after menopause; deficiencies are linked to chronic blood losses and low stomach acid output.	Adequate stomach acid is required for absorption; antacid or other medicine use may aggravate iron deficiency; vitamin C and meat increase absorption.

Nutrition-Related Concerns of Older Adults

Nutrition may play a greater role than has been realized in preventing many changes once thought to be inevitable consequences of growing older. The following discussions of vision, arthritis, and the aging brain show that nutrition may provide at least some protection against some of the conditions associated with aging.

Vision

One key aspect of healthy aging is maintaining good vision.[46] Age-related eye diseases that impair vision, such as cataract and macular degeneration, correlate with poor survival that cannot be explained by other risk factors.[47] Following a healthy diet as described by the *Dietary Guidelines for Americans* is one way to protect against these age-related vision problems.[48]

cataracts (KAT-ah-rakts): thickenings of the eye lenses that impair vision and can lead to blindness.

Cataracts **Cataracts** are age-related thickenings in the lenses of the eyes that impair vision. If not surgically removed, they ultimately lead to blindness. Cataracts

occur even in well-nourished individuals as a result of ultraviolet light exposure, oxidative stress, injury, viral infections, toxic substances, and genetic disorders. Many cataracts, however, are vaguely called senile cataracts—meaning "caused by aging." In the United States, more than half of all adults 65 and older have a cataract.

Oxidative stress appears to play a significant role in the development of cataracts, and the antioxidant nutrients may help minimize the damage. Studies have reported an inverse relationship between cataracts and dietary intakes of vitamin C, vitamin E, and carotenoids; taking supplements or eating fruits and vegetables rich in these antioxidant nutrients seems to slow the progression or reduce the risk of developing cataracts.[49]

One other diet-related factor may play a role in the development of cataracts—obesity.[50] Obesity appears to be associated with cataracts, but its role has not been identified. Risk factors that typically accompany overweight, such as inactivity, diabetes, or hypertension, do not explain the association.

Macular Degeneration The leading cause of visual loss among older people is age-related **macular degeneration,** a deterioration of the macular region of the retina.[51] As with cataracts, risk factors for age-related macular degeneration include oxidative stress from sunlight, and preventive factors may include supplements of antioxidant vitamins plus zinc and the carotenoids lutein and zeaxanthin.[52] Total dietary fat may also be a risk factor for macular degeneration, but the omega-3 fatty acids of fish may be protective.

Arthritis

More than 40 million people in the United States have some form of **arthritis.** As the population ages, it is expected that the prevalence will increase to 60 million by 2020.

Osteoarthritis The most common type of arthritis that disables older people is **osteoarthritis,** a painful deterioration of the cartilage in the joints. During movement, the ends of bones are normally protected from wear by cartilage and by small sacs of fluid that act as a lubricant. With age, the cartilage sometimes disintegrates, and the joints become malformed and painful to move.

One known connection between osteoarthritis ◆ and nutrition is overweight. Weight loss may relieve some of the pain for overweight persons with osteoarthritis, partly because the joints affected are often weight-bearing joints that are stressed and irritated by having to carry excess pounds. Interestingly, though, weight loss often relieves much of the pain of arthritis in the hands as well, even though they are not weight-bearing joints. Jogging and other weight-bearing exercises do not worsen arthritis. In fact, both aerobic activity and strength training offer improvements in physical performance and pain relief, especially when accompanied by even modest weight loss.[53]

◆ Risk factors for osteoarthritis:
- Age
- Smoking
- High BMI at age 40
- Lack of hormone therapy (in women)

Rheumatoid Arthritis Another type of arthritis known as **rheumatoid arthritis** has possible links to diet through the immune system.[54] In rheumatoid arthritis, the immune system mistakenly attacks the bone coverings as if they were made of foreign tissue. In some individuals, certain foods, notably vegetables and olive oil, may moderate the inflammatory response and provide some relief.[55]

The omega-3 fatty acids commonly found in fish oil reduce joint tenderness and improve mobility in some people with rheumatoid arthritis.[56] The same diet recommended for heart health—one low in saturated fat from meats and milk products and high in omega-3 fats from fish—helps prevent or reduce the inflammation in the joints that makes arthritis so painful.

Another possible link between nutrition and rheumatoid arthritis involves the oxidative damage to the membranes within joints that causes inflammation and swelling. The antioxidant vitamins C and E and the carotenoids defend against oxidation, and increased intakes of these nutrients may help prevent or relieve the pain of rheumatoid arthritis.[57]

macular (MACK-you-lar) **degeneration:** deterioration of the macular area of the eye that can lead to loss of central vision and eventual blindness. The **macula** is a small, oval, yellowish region in the center of the retina that provides the sharp, straight-ahead vision so critical to reading and driving.

arthritis: inflammation of a joint, usually accompanied by pain, swelling, and structural changes.

osteoarthritis: a painful, degenerative disease of the joints that occurs when the cartilage in a joint deteriorates; joint structure is damaged, with loss of function; also called **degenerative arthritis.**

rheumatoid (ROO-ma-toyd) **arthritis:** a disease of the immune system involving painful inflammation of the joints and related structures.

Gout Another form of arthritis, which most commonly affects men, is **gout,** a condition characterized by deposits of uric acid crystals in the joints. Uric acid derives from the breakdown of **purines,** primarily from those made by the body but also from those found in foods.[58] Foods such as meat and seafood that are rich in purines increase uric acid levels and the risk of gout, whereas milk products seem to lower uric acid levels and the risk of gout.[59]

Treatment Treatment for arthritis—dietary or otherwise—may help relieve discomfort and improve mobility, but it does not cure the condition. Traditional medical intervention for arthritis includes medication and surgery. Alternative therapies to treat arthritis abound, but none have proved safe and effective in scientific studies. Popular supplements—glucosamine, chondroitin, or a combination—may relieve pain and improve mobility as well as over-the-counter pain relievers, but mixed reports from studies emphasize the need for additional research.[60] The regular use of drugs and supplements can impose nutrition risks; many affect appetite and alter the body's use of nutrients, as Chapter 19 explains.

TABLE 16-2 Summary of Nutrient-Brain Relationships

Brain Function	Depends on an Adequate Intake of:
Short-term memory	Vitamin B_{12}, vitamin C, vitamin E
Performance in problem-solving tests	Riboflavin, folate, vitamin B_{12}, vitamin C
Mental health	Thiamin, niacin, zinc, folate
Cognition	Folate, vitamin B_6, vitamin B_{12}, iron, vitamin E
Vision	Essential fatty acids, vitamin A
Neurotransmitter synthesis	Tyrosine, tryptophan, choline

gout (GOWT): a common form of arthritis characterized by deposits of uric acid crystals in the joints.

purines: compounds of nitrogen-containing bases such as adenine, guanine, and caffeine. Purines that originate from the body are *endogenous* and those that derive from foods are *exogenous.*

neurons: nerve cells; the structural and functional units of the nervous system. Neurons initiate and conduct nerve impulse transmissions.

senile dementia: the loss of brain function beyond the normal loss of physical adeptness and memory that occurs with aging.

Alzheimer's disease: a degenerative disease of the brain involving memory loss and major structural changes in neuron networks; also known as *senile dementia of the Alzheimer's type (SDAT), primary degenerative dementia of senile onset,* or *chronic brain syndrome.*

The Aging Brain

The brain, like all of the body's organs, responds to both genetic and environmental factors that can enhance or diminish its amazing capacities. One of the challenges researchers face when studying the human brain is to distinguish among normal age-related physiological changes, changes caused by diseases, and changes that result from cumulative, environmental factors such as diet.

The brain normally changes in some characteristic ways as it ages. For one thing, its blood supply decreases. For another, the number of **neurons,** the brain cells that specialize in transmitting information, diminishes as people age. When the number of nerve cells in one part of the cerebral cortex diminishes, hearing and speech are affected. Losses of neurons in other parts of the cortex can impair memory and cognitive function. When the number of neurons in the hindbrain diminishes, balance and posture are affected. Losses of neurons in other parts of the brain affect still other functions. Some of the cognitive loss and forgetfulness generally attributed to aging may be due in part to environmental, and therefore controllable, factors—including nutrient deficiencies.

Nutrient Deficiencies and Brain Function Nutrients influence the development and activities of the brain. The ability of neurons to synthesize specific neurotransmitters depends in part on the availability of precursor nutrients that are obtained from the diet.[61] The neurotransmitter serotonin, for example, derives from the amino acid tryptophan. To function properly, the enzymes involved in neurotransmitter synthesis require vitamins and minerals. Thus nutrient deficiencies may contribute to the loss of memory and cognition that some older adults experience. Such losses may be preventable or at least diminished or delayed through diet and exercise.[62] Table 16-2 summarizes some of the better-known connections between brain function and nutrients.

In some instances, the degree of cognitive loss is extensive. Such **senile dementia** may be attributable to a specific disorder such as a brain tumor or Alzheimer's disease. Table 16-3 lists common signs of dementia.

Alzheimer's Disease Much attention has focused on the *abnormal* deterioration of the brain called **Alzheimer's disease,** which affects 10 percent of U.S. adults by age 65 and 30 percent of those over 85. Diagnosis of Alzheimer's disease depends on its characteristic symptoms: the victim gradually loses memory and reasoning, the ability to communicate, physical capabilities, and eventually life itself.[63] Nerve cells in the brain die, and communication between the cells breaks down.

Researchers are closing in on the exact cause of Alzheimer's disease.* Clearly, genetic factors are involved.[64] Free radicals and oxidative stress also seem to be in-

*A report on the genetic and other aspects of Alzheimer's is available from Alzheimer's Disease Education and Referral Center, P.O. Box 8250, Silver Springs, MD 20907-8250.

volved.[65] Nerve cells in the brains of people with Alzheimer's disease show evidence of free-radical attack—damage to DNA, cell membranes, and proteins. They also show evidence of the minerals that trigger free-radical attacks—iron, copper, zinc, and aluminum. Some research suggests that the antioxidant nutrients can limit free-radical damage and delay or prevent Alzheimer's disease.[66]

In Alzheimer's disease, the brain develops **senile plaques** and **neurofibrillary tangles.** Senile plaques are clumps of a protein fragment called beta-amyloid, whereas neurofibrillary tangles are snarls of the fibers that extend from the nerve cells. Both seem to occur in response to oxidative stress.[67] Researchers question whether these characteristics are the cause or the result of Alzheimer's disease.[68] In fact, scientists are unsure whether these plaques and tangles are causing the damage, serving as markers, or even protecting by sequestering the proteins that begin the dementia process.[69]

Late in the course of the disease there is a decline in the activity of the enzyme that assists in the production of the neurotransmitter acetylcholine from choline and acetyl CoA. Acetylcholine is essential to memory, but supplements of choline (or of lecithin, which contains choline) have no effect on memory or on the progression of the disease. Drugs that inhibit the breakdown of acetylcholine, on the other hand, have proved beneficial.

Research suggests that cardiovascular disease risk factors such as high blood pressure, diabetes, and elevated levels of homocysteine may be related to the development of Alzheimer's disease.[70] Diets designed to support a healthy heart, including omega-3 fatty acids and light-to-moderate alcohol intake, may benefit a healthy brain as well.[71]

Treatment for Alzheimer's disease involves providing care to clients and support to their families. Drugs are used to improve or at least to slow the loss of short-term memory and cognition, but they do not cure the disease. Other drugs may be used to control depression, anxiety, and behavior problems.

Maintaining appropriate body weight may be the most important nutrition concern for the person with Alzheimer's disease. Depression and forgetfulness can lead to changes in eating behaviors and poor food intake. Furthermore, changes in the body's weight-regulation system may contribute to weight loss. Perhaps the best that a caregiver can do nutritionally for a person with Alzheimer's disease is to supervise food planning and mealtimes. Providing well-liked and well-balanced meals and snacks in a cheerful atmosphere encourages food consumption. To minimize confusion, offer a few ready-to-eat foods, in bite-size pieces, with seasonings and sauces. To avoid mealtime disruptions, control distractions such as music, television, children, and the telephone.

TABLE 16-3 Common Signs of Dementia

- Agitated behavior
- Becoming lost in familiar surroundings or circumstances
- Confusion
- Delusions
- Loss of interest in daily activities
- Loss of memory
- Loss of problem-solving skills
- Unclear thinking

© Deborah Davis/PhotoEdit

Both foods and mental challenges nourish the brain.

IN SUMMARY

Senile dementia and other losses of brain function afflict millions of older adults, and others face loss of vision due to cataracts or macular degeneration or cope with the pain of arthritis. As the number of people over age 65 continues to grow, the need for solutions to these problems becomes urgent. Some problems may be inevitable, but others are preventable and good nutrition may play a key role.

Food Choices and Eating Habits of Older Adults

Older people are an incredibly diverse group, and for the most part, they are independent, socially sophisticated, mentally lucid, fully participating members of society who report themselves to be happy and healthy. In fact, the quality of life

senile plaques: clumps of the protein fragment beta-amyloid on the nerve cells, commonly found in the brains of people with Alzheimer's dementia.

neurofibrillary tangles: snarls of the threadlike strands that extend from the nerve cells, commonly found in the brains of people with Alzheimer's dementia.

among the elderly has improved, and their chronic disabilities have declined dramatically in recent years.[72] By practicing stress-management skills, maintaining physical fitness, participating in activities of interest, and cultivating spiritual health, as well as obtaining adequate nourishment, people can support a high quality of life into old age (see Table 16-4 for some strategies).

Older people spend more money per person on foods to eat at home than other age groups and less money on foods away from home. Manufacturers would be wise to cater to the preferences of older adults by providing good-tasting, nutritious foods in easy-to-open, single-serving packages with labels that are easy to read. Such services enable older adults to maintain their independence and to feel a sense of control and involvement in their own lives. Another way older adults can take care of themselves is by remaining or becoming physically active. As mentioned earlier, physical activity helps preserve one's ability to perform daily tasks and so promotes independence.

Familiarity, taste, and health beliefs are most influential on older people's food choices. Eating foods that are familiar, especially ethnic foods that recall family meals and pleasant times, can be comforting. People 65 and over are less likely to diet to lose weight than younger people are, but they are more likely to diet in pursuit of medical goals such as controlling blood glucose and cholesterol.

Food Assistance Programs

The Nutrition Screening Initiative is part of a national effort to identify and treat nutrition problems in older persons; it uses a screening checklist. To *determine* the risk of malnutrition in older clients, health care professionals can keep in mind the characteristics and questions listed in Table 16-5.

An integral component of the Older Americans Act (OAA) is the OAA Nutrition Program, formerly known as the Elderly Nutrition Program. Its services are designed to improve older people's nutrition status and enable them to avoid medical problems, continue living in communities of their own choice, and stay out of institutions. Its specific goals are to provide low-cost, nutritious meals; opportunities for social interaction; homemaker education and shopping assistance; counseling and referral to social services; and transportation. The program's mission has always been to provide "more than a meal."

TABLE 16-4 Strategies for Growing Old Healthfully

- Choose nutrient-dense foods.
- Be physically active. Walk, run, dance, swim, bike, or row for aerobic activity. Lift weights, do calisthenics, or pursue some other activity to tone, firm, and strengthen muscles. Practice balancing on one foot or doing simple movements with your eyes closed. Modify activities to suit changing abilities and tastes.
- Maintain appropriate body weight.
- Reduce stress (cultivate self-esteem, maintain a positive attitude, manage time wisely, know your limits, practice assertiveness, release tension, and take action).
- For women, discuss with a physician the risks and benefits of estrogen replacement therapy.
- For people who smoke, discuss with a physician strategies and programs to help you quit.
- Expect to enjoy sex, and learn new ways of enhancing it.
- Use alcohol only moderately, if at all; use drugs only as prescribed.
- Take care to prevent accidents.
- Expect good vision and hearing throughout life; obtain glasses and hearing aids if necessary.
- Take care of your teeth; obtain dentures if necessary.
- Be alert to confusion as a disease symptom, and seek diagnosis.
- Take medications as prescribed; see a physician before self-prescribing medicines or herbal remedies and a registered dietitian before self-prescribing supplements.
- Control depression through activities and friendships; seek professional help if necessary.
- Drink 6 to 8 glasses of water every day.
- Practice mental skills. Keep on solving math problems and crossword puzzles, playing cards or other games, reading, writing, imagining, and creating.
- Make financial plans early to ensure security.
- Accept change. Work at recovering from losses; make new friends.
- Cultivate spiritual health. Cherish personal values. Make life meaningful.
- Go outside for sunshine and fresh air as often as possible.
- Be socially active—play bridge, join an exercise or dance group, take a class, teach a class, eat with friends, volunteer time to help others.
- Stay interested in life—pursue a hobby, spend time with grandchildren, take a trip, read, grow a garden, or go to the movies.
- Enjoy life.

TABLE 16-5 Risk Factors for Malnutrition in Older Adults

	These questions help *determine* the risk of malnutrition in older adults:
Disease	• Do you have an illness or condition that changes the types or amounts of foods you eat?
Eating poorly	• Do you eat fewer than two meals a day? Do you eat fruits, vegetables, and milk products daily?
Tooth loss or mouth pain	• Is it difficult or painful to eat?
Economic hardship	• Do you have enough money to buy the food you need?
Reduced social contact	• Do you eat alone most of the time?
Multiple medications	• Do you take three or more different prescribed or over-the-counter medications daily?
Involuntary weight loss or gain	• Have you lost or gained 10 pounds or more in the last six months?
Needs assistance	• Are you physically able to shop, cook, and feed yourself?
Elderly person	• Are you older than 80?

© Jeff Greenberg/PhotoEdit

Social interactions at a congregate meal site can be as nourishing as the foods served.

The OAA Nutrition Program provides for **congregate meals** at group settings such as community centers. Administrators try to select sites for congregate meals where as many eligible people as possible can participate. Volunteers may also deliver meals to those who are homebound either permanently or temporarily; these home-delivered meals are known as **Meals on Wheels.** Although the home-delivery program ensures nutrition, its recipients miss out on the social benefits of the congregate meals. Therefore, every effort is made to persuade older people to come to the shared meals, if they can. All persons aged 60 years and older and their spouses are eligible to receive meals from these programs, regardless of their income. Priority is given to those who are economically and socially needy. An estimated 3 million of our nation's older adults benefit from these meals.

These programs provide at least one meal a day that meets a third of the RDA for this age group, and they must operate five or more days a week. Many programs voluntarily offer additional services designed to appeal to older adults: provisions for special diets (to meet medical needs or religious preferences), food pantries, ethnic meals, and delivery of meals to the homeless. Adding breakfast to the service increases energy and nutrient intakes, which helps to relieve hunger and depression.[73]

Older adults can also take advantage of the Senior Farmers Market Nutrition Program, which provides low-income older adults with coupons that can be exchanged for fresh fruits, vegetables, and herbs at community-supported farmers' markets and roadside stands. This program increases fresh fruit and vegetable consumption, provides nutrition information, and even reaches the homebound elderly, a group of people who normally do not have access to farmers' markets.

Older adults can learn about the available programs in their communities by looking in the Yellow Pages of the telephone book under "Social Services" or "Senior Citizens' Organizations."* In addition, the local senior center and hospital can usually direct people to programs that provide nutrition and other health-related services.

Meals for Singles

Many older adults live alone, and singles of all ages face challenges in purchasing, storing, and preparing food. Large packages of meat and vegetables are often intended for families of four or more, and even a head of lettuce can spoil before one

congregate meals: nutrition programs that provide food for the elderly in conveniently located settings such as community centers.

Meals on Wheels: a nutrition program that delivers food for the elderly to their homes.

* To find a local provider, call Eldercare Locator at (800) 677-1116.

person can use it all. Many singles live in small dwellings and have little storage space for foods. A limited income presents additional obstacles. This section offers suggestions that can help to solve some of the problems singles face, beginning with a special note about the dangers of foodborne illness.

Foodborne Illness The risk of older adults getting a foodborne illness is greater than for other adults. The consequences of an upset stomach, diarrhea, fever, vomiting, abdominal cramps, and dehydration are oftentimes more severe, sometimes leading to paralysis, meningitis, or even death. For these reasons, older adults need to carefully follow the food safety suggestions presented in Highlight 18.

Dietary Guidelines for Americans 2005

- Older adults should not eat or drink unpasteurized milk, milk products, or juices; raw or undercooked eggs, meat, poultry, fish, or shellfish; or raw sprouts.
- Older adults should only eat certain deli meats and frankfurters that have been reheated to steaming hot.

Spend Wisely People who have the means to shop and cook for themselves can cut their food bills simply by being wise shoppers. Large supermarkets are usually less expensive than convenience stores. A grocery list helps reduce impulse buying, and specials and coupons can save money when the items featured are those that the shopper needs and uses.

Buying the right amount so as not to waste any food is a challenge for people eating alone. They can buy fresh milk in the size best suited for personal needs. Pint-size and even cup-size boxes ◆ of milk are available and can be stored unopened on a shelf for as long as three months without refrigeration.

◆ Boxes of milk that can be stored at room temperature have been exposed to temperatures above those of pasteurization just long enough to sterilize the milk—a process called **ultrahigh temperature (UHT).**

Many foods that offer a variety of nutrients for practically pennies have a long shelf life; staples such as rice, pastas, dry powdered milk, and dried legumes can be purchased in bulk and stored for months at room temperature. Other foods that are usually a good buy include whole pieces of cheese rather than sliced or shredded cheese, fresh produce in season, variety meats such as chicken livers, and cereals that require cooking instead of ready-to-serve cereals.

A person who has ample freezer space can buy large packages of meat, such as pork chops, ground beef, or chicken, when they are on sale. Then the meat can be immediately wrapped into individual servings for the freezer. All the individual servings can be put in a bag marked appropriately with the contents and the date.

Frozen vegetables are more economical in large bags than in small boxes. After the amount needed is taken out, the bag can be closed tightly with a twist tie or rubber band. If the package is returned quickly to the freezer each time, the vegetables will stay fresh for a long time.

Finally, breads and cereals usually must be purchased in larger quantities. Again the amount needed for a few days can be taken out and the rest stored in the freezer.

Grocers will break open a package of wrapped meat and rewrap the portion needed. Similarly, eggs can be purchased by the half-dozen. Eggs do keep for long periods, though, if stored properly in the refrigerator.

Fresh fruits and vegetables can be purchased individually. A person can buy fresh fruit at various stages of ripeness: a ripe one to eat right away, a semiripe one to eat soon after, and a green one to ripen on the windowsill. If vegetables are packaged in large quantities, the grocer can break open the package so that a smaller amount can be purchased. Small cans of fruits and vegetables, even though they are more expensive per unit, are a reasonable alternative, considering that it is expensive to buy a regular-size can and let the unused portion spoil.

© Lonnie Duka/Index Stock Imagery

Buy only what you will use.

Be Creative Creative chefs think of various ways to use foods when only large amounts are available. For example, a head of cauliflower can be divided into

thirds. Then one-third is cooked and eaten hot. Another third is put into a vinegar and oil marinade for use in a salad. And the last third can be used in a casserole or stew.

A variety of vegetables and meats can be enjoyed stir-fried; inexpensive vegetables such as cabbage, celery, and onion are delicious when crisp cooked in a little oil with herbs or lemon added. Interesting frozen vegetable mixtures are available in larger grocery stores. Cooked, leftover vegetables can be dropped in at the last minute. A bonus of a stir-fried meal is that there is only one pan to wash. Similarly, a microwave oven allows a chef to use fewer pots and pans. Meals and leftovers can also be frozen or refrigerated in microwavable containers to reheat as needed.

Many frozen dinners offer nutritious options. Adding a fresh salad, a whole-wheat roll, and a glass of milk can make a nutritionally balanced meal.

Also, single people shouldn't hesitate to invite someone to share meals with them whenever there is enough food. It's likely that the person will return the invitation, and both parties will get to enjoy companionship and a meal prepared by others.

© Masterfile

Invite guests to share a meal.

IN SUMMARY

Older people can benefit from both the nutrients provided and the social interaction available at congregate meals. Other government programs deliver meals to those who are homebound. With creativity and careful shopping, those living alone can prepare nutritious, inexpensive meals. Physical activity, mental challenges, stress management, and social activities can also help people grow old comfortably.

Nutrition Portfolio

By eating a balanced diet, maintaining a healthy body weight, and engaging in a variety of physical, social, and mental activities, you can enjoy good health in later life.

- Visit older adults in your community and consider whether they have the financial means, physical ability, and social support they need to eat adequately.
- Note whether they have experienced an unintentional loss of weight recently.
- Discuss how they occupy their time physically, socially, and mentally.

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log onto **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. What roles does nutrition play in aging, and what roles can it play in retarding aging? (pp. 562–565)
2. What are some of the physiological changes that occur in the body's systems with aging? To what extent can aging be prevented? (pp. 565–568)
3. Why does the risk of dehydration increase as people age? (p. 569)
4. Why do energy needs usually decline with advancing age? (p. 569)
5. Which vitamins and minerals need special consideration for the elderly? Explain why. Identify some factors that complicate the task of setting nutrient standards for older adults. (pp. 570–571)
6. Discuss the relationships between nutrition and cataracts and between nutrition and arthritis. (pp. 572–574)
7. What characteristics contribute to malnutrition in older people? (pp. 568–569, 575–577)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 582.

1. Life expectancy in the United States is about:
   a. 48 to 60 years.
   b. 58 to 70 years.
   c. 68 to 80 years.
   d. 78 to 90 years.
2. The human life span is about:
   a. 85 years.
   b. 100 years.
   c. 115 years.
   d. 130 years.
3. A 72-year-old person whose physical health is similar to that of people 10 years younger has a(n):
   a. chronological age of 62.
   b. physiological age of 72.
   c. physiological age of 62.
   d. absolute age of minus 10.
4. Rats live longest when given diets that:
   a. eliminate all fat.
   b. provide lots of protein.
   c. allow them to eat freely.
   d. restrict their energy intakes.
5. Which characteristic is *not* commonly associated with atrophic gastritis?
   a. inflamed stomach
   b. vitamin B_{12} toxicity
   c. bacterial overgrowth
   d. lack of intrinsic factor
6. On average, adult energy needs:
   a. decline 5 percent per year.
   b. decline 5 percent per decade.
   c. remain stable throughout life.
   d. rise gradually throughout life.
7. Which nutrients seem to protect against cataract development?
   a. minerals
   b. lecithins
   c. antioxidants
   d. amino acids
8. The best dietary advice for a person with osteoarthritis might be to:
   a. avoid milk products.
   b. take fish oil supplements.
   c. take vitamin E supplements.
   d. lose weight, if overweight.
9. Congregate meal programs are preferable to Meals on Wheels because they provide:
   a. nutritious meals.
   b. referral services.
   c. social interactions.
   d. financial assistance.
10. The Elderly Nutrition Program is available to:
    a. all people 65 years and older.
    b. all people 60 years and older.
    c. homebound people only, 60 years and older.
    d. low-income people only, 60 years and older..

Hunger and Community Nutrition

© David Woods/CORBIS

One person in every eight worldwide experiences persistent hunger—not the healthy appetite triggered by anticipation of a hearty meal but the painful sensation caused by a lack of food. The physical feelings are the same, but the hunger described in this highlight takes on greater meaning because the lack of food is recurrent and involuntary. Hunger deprives a person of the physical and mental energy needed to enjoy a full life and often leads to severe malnutrition and death. Tens of thousands of people—one child every five seconds—die of starvation each day.[1]

Resolving the hunger problem may seem at first beyond the influence of the ordinary person. Can one person's choice to volunteer at a food recovery program make a difference? In truth, such choices do produce several benefits. For one, a person's action may influence many other people over time. For another, an action repeated becomes a habit, with compounded benefits. For still another, making choices with an awareness of the consequences gives a person a sense of personal control, hope, and effectiveness. The daily actions of many concerned people can help solve the problems of hunger in their own neighborhoods or on the other side of the world.

Hunger in the United States

Ideally, all people at all times would have access to enough food to support an active, healthy life; in other words, they would experience **food security.** Unfortunately, over 38 million people in the United States, including 14 million children, live in poverty and cannot afford to buy enough food to maintain good health.[2] Said another way, one out of ten households experiences hunger or the threat of hunger. Given the agricultural bounty and enormous wealth in this country, do these numbers surprise you? The limited or uncertain availability of nutritionally adequate and safe foods is known as **food insecurity** and is a major social problem in our nation today. Inadequate diets lead to poor health in adults and impaired physical, psychological, and cognitive development in children.

The accompanying "How to" (p. 584) presents the questions used in national surveys to identify food insecurity in the United States, and Figure H16-1 shows the most recent findings. Responses to these questions provide crude, but necessary, data to estimate the degree of hunger in this country.[3]

Defining Hunger in the United States

At its most extreme, people experience hunger because they have absolutely no food. More often, they have too little food **(food insufficiency)** and try to stretch their limited resources by eating small meals or skipping meals—often for days at a time. Sometimes hungry people obtain enough food to satisfy their hunger, perhaps by seeking food assistance or finding food through socially unacceptable ways—begging from strangers, stealing from markets, or scavenging through garbage cans, for example. Sometimes obtaining food raises concerns for food safety—for example, when rot, slime, mold, or insects have damaged foods or when people eat others' leftovers or meat from roadkill.[4]

Hunger has many causes, but in developed countries, the primary cause is **food poverty.** People are hungry not because there is no food nearby to purchase but because they lack

GLOSSARY

emergency shelters: facilities that are used to provide temporary housing.

food bank: a facility that collects and distributes food donations to authorized organizations feeding the hungry.

food insecurity: limited or uncertain access to foods of sufficient quality or quantity to sustain a healthy and active life.

food insufficiency: an inadequate amount of food due to a lack of resources.

food pantries: programs that provide groceries to be prepared and eaten at home.

food poverty: hunger resulting from inadequate access to available food for various reasons, including inadequate resources, political obstacles, social disruptions, poor weather conditions, and lack of transportation.

food recovery: collecting wholesome food for distribution to low-income people who are hungry. Four common methods of food recovery are:

- *field gleaning:* collecting crops from fields that either have already been harvested or are not profitable to harvest.
- *nonperishable food collection:* collecting processed foods from wholesalers and markets.
- *perishable food rescue or salvage:* collecting perishable produce from wholesalers and markets.
- *prepared food rescue:* collecting prepared foods from commercial kitchens.

food security: certain access to enough food for all people at all times to sustain a healthy and active life.

soup kitchens: programs that provide prepared meals to be eaten on site.

HOW TO Identify Food Insecurity in a U.S. Household

To determine the extent of food insecurity in a household, surveys ask questions about behaviors and conditions known to characterize households having difficulty meeting basic food needs during the past 12 months. Most often, adults tend to protect their children from hunger. In the most severe cases, children also suffer from hunger and eat less.

1. Did you worry whether food would run out before you got money to buy more?
2. Did you find that the food you bought just didn't last and you didn't have money to buy more?
3. Were you unable to afford to eat balanced meals?
4. Did you or other adults in your household ever cut the size of your meals or skip meals because there wasn't enough food?
5. Did this happen in 3 or more months during the previous year?
6. Did you ever eat less than you felt you should because there wasn't enough money for food?
7. Were you ever hungry but didn't eat because you couldn't afford enough food?
8. Did you ever lose weight because you didn't have enough money to buy food?
9. Did you or other adults in your household ever not eat for a whole day because you were running out of money to buy food?
10. Did this happen in 3 or more months during the previous year?
11. Did you rely on only a few kinds of low-cost food to feed your children because you were running out of money to buy food?
12. Were you unable to feed your children a balanced meal because you couldn't afford it?
13. Were your children not eating enough because you just couldn't afford enough food?
14. Did you ever cut the size of your children's meals because there wasn't enough money for food?
15. Were your children ever hungry but you just couldn't afford enough food?
16. Did your children ever skip a meal because there wasn't enough money for food?
17. Did this happen in 3 or more months during the previous year?
18. Did your children ever not eat for a whole day because there wasn't enough money for food?

The more positive responses, the greater the food insecurity. Households with children answer all of the questions and are categorized as follows:

- ≤2 positive responses = food secure
- 3–7 positive responses = low food security
- ≥8 positive responses = very low food security

Households without children answer the first 10 questions and are categorized as follows:

- ≤2 positive responses = food secure
- 3–5 positive responses = low food security
- ≥6 positive responses = very low food security

Figure H16-1 (below) shows the results of the 2005 surveys.

money. In the United States, an estimated one out of eight people (including one out of six children) lives in poverty. Even those above the poverty line may not have food security. Physical and mental illnesses and disabilities, unemployment, low-paying jobs, unexpected or ongoing medical expenses, and high living expenses threaten their financial stability. When money is tight, people are forced to choose between food and life's other necessities—utilities, housing, and medical care. Food costs are more variable and flexible; people can choose to purchase fewer groceries to lower the monthly food bill, but they usually can't decide to pay only a portion of the bills for electricity, rent, or medication. Further contributing to food poverty are other problems such as abuse of alcohol and other drugs; lack of awareness of available food assistance programs; and the reluctance of people, particularly the elderly, to accept what they perceive as "welfare" or "charity." Lack of resources remains the major cause of food poverty, and solving this problem would do a lot to relieve hunger.

In the United States, poverty and hunger reach across various segments of society, most often touching single parents living in households with their children, Hispanics and African Americans, and individuals living in the inner cities. People living in poverty are simply unable to buy sufficient amounts of nourishing foods, even if they are wise shoppers. For many of the children in these families, school lunch (and breakfast, where available) may be the only nourishment for the day. Otherwise they go hungry, waiting for an adult to find money for food. Not surprisingly, these children are more likely to have health problems than those who eat regularly.[5] They also tend to perform poorly in school and in social situations.[6]

Ironically, hunger and obesity exist side by side in the United States—sometimes within the same person. It may seem paradoxical that in the same individual hunger reflects an inadequate food intake while obesity implies an excessive intake, but research studies have confirmed the relationship.[7] The highest rates of

obesity occur among those living in the greatest poverty—the same people who live with food insecurity.[8] Unfortunately, many healthful food choices cost more than energy-dense foods that foster weight gain but offer few, if any, nutrients.[9] Foods such as doughnuts, pizzas, and hamburgers provide the most energy and satiety for the least cost. Furthermore, people who are unsure about their next meal are likely to overeat when food or money is available. Interestingly, food-insecure people who do not participate in food assistance programs have a greater risk of obesity than those who do participate—illustrating that providing food actually helps to prevent obesity.[10] The accompanying "How to" offers shopping tips for those on a limited budget.

Relieving Hunger in the United States

The American Dietetic Association (ADA) calls for aggressive action to bring an end to domestic food insecurity and hunger and to achieve food and nutrition security for everybody living in the United States.[11] Many federal and local programs aim to prevent or relieve malnutrition and hunger in the United States.

Adequate nutrition and food security are essential in supporting good health and achieving the public health goals of the United States. To that end, an extensive network of federal assistance programs provides life-giving food to millions of U.S. citizens daily. One out of every six Americans receives food assistance of some kind, at a total cost of over $40 billion per year. Even so, the programs are not fully successful in preventing hunger, but they do seem to improve the nutrient intakes of those who participate. Programs described in earlier chapters include the WIC program for low-income pregnant women, breastfeeding mothers, and their young children (Chapter 14); the school lunch, breakfast, and child-care food programs for children (Chapter 15); and the food assistance programs for older adults such as congregate meals and Meals on Wheels (Chapter 16).

AP/Wide World Photos

The fight against hunger depends on the helping hands of caring volunteers.

The Food Stamp Program, administered by the U.S. Department of Agriculture (USDA), is the largest of the federal food assistance programs, both in amount of money spent and in number of people served. It provides assistance to almost 26 million people at a cost of over $25 billion per year; more than half of the recipients are children.[12] The USDA issues debit cards through state agencies to households—people who buy and prepare food together. The amount a household receives depends on its size, resources, and income. The average monthly benefit is about $86 per person.[13] Recipients may use the cards to purchase food and food-bearing plants and seeds,

HOW TO Plan Healthy, Thrifty Meals

Chapter 2 introduced the USDA MyPyramid Food Guide and principles for planning a healthy diet. Meeting that goal on a limited budget adds to the challenge. To save money and spend wisely, plan and shop for healthy meals with the following tips in mind:

Planning

- Make a grocery list before going to the store to avoid expensive "impulse" items.
- Do not shop when hungry.
- Use leftovers.
- Center meals on rice, noodles, and other grains.
- Use small quantities of meat, poultry, fish, or eggs.
- Use legumes instead of meat, poultry, fish, or eggs several times a week.
- Use cooked cereals such as oatmeal instead of ready-to-eat breakfast cereals.
- Cook large quantities when time and money allow.
- Check for sales and clip coupons for products you need; plan meals to take advantage of sale items.

Shopping

- Buy day-old bread and other products from the bakery outlet.
- Select whole foods instead of convenience foods (potatoes instead of instant mashed potatoes, for example).
- Try store brands.
- Buy fresh produce that is in season; buy canned or frozen items at other times.
- Buy only the amount of fresh foods that you will eat before it spoils. Buy large bags of frozen items or dry goods; when cooking, take out the amount needed and store the remainder.
- Buy fat-free dry milk; mix and refrigerate quantities needed for a day or two. Buy fresh milk by the gallon or half-gallon.
- Buy less expensive cuts of meat. Chuck and bottom round roast are usually inexpensive; cover during cooking and cook long enough to make meat tender. Buy whole chickens instead of pieces.
- Compare the unit price (cost per ounce, for example) of similar foods so that you can select the least expensive brand or size.
- Buy nonfood items such as toilet paper and laundry detergent at discount stores instead of grocery stores.

For daily menus and recipes for healthy, thrifty meals, visit the USDA Center for Nutrition Policy and Promotion: www.usda.gov/cnpp.

but not to buy tobacco, cleaning items, alcohol, or other nonfood items.

The Food Stamp Program improves nutrient intakes significantly, but hunger continues to plague the United States. Of the estimated 2 million homeless people in the United States who are eligible for food assistance, only 15 percent of single adults and 50 percent of families receive food stamps.

Efforts to resolve the problem of hunger in the United States do not depend solely on federal assistance programs. National **food recovery** programs have made a dramatic difference. The largest program, Second Harvest, coordinates the efforts of more than 40,000 **food pantries, emergency shelters,** and **soup kitchens** that feed over 25 million people a year.

Each year, an estimated one-fifth of our food supply is wasted in fields, commercial kitchens, grocery stores, and restaurants—that's enough food to feed 49 million people. Food recovery programs collect and distribute good food that would otherwise go to waste. Volunteers might pick corn left in an already harvested field, a grocer might deliver ripe bananas to a local **food bank,** and a caterer might take leftover chicken salad to a community shelter, for example. All of these efforts help to feed the hungry in the United States.

Food recovery programs depend on volunteers. Concerned citizens work through local agencies and churches to feed the hungry. Community-based food pantries provide groceries, and soup kitchens serve prepared meals. These meals often deliver adequate nourishment, but most homeless people receive fewer than one and a half meals a day, so many are still inadequately nourished. Combinations of various strategies help to build food security in a community.[14]

Each person's choice to get involved and be heard can help lead to needed change.

Solutions

Every segment of our society can join in the fight against hunger and poverty and help improve the political and environmental policies that surround them. The federal government, the states, local communities, big business and small companies, educators, and all individuals, including dietitians and foodservice managers, have many opportunities to resolve these problems.

Government policies that encourage sustainable food production protect the environment while using less energy and fewer resources. A healthy environment enhances our ability to produce enough food to meet the needs of all hungry people.

Businesses can take the initiative to help; some already have. Several large corporations are major supporters of antihunger programs. Many grocery stores and restaurants participate in food recovery programs by giving their leftover foods to community distribution centers.

Educators, including nutrition educators, can teach others about the underlying social and political causes of poverty, the root cause of hunger. At the college level, they can teach the relationships between hunger and population, hunger and environmental degradation, hunger and the status of women, and hunger and global economics. They can advocate legislation to address these problems. They can teach the poor to develop and run nutrition programs in their own communities and to fight on their own behalf for antipoverty, antihunger legislation.

Dietitians and foodservice managers have a special role to play, and their efforts can make an impressive difference. Their professional organization, the ADA, urges members to conserve resources and minimize waste in both their professional and their personal lives.[15] In addition, the ADA urges its members to educate themselves and others on hunger, its consequences, and programs to fight it; to conduct research on the effectiveness and benefits of programs; and to serve as advocates on the local, state, and national levels to help end hunger in the United States.[16] Globally, the ADA supports programs that combat malnutrition, provide food security, promote self-sufficiency, respect local cultures, protect the environment, and sustain the economy.[17]

Individuals can assist the global community in solving its poverty and hunger problems by joining and working for hunger-relief organizations (see Table H16-1). They can also support organizations that lobby for the needed changes in U.S. economic policies toward developing countries.

"Be part of the solution, not part of the problem," an adage says. In other words, don't waste time or energy moaning and groaning about how bad things are: do something to improve them. This adage is as applicable to today's global environmental problems as it is to an unwashed dish in the kitchen sink. They are our problems: human beings created them, and human beings must solve them.

Nutrition in the Clinical Setting

For a busy health practitioner, it can be easy to put a patient's nutritional needs on the back burner. After all, the benefits of diet therapy are not always as obvious or immediate as those of other medical treatments. Health practitioners who want to provide the best care for their patients, however, soon learn that an appropriate diet can improve both short-term and long-term outcomes of many disease treatments. Moreover, patients are often concerned about the impact their diet has on their disease condition. The remaining chapters of this book will show how dietary treatments can contribute to medical care and improve the quality of life for people who have become ill.

CHAPTER 17

Nutrition Care and Assessment

CHAPTER OUTLINE

Nutrition in Health Care • Effects of Illness on Nutrition Status • Responsibility for Nutrition Care • Nutrition Screening • The Nutrition Care Process

Nutrition Assessment • Historical Information • Food Intake Data • Anthropometric Data • Biochemical Data • Medical Tests and Procedures • Physical Examinations

HIGHLIGHT 17 Nutrition and Immunity

Previous chapters of this book introduced the nutrients and described how the appropriate dietary choices can support good health. Turning now to clinical nutrition, the remaining chapters describe how various medical disorders can affect nutrition status and nutrient needs. This chapter introduces the process that is used for providing nutrition care and the strategies used for assessing nutrition status.

Nutrition in Health Care

Malnutrition is frequently reported in patients hospitalized with acute illness, and acutely ill individuals without nutrition problems on admission often exhibit a subsequent decline in nutrition status. In the past few decades, estimates of malnutrition in hospital patients have ranged from 38 to 62 percent.[1] Poor nutrition status weakens immune function and compromises a person's healing ability, influencing both the course of disease and the body's response to treatment. Thus, preventing and correcting nutrition problems can improve the outcome of disease treatments and can also help to prevent complications.

Effects of Illness on Nutrition Status

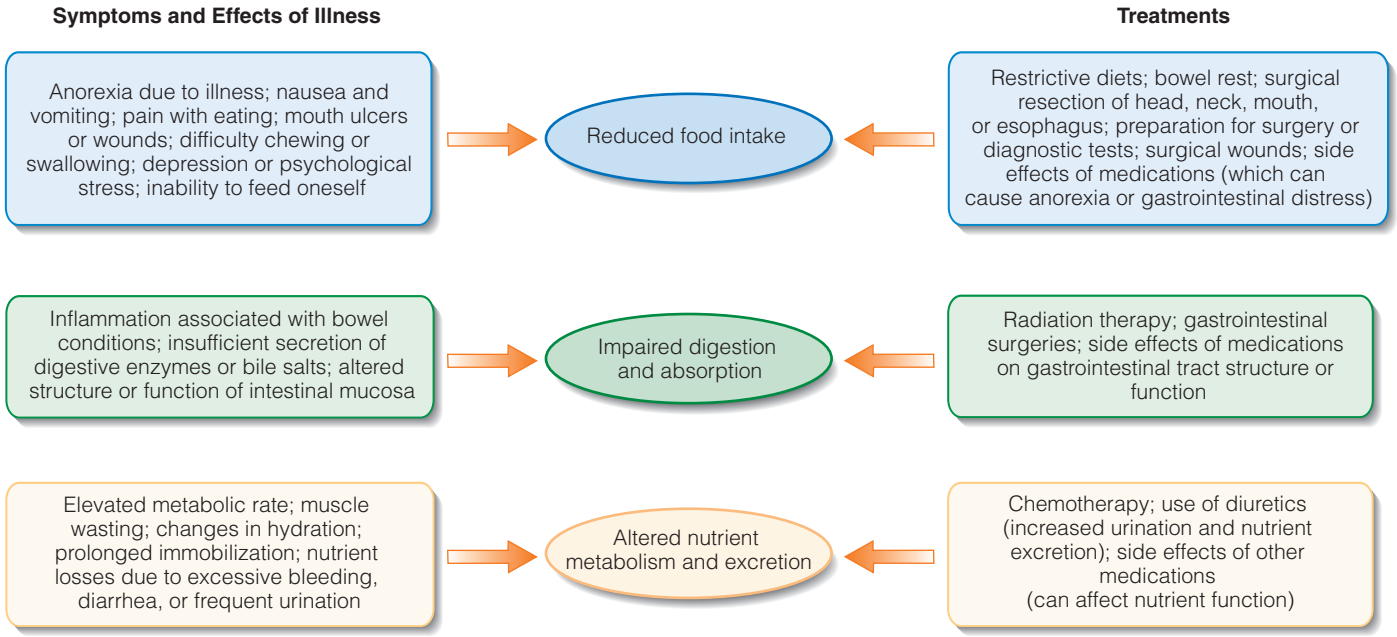
An illness, its symptoms, and its treatments can lead to malnutrition by reducing food intake, interfering with digestion and absorption, or altering nutrient metabolism and excretion (see Figure 17-1 on p. 590). For example, the nausea associated with some illnesses and disease treatments can diminish appetite and reduce food intake; similarly, an inflamed mouth or esophagus can make the physical act of eating uncomfortable. Certain medications can cause anorexia or gastrointestinal discomfort or can interfere with nutrient function and metabolism. Prolonged bed rest often results in **pressure sores,** which increase metabolic stress and raise protein and energy needs. ◆

The dietary changes required during an acute illness are usually temporary and can be tailored to accommodate an individual's preferences and lifestyle.

◆ Chapter 22 discusses the nutrition needs of patients undergoing acute metabolic stress.

pressure sores: regions of damaged skin and tissue due to prolonged pressure on the affected area by an external object, such as a bed, wheelchair, or cast; vulnerable areas of the body include buttocks, hips, and heels. Also called *decubitus* (deh-KYU-bih-tus) *ulcers.*

FIGURE 17-1 Ways in Which Illness Can Affect Nutrition Status



Conversely, chronic illnesses may necessitate long-term dietary modifications. For example, diabetes treatment requires lifelong changes in diet and lifestyle that some people may find difficult to maintain. The challenge for health professionals is to help their patients appreciate the potential benefits of treatment and accept dietary changes that can improve their health.

Responsibility for Nutrition Care

The members of a health care team work together to ensure that the nutritional needs of patients are met during illness. The roles of these team members in nutrition care may overlap, and job descriptions in different institutions may vary somewhat. In some cases, nutrition care is incorporated into the medical care plan developed by the entire health care team. Such plans, called **critical pathways,** outline coordinated plans of care for specific medical diagnoses, treatments, or procedures.

Physicians Physicians are responsible for meeting all of a patient's medical needs, including nutrition. They prescribe **diet orders** and other orders related to nutrition care, including referrals for medical nutrition therapy and dietary counseling. Physicians rely on nurses, registered dietitians, and other health professionals to alert them to nutrition problems, suggest strategies for handling these problems, and provide nutrition services.

Registered Dietitians Registered dietitians ◆ are food and nutrition experts who are uniquely qualified to provide **medical nutrition therapy.** They conduct nutrition and dietary assessments; diagnose nutrition problems; develop, implement, and evaluate **nutrition care plans** (described in a later section); plan and approve menus; and provide nutrition education. Registered dietitians may also work as managers of food and cafeteria services in health care institutions.

Registered Dietetic Technicians Registered dietetic technicians often work in partnership with registered dietitians and assist in the implementation and monitoring of nutrition services. Depending on their background and experience, they may screen patients for nutrition problems, provide patient education and counseling, de-

◆ Reminder: A *registered dietitian (RD)* has successfully completed the education and training specified by the the American Dietetic Association (or Dietitians of Canada), including an undergraduate degree in nutrition or dietetics, a supervised internship, and a national examination.

critical pathways: coordinated programs of treatment that merge the care plans of different health practitioners; also called *clinical pathways.*

diet orders: specific instructions regarding dietary management; also called *diet prescriptions.*

medical nutrition therapy: nutrition care provided by a registered dietitian; includes assessing nutrition status, diagnosing nutrition problems, and providing nutrition care.

nutrition care plans: strategies for meeting an individual's nutritional needs.

velop menus and recipes, ensure appropriate meal delivery, and monitor patients' food choices and intakes. Dietetic technicians sometimes supervise foodservice operations and may have roles in purchasing, inventory, quality control, sanitation, or safety.

Nurses Nurses interact closely with patients and thus are in an ideal position to identify people who would benefit from nutrition services. They often screen patients for nutrition problems and may participate in nutrition assessments. Nurses also provide direct nutrition care, such as encouraging patients to eat, finding practical solutions to food-related problems, recording a patient's food intake, and answering questions about special diets. As members of **nutrition support teams,** nurses are responsible for administering tube and intravenous feedings. In facilities that do not employ registered dietitians, nurses often assume responsibility for much of the nutrition care. Table 17-1 provides examples of **nursing diagnoses** that are likely to be associated with nutrition problems.

Other Health Care Professionals Other health care professionals may assist with nutrition care. Pharmacists, physical therapists, occupational therapists, speech therapists, social workers, nursing assistants, and home health care aides can be instrumental in alerting dietitians or nurses to nutrition problems or may share relevant information about a patient's health status or personal needs.

Nutrition Screening

To identify patients who are malnourished or at risk for malnutrition, a **nutrition screening** is conducted within 24 hours of a patient's admission to a hospital or other extended-care facility. It may also be included in outpatient services and community health programs. ◆ A nutrition screening involves collecting a limited amount of health-related information that can identify malnutrition (most often, protein-energy malnutrition, or PEM ◆). Although the screening should be sensitive enough to identify the patients who require nutrition care, it must be simple enough to be completed within 10 to 15 minutes. Usually a nurse, nursing assistant, registered dietitian, or dietetic technician performs and documents the screening. In some instances, a screening may be repeated (or followed up with a more comprehensive screening) during a patient's stay.

The information gathered during a nutrition screening varies according to the patient population, the type of care offered by the health care facility, and the patient's medical problem. Usually included are the admitting diagnosis, physical measurements, laboratory test results, and information about diet and health provided by the patient or caregiver (see Table 17-2 for examples). A number of screening tools that use different combinations of these variables have become popular in recent years; these tools include the *Mini Nutritional Assessment* and the *Subjective Global Assessment*, outlined in Tables 17-3 (p. 592) and 17-4 (p. 593). The Mini

TABLE 17-1 Nursing Diagnoses with Nutritional Implications

- Chronic confusion
- Chronic pain
- Constipation
- Diarrhea
- Disturbed body image
- Feeding self-care deficit
- Imbalanced nutrition: less than body requirements
- Imbalanced nutrition: more than body requirements
- Impaired dentition
- Impaired oral mucous membrane
- Impaired physical mobility
- Impaired swallowing
- Ineffective infant feeding pattern
- Nausea
- Readiness for enhanced nutrition
- Risk for aspiration
- Risk for deficient fluid volume
- Risk for unstable blood glucose

SOURCE: NANDA International, *Nursing Diagnoses: Definitions and Classification 2007-2008* (Philadelphia: NANDA International, 2007).

◆ Reminder: The Nutrition Screening Initiative, which addresses malnutrition risk in older adults, is described in Chapter 16 (pp. 576–577).

◆ Reminder: *Protein-energy malnutrition (PEM)* is a deficiency of protein and food energy and is characterized by weight loss and loss of muscle tissue.

TABLE 17-2 Information Included in a Nutrition Screening

- Age, medical diagnosis, severity of illness
- Height and weight, BMI, unintentional weight changes
- Tissue wasting, loss of subcutaneous fat
- Changes in appetite or food intake
- Problems that interfere with food intake (such as chewing or swallowing difficulty, or nausea and vomiting)
- Food allergies or intolerances, extensive dietary restrictions
- Laboratory test results that indicate poor health status
- History of diabetes, renal disease, or other chronic illness
- Presence of anemia or pressure sores
- Use of medications that can impair nutrition status
- Depression, social isolation, dementia

nutrition support teams: health care professionals responsible for the provision of nutrients by tube feeding or intravenous infusion.

nursing diagnoses: clinical judgments about actual or potential health problems that provide the basis for selecting appropriate nursing interventions.

nutrition screening: a brief assessment of health-related variables to identify patients who are malnourished or at risk for malnutrition.

TABLE 17-3 Mini Nutritional Assessment[a]

The Mini Nutritional Assessment is a two-part screening tool consisting of a brief screening step and, if warranted, a more detailed assessment. A referral for nutrition care is warranted if the combined scores from Step 1 and Step 2 indicate that the patient is malnourished or at risk for malnutrition.

Step 1: Screening

The patient or caregiver provides answers to questions A through D, and the screener determines answers to questions E and F. If the sum of points is 11 or less, the patient is at risk for malnutrition and Step 2 is conducted. A sum of 12 or more suggests that the patient is not at risk. Point values are shown below each question.

A. Has food intake declined in the past 3 months due to loss of appetite, digestive problems, or chewing or swallowing difficulties?

0 = severe loss of appetite; 1 = moderate loss of appetite; 2 = no loss of appetite

B. Any weight loss during the past 3 months?

0 = weight loss >3 kg; 1 = does not know; 2 = weight loss of 1 to 3 kg; 3 = no weight loss

C. Any mobility problems?

0 = cannot leave bed or chair; 1 = cannot leave house; 2 = able to leave house

D. Any psychological stress or acute disease in the past 3 months?

0 = yes; 2 = no

E. Any neuropsychological problems?

0 = severe dementia or depression; 1 = mild dementia; 2 = no psychological problems

F. Healthy BMI?

0 = BMI is <19; 1 = BMI is 19 to <21; 2 = BMI is 21 to <23; 3 = BMI is ≥23

Step 2: Assessment

The patient or caregiver provides answers to questions G through P, and the screener determines answers to questions Q and R. The total score includes the sum of points from both Step 1 and Step 2. A total score of less than 17 points suggests that the patient is malnourished; a score of 17 to 23.5 points indicates risk of malnutrition.

G. Lives independently? 0 = no; 1 = yes

H. Takes more than 3 prescription drugs per day? 0 = yes; 1 = no

I. Presence of pressure sores or skin ulcers? 0 = yes; 1 = no

J. Number of full meals consumed daily? 0 = 1 meal; 1 = 2 meals; 2 = 3 meals

K. Intake of protein-containing foods?

- At least 1 serving of milk products per day? (yes/no)
- 2 or more servings of legumes or eggs per week? (yes/no)
- Meat, fish, or poultry every day? (yes/no)

0 = 0 or 1 "yes" response; 0.5 = 2 "yes" responses; 1 = 3 "yes" responses

L. At least 2 servings of fruits and vegetables per day? 0 = no; 1 = yes

M. Amount of fluid consumed daily?

0 = <3 cups; 0.5 = 3 to 5 cups; 1 = >5 cups

N. Needs assistance with feeding?

0 = needs assistance; 1 = self-fed with some difficulty; 2 = no assistance needed

O. Patient's view of own nutritional status?

0 = feels malnourished; 1 = uncertain; 2 = feels adequately nourished

P. Patient's view of own health status in comparison with others?

0 = not as good; 0.5 doesn't know; 1 = as good as others; 2 = better than others

Q. Midarm circumference in centimeters? 0 = <21; 0.5 = 21 to <22; 1 = ≤22

R. Calf circumference in centimeters? 0 = <31; 1 = ≥31

Nutritional Assessment was developed to detect malnutrition in adults over 65 years of age, whereas the Subjective Global Assessment has been found to be applicable to a variety of patient populations. Briefer screening methods may use just two or three variables; for example, a tool called the *Nutrition Risk Index* determines

TABLE 17-4 Subjective Global Assessment

The Subjective Global Assessment rates features of the medical history and physical examination. Each variable is given an A, B, or C rating: A for well nourished, B for potential or mild malnutrition, and C for severe malnutrition. Patients are classified according to the final numbers of A, B, and C rankings.

Medical History

- Body weight changes: percentage change in past 6 months; weight change in past 2 weeks
- Dietary changes: suboptimal, low-kcalorie, liquid diet, or starvation
- GI symptoms: nausea, diarrhea, vomiting, or anorexia for more than 2 weeks
- Functional ability: full capacity versus suboptimal, walking versus bedridden
- Degree of disease-related metabolic stress: low, medium, or high

Physical Examination

- Subcutaneous fat loss (triceps or chest)
- Muscle loss (quadriceps or deltoids)
- Ankle edema
- Sacral (lower spine) edema
- Ascites (abdominal edema)

Classification:

A: Well nourished: if no significant loss of weight, fat, or muscle tissue and no dietary difficulties, functional impairments, or GI symptoms; also applies to patients with recent weight gain and improved appetite, functioning, or medical prognosis

B: Moderate malnutrition: if 5 to 10 percent weight loss, mild loss of muscle or fat tissue, decreased food intake, and digestive or functional difficulties that impair food intake; the B classification usually applies to patients with an even mix of A, B, and C ratings

C: Severe malnutrition: if more than 10 percent weight loss, severe loss of muscle or fat tissue, edema, multiple GI symptoms, and functional impairments

SOURCES: R. S. Gibson, *Principles of Nutritional Assessment* (New York: Oxford University Press, 2005), pp. 809–826; A. S. Detsky and coauthors, What is subjective global assessment of nutritional status? *Journal of Parenteral and Enteral Nutrition* 11 (1987): 8–13.

malnutrition risk by evaluating weight loss and serum albumin levels.[2] Note that there is no single screening method that is universally accepted, and health care institutions often develop specific techniques that meet their particular needs.

A nutrition or health screening may lead to a referral for nutrition care. The following section describes the next stage of the process: the method used by dietitians to address nutritional concerns.

The Nutrition Care Process

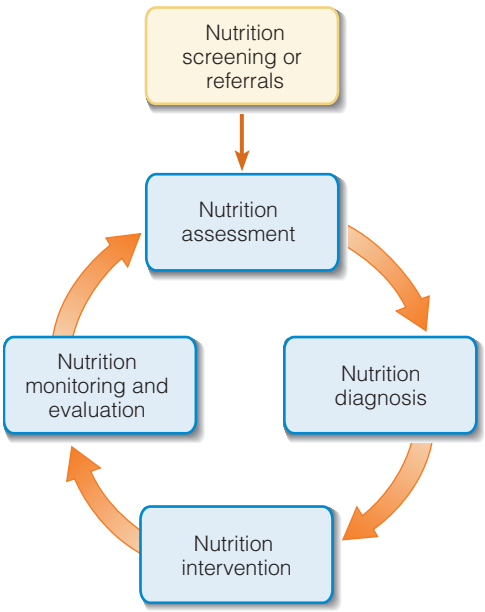
Registered dietitians use a systematic approach to medical nutrition therapy called the **nutrition care process.** ◆ Figure 17-2 presents the four distinct, yet interrelated, steps of the nutrition care process:[3]

1. Nutrition assessment
2. Nutrition diagnosis
3. Nutrition intervention
4. Nutrition monitoring and evaluation

Although the nutrition care process is easiest to visualize as a series of steps, the steps are frequently revisited in order to reassess and revise diagnoses and intervention strategies. Note that each step of the nutrition care process must be documented in the medical record, providing a record for future reference and facilitating communication among members of the health care team. Chapter 18 provides additional information about documentation.

Nutrition Assessment A nutrition assessment involves the collection and analysis of health-related information for the purpose of identifying specific nutrition

FIGURE 17-2 The Nutrition Care Process



◆ As a comparison, the *nursing process* consists of five steps:
1. Assessment
2. Nursing diagnosis
3. Outcome identification and planning
4. Implementation
5. Evaluation

nutrition care process: a problem-solving method that dietetics professionals use to evaluate and treat nutrition-related problems.

TABLE 17-5 Examples of Nutrition Diagnoses

Intake Diagnoses

- Excessive alcohol intake
- Inadequate energy intake
- Inadequate fluid intake
- Inappropriate infusion of parenteral nutrition
- Increased calcium needs
- Inconsistent carbohydrate intake

Clinical Diagnoses

- Altered blood potassium levels
- Altered GI function (constipation)
- Breastfeeding difficulty
- Food-medication interaction
- Involuntary weight gain
- Swallowing difficulty

Behavioral-Environmental Diagnoses

- Disordered eating pattern
- Impaired ability to prepare meals
- Limited access to food
- Physical inactivity
- Self-feeding difficulty
- Undesirable food choices

SOURCE: American Dietetic Association, *Nutrition Diagnosis and Intervention: Standardized Language for the Nutrition Care Process* (Chicago: American Dietetic Association, 2007).

problems and their underlying causes. A well-conducted assessment allows the dietitian to devise a plan of action to prevent or correct nutrient imbalances or to evaluate whether a particular care plan is working. An assessment typically includes information from medical, personal, social, and food/nutrition histories; anthropometric and biochemical analyses; medical tests; and a physical examination. When appropriate, assessment data are compared with reliable standards to help with their interpretation. The second half of this chapter describes the components of nutrition assessment in detail.

Nutrition Diagnosis After completing a nutrition assessment, the dietitian identifies existing and potential nutrition problems, a step that requires a careful and objective analysis of the patterns and relationships among the assessment data. Each nutrition problem receives a separate diagnosis, which includes the specific problem, etiology or cause, and signs and symptoms that provide evidence of the problem.[4] ◆ For example, a potential nutrition diagnosis might be "Involuntary weight gain *(the problem)* related to chronic use of a medication (corticosteroids) that causes weight gain *(the etiology or cause)* as evidenced by an unintentional weight gain of 10 percent of body weight over the past six months *(the sign or symptom)*." Note that a nutrition diagnosis is likely to change over the course of illness, due to either a successful nutrition intervention or resolution of the medical problem.

Nutrition diagnoses fall into three main categories: *intake, clinical,* and *behavioral-environmental.* Intake-related diagnoses involve either the inadequate or excessive ingestion of nutrients, energy, fluid, alcohol, dietary supplements, and food ingredients. Clinical diagnoses involve medical or physical conditions that disrupt nutrition status, such as disruptions in physiological or mechanical functioning, altered nutrient metabolism, and body weight problems. Behavioral-environmental diagnoses include problems related to the patient's knowledge, attitudes, or beliefs; the physical environment; access to food; and food safety. Table 17-5 lists examples of nutrition diagnoses in each of these categories.

◆ This format is called a *PES statement* because it includes the *P*roblem, the *E*tiology, and the *S*igns and symptoms.

Nutrition Intervention After nutrition problems are identified, the appropriate nutrition care is planned and implemented. Nutrition interventions attempt to modify dietary and lifestyle practices or environmental conditions that interfere with nutrition status or health. When possible, the intervention targets the etiology or cause of the problem as identified in the nutrition diagnosis. Nutrition interventions often include both counseling and education components, which require close interaction with the patient. To be successful, the intervention must carefully consider the patient's dietary and lifestyle preferences. Note that nutrition interventions used by dietitians are *evidence based;* that is, they are based on scientific rationale and supported by the results of high-quality research.[5] ◆

◆ The American Dietetic Association maintains an Evidence Analysis Library to keep members updated about recent developments in nutrition and dietetics research.

The goals of nutrition interventions are stated in terms of measurable outcomes, such as the results of laboratory or anthropometric tests. For example, goals for an overweight person with diabetes might include target ranges for blood glucose levels and body weight. Other desirable outcomes include positive changes in dietary behaviors and lifestyle; for example, the diabetes patient may need to learn how to control carbohydrate intake or portion sizes and may benefit from regular exercise. These outcomes can be assessed during an interview with the patient.

Although many aspects of nutrition care fall within the scope of dietetics practice, others require the assistance of other health professionals. For example, a physician's help would be required if a medication interfered with food intake; the nursing or foodservice staff might be involved if the feeding environment or meal delivery required adjustment. Chapter 18 provides additional information about nutrition intervention.

Nutrition Monitoring and Evaluation The effectiveness of the nutrition care plan must be evaluated periodically: the original goals and outcome measures should be reviewed and compared with updated assessment data, and the patient's progress should be monitored carefully. Sometimes a change in a person's situation alters nutritional needs; for example, a change in the medical treatment or a new medication

may alter a person's tolerance to certain foods. A nutrition care plan must be flexible enough to adapt to the new situation.

If progress is slow or a patient is unable or unwilling to make the suggested changes, the care plan should be redesigned and take into account the reasons why the earlier plan was not successful. The new plan may need to include motivational techniques or additional patient education. If the patient remains unwilling to modify behaviors despite the expected benefits, the health care provider can try again at a later time when the patient may be more receptive.

IN SUMMARY

Illnesses and their treatments can affect food intake and nutrient needs, leading to malnutrition. In turn, poor nutrition can reduce the effectiveness of medical treatments. The combined efforts of each member of the health care team ensure that patients receive optimal nutrition care. Nutrition screening identifies individuals who can benefit from nutrition assessment and follow-up nutrition care. The nutrition care process includes four interrelated steps: nutrition assessment, nutrition diagnosis, nutrition intervention, and nutrition monitoring and evaluation.

Nutrition Assessment

As described earlier in this chapter, a nutrition assessment provides the information needed for diagnosing nutrition problems and designing a nutrition care plan, and follow-up assessments help to determine whether the care plan has been effective. Ideally, the assessment should be sensitive enough to detect subtle nutrition problems and specific enough to identify problem nutrients. For most nutrient imbalances, a variety of tests are necessary to identify nutrition problems. The remainder of this chapter describes the types of information and measures that are most commonly obtained in a nutrition assessment.

Historical Information

Historical information provides clues about the patient's nutrition status and nutrient needs and uncovers personal preferences that need to be considered when developing a nutrition care plan. Table 17-6 summarizes the various types of historical information that contribute to a nutrition assessment.[6] This information can be obtained from the medical record or by interviewing the patient or caregiver. ◆

◆ The terms used in this section are based on the standardized language developed by the American Dietetic Association; other resources may use different terminology.

TABLE 17-6 Historical Information Used in Nutrition Assessment[a]

Medical/Health History	Medication/Supplement History	Personal/Social History	Food/Nutrition History
Current complaint(s)	Prescription drugs	Age	Food intake
Past medical conditions	Over-the-counter drugs	Occupation	Food allergies and intolerances
Surgical history	Dietary/herbal supplements	Educational level	Nutrition/health knowledge
Family medical history	Alcohol intake	Socioeconomic status	Food availability
Chronic disease risk	Cigarettes/tobacco use	Cultural/ethnic identity	Physical activity and exercise patterns
Mental/emotional health status	Illegal drug use	Religious beliefs	
		Home/family situation	
		Cognitive abilities	

[a]Historical information can be categorized in different ways; the categories shown here conform to the standardized language used in nutrition diagnoses.

TABLE 17-7 Medical Problems Often Associated with Malnutrition

- Acquired immune deficiency syndrome (AIDS)
- Alcoholism
- Anorexia nervosa
- Bulimia nervosa
- Burns (extensive or severe)
- Cancer and cancer treatments
- Cardiovascular diseases
- Celiac disease
- Chewing/swallowing difficulties
- Chronic kidney disease
- Dementia
- Diabetes mellitus
- Feeding disabilities
- Infections
- Inflammatory bowel diseases
- Liver disease
- Malabsorption
- Mental illness
- Pressure sores
- Surgery (major)
- Vomiting (prolonged or severe)

Medical/Health History A substantial number of medical problems and their treatments may either interfere with food intake or require dietary changes; Table 17-7 lists examples. The medical history generally includes the family medical history as well; this information reveals a person's genetic susceptibilities for diseases that can potentially be prevented with dietary and lifestyle changes. (Note that the family medical history refers to blood relatives only.)

Medication/Supplement History A number of medications have detrimental effects on nutrition status, and various dietary components can alter drug absorption or metabolism. Chapter 19 provides examples of notable diet-drug interactions that may need consideration when planning nutrition care. Use of alcohol, tobacco, or illegal drugs may alter food intake and ultimately have disruptive effects on health and nutrition status.

Personal/Social History Personal and social factors influence food choices, as well as a person's ability to manage health and nutrition problems. For example, financial concerns may restrict access to health care and nutritious foods. Cultural background or religious beliefs can affect food preferences. Certain family members may be responsible for preparing or procuring food. An individual with cognitive disabilities may eat poorly or be unable to follow complex dietary instructions.

Food/Nutrition History A food/nutrition history (often called a *diet history*) is a detailed account of a person's dietary practices. It includes food intake data, lifestyle habits, and information about the various factors that may influence dietary choices, such as the person's knowledge or beliefs about nutrition and health. Although different methods are used for collecting food intake data, the procedure often includes an interview about recent food intake (for example, a *24-hour recall*) and a survey of usual food choices (such as a *food frequency questionnaire*). A good food/nutrition history can uncover current or potential nutrition problems, as well as patterns of behavior that contribute to health problems. The following section describes the most common methods of gathering food intake information.

Food Intake Data

Obtaining accurate food intake data is challenging, and results may vary depending on the individual's memory and honesty and the assessor's skill and training. In addition, each method has its own strengths and weaknesses, so best results are obtained by using a combination of methods. Table 17-8 summarizes the methods commonly used and each method's advantages and disadvantages.

Once food intake data are collected, the nutrient intake can be estimated using dietary analysis software or a table of food composition (such as that in Appendix H) and nutrient intake levels can be compared with RDA and AI values. Another option is to compare the food list with a diet-planning guide such as the USDA Food Guide (see Chapter 2). The food list also reveals a person's food preferences, which are helpful for developing an appropriate nutrition care plan, planning menus, or providing dietary counseling.

The 24-Hour Recall The **24-hour recall** is a guided interview in which an individual recounts all of the foods and beverages consumed in the past 24 hours or during the previous day. The interviewer includes questions about the times when meals or snacks were eaten, amounts consumed, and ways in which foods were prepared. Accuracy can be improved by prompting the respondent to recall food items that are often forgotten, such as snack foods, beverages, and condiments.

In a typical interview, the assessor may begin by asking: "What is the first thing you ate or drank yesterday morning?" After the first food items are described, the follow-up questions might be: "What time was that?" and "How much did you eat?" Questioning continues until the intake record for the day is complete. Food models or measuring cups and spoons can be used to help the individual visualize and describe the amounts consumed. After the day's intake is recounted, the interviewer asks whether the intake that day is fairly typical and, if not, how it varies

24-hour recall: a record of foods consumed in the previous 24 hours; sometimes modified to include foods consumed in a typical day.

TABLE 17-8 Methods for Obtaining Food Intake Data

Method	Description	Advantages	Disadvantages
24-hour recall	Guided interview in which the foods and beverages consumed in a 24-hour period are described in detail.	• Results are not dependent on literacy or educational level of respondent. • Interview occurs after food is consumed, so it does not interfere with food choices. • It is a relatively easy and quick assessment method.	• Process is reliant on memory. • Food items that cause embarrassment (alcohol, desserts) may be omitted. • Underestimation and overestimation of food intakes are common. • Skill of interviewer affects outcome. • Data from a single day cannot represent the respondent's usual intake accurately. • Seasonal variations may not be addressed.
Food frequency questionnaire	Written survey of food consumption during a specific period of time, often a one-year period.	• Process examines long-term food intake, so day-to-day and seasonal variability should not affect results. • It is completed after food is consumed, so it does not interfere with food choices. • It is a low-cost method.	• Process is reliant on memory. • It is not good for monitoring short-term changes in food intake. • Serving sizes are often difficult for respondents to evaluate without assistance. • Calculated nutrient intakes may not be accurate. • Food lists include common foods only. • Food lists for the general population are of limited value in special populations.
Food record	Written account of food consumed during a specified period, usually several consecutive days. Accuracy is improved by including weights or measures of foods.	• Process does not rely on memory. • Recording foods as they are consumed improves likelihood of obtaining accurate food intake data. • It is useful for controlling intake because keeping records can increase awareness of food choices.	• Recording process itself influences food intake. • Process is time-consuming and burdensome for respondent; requires high degree of motivation. • Underreporting is common. • It requires literacy and the physical ability to write. • Seasonal changes in diet are not taken into account.
Direct observation	Observation of meal trays or shelf inventories before and after eating; possible only in residential facilities.	• Process does not rely on memory. • It does not interfere with person's food intake. • It can be used to evaluate acceptability of prescribed diet.	• Process is possible only in residential situations. • It is labor intensive.

from the person's usual intake. A recall interview may be conducted on several nonconsecutive days to obtain a better representation of a person's usual diet.

A recall interview often yields useful data for developing an acceptable nutrition care plan and identifying food items that may need to be restricted due to illness. It is a poor technique, however, for determining the adequacy of a diet, because it does not take into account fluctuations in food intake or seasonal variations. Moreover, food intakes are often underestimated because the process relies on an individual's memory and reporting accuracy. People often forget to mention alcohol, soft drinks, snack foods, and desserts unless specifically prompted to do so, and some individuals find it embarrassing to report consumption of foods such as chocolate, butter, and red meat.[7]

Food Frequency Questionnaire A **food frequency questionnaire** surveys the foods and beverages regularly consumed during a specific time period. Some questionnaires are qualitative only: food lists contain common foods, organized by food group, with check boxes to indicate frequency of consumption. Other types of questionnaires provide semiquantitative information by including portion sizes as well. Figure 17-3 shows a sample section of a semiquantitative questionnaire that surveys fruit intake over the previous year. Because the respondent is often asked to estimate food intakes over a one-year period, the results should not be affected by seasonal changes in diet. Conversely, a disadvantage of this method is its inability to determine recent changes in food intake. In addition, food frequency questionnaires typically list only common foods, so food intake data are not as accurate as those obtained by dietary recall methods.

Simple versions of food frequency questionnaires focus on food categories relevant to a person's medical condition. For example, a questionnaire designed to evaluate calcium intake may include only milk products, fortified foods, certain fruits and vegetables, and dietary supplements that contain calcium. A computer analysis can then quickly estimate the individual's calcium intake and compare it with recommendations.

food frequency questionnaire: a survey of foods routinely consumed. Some questionnaires ask about the types of food eaten and yield only qualitative information; others include questions about portions consumed and yield semiquantitative data as well.

food record: a detailed log of food eaten during a specified time period, usually several days; also called a *food diary*. A food record may also include information regarding disease symptoms, physical activity, and medication use.

Food Record A **food record** is a written account of foods and beverages consumed during a specified time period, usually several consecutive days. Foods are recorded as they are consumed in order to obtain the most complete and accurate record possible; thus the process does not rely on memory. A detailed food record includes the types and amounts of foods and beverages consumed, times of consumption, and methods of preparation. For weight-management purposes, it may also include information about a person's mood (happy, stressed), the occasion (party, family meal), activities engaged in while eating (watching TV, driving to work), and daily physical activity. For establishing blood glucose control, the record may include information about medications, physical activity, and the results of blood glucose monitoring.

The food record provides valuable information about food intake, as well as a person's response to and compliance with medical nutrition therapy. Unfortunately,

food records require a great deal of time to complete, and people need to be highly motivated to keep accurate records. Another drawback is that the recording process itself may influence food intake. Furthermore, a reliable estimate of a person's overall nutrient intake is difficult to obtain when data are collected for just a few days or even a week, because of day-to-day and seasonal variations in food intake.

Direct Observation In facilities that serve meals, food intakes can be directly observed and analyzed. This method can also reveal a person's food preferences, changes in appetite, and any problems with a prescribed diet. Health practitioners use direct observation to conduct patients' **kcalorie counts** to determine the food energy (and often, protein) consumed by patients during a single day or several consecutive days. To perform a kcalorie count, the clinician estimates food intake by recording the dietary items that a patient is given at meals and subtracting the amounts remaining after meals are completed; this procedure allows an estimate of the kcaloric content of foods and beverages actually consumed. Although a useful means of discerning patients' intakes, direct observation requires regular and careful documentation and can be labor intensive and costly.

Food models and measuring utensils can help an individual visualize portion sizes.

Anthropometric Data

Anthropometric data ◆ can reveal problems related to both overnutrition and protein-energy malnutrition. Height (or length) and weight are the most widely used anthropometric measurements and help to evaluate growth in children and nutrition status in adults. Other helpful data include body composition tests (described in Chapter 8 and Appendix E) and circumferences of the head, waist, and limbs.

◆ Reminder: *Anthropometric* refers to physical measurements of the body.

Height (or Length) Poor growth in children can signify malnutrition. In adults, height measurements alone do not reflect current nutrition status but can be used for estimating a person's energy needs or appropriate body weight. Length is measured in infants and children younger than 24 months of age, and height is usually measured in older children and adults. ◆ Length can also be measured in adults and children who are unable to stand unassisted due to physical or medical reasons. The "How to" on p. 600 describes some standard techniques for measuring length and height.

◆ *Length* is measured while a person is recumbent (lying down), whereas *height* is measured while a person is standing upright.

In adults who are unable to stand, height can be estimated from equations that include either the knee height or the full-arm span, both of which correlate well with height.[8] Knee height extends from the top of the knee to the heel and is measured with a knee-height caliper while the individual is in a sitting position or lying flat on the back with the knee bent at a 90-degree angle. The full-arm span is the distance from the tip of one middle finger to the other when the arms are extended horizontally; it is measured most accurately when the measuring device is affixed to the wall and the subject is standing with the back to the wall and arms fully extended. In children with disabilities that affect stature, alternative measures of linear growth include the full-arm span, lower-leg lengths (knee to heel, similar to the knee-height measure), and upper-arm lengths (shoulder to elbow), which are compared with reference percentiles.

Body Weight During clinical care, health care providers must monitor body weights carefully: weight changes may reflect changes in hydration status, and involuntary weight losses may signify PEM. Body weights are typically compared with healthy ranges on height-weight tables and growth charts or used to calculate the body mass index (BMI). ◆ The "How to" on p. 600 includes suggestions for improving the accuracy of weight measurements.

◆ Reminder: $\text{BMI} = \dfrac{\text{weight (kg)}}{\text{height (m)}^2}$

A healthy BMI typically falls between 18.5 and 25.

Head Circumference A head circumference measurement helps to assess brain growth and malnutrition in children up to three years of age, although this measure is not necessarily reduced in a malnourished child. Head circumference values can also track brain development in premature and small-for-gestational-age infants. To measure head circumference, the assessor encircles the largest circumference measure

kcalorie counts: the determination of food energy (and often, protein) consumed by patients for one or more days.

HOW TO Measure Length and Height

To improve the accuracy of length and height measurements, keep the following in mind:

- Always measure—never ask! Self-reported heights are less accurate than measured heights. If height is not measured, document that the height is self-reported.
- Measure the length of infants and young children by using a measuring board with a fixed headboard and a movable footboard. It generally takes two people to measure length. One person gently holds the infant's head against the headboard; the other straightens the infant's legs and moves the footboard to the bottom of the infant's feet.
- Measure height next to a wall on which a nonstretchable measuring tape or board has been fixed. Ask the person to stand erect without shoes and with heels together. The person's eyes and head should be facing forward, with heels, buttocks, and shoulder blades touching the wall. Place a ruler or other flat, stiff object on the top of the head at a right angle to the wall, and carefully note the height measurement.
- Immediately record length and height measurements to the nearest $^1/_8$ inch or 0.1 centimeter.
- For evaluating growth rate in young children, use the appropriate growth chart (Appendix E) when plotting results. If length is measured, use the growth chart for children between 0 and 36 months; if height is measured, use the chart for individuals between 2 and 20 years.
- Higher values are obtained from supine measurements than from vertical height measurements due to gravity.

Janine Wiedel Photolibrary/Alamy

It takes two people to measure the length of an infant.

Standing erect allows for an accurate height measurement.

HOW TO Measure Weight

Tips for measuring weight include:

- Always measure—never ask! Self-reported weights are often inaccurate. If weight is not measured, document that the weight is self-reported.
- Valid weight measurements require scales that have been carefully maintained, calibrated, and checked for accuracy at regular intervals. Beam balance and electronic scales are the most accurate. Bathroom scales are inaccurate and inappropriate in the clinical setting.
- Measure an infant's weight with a scale that allows the infant to sit or lie down. The tray should be large enough to support an infant or young child up to 40 pounds, and the scale should weigh in $^1/_2$-ounce or 10-gram increments. For accurate results, weigh infants without clothes or diapers. Excessive movement by the infant can reduce accuracy.
- Children who can stand are weighed in the same way as adults, using beam balance or electronic scales with platforms large enough for standing comfortably. If repeated weight measurements are needed, each weighing should take place at the same time of day (preferably before breakfast), in the same amount of clothing, after the person has voided, and on the same scale. Record weights to the nearest $^1/_4$ pound or 0.1 kilogram.
- Special scales and hospital beds with built-in scales are available for weighing people who are bedridden.

Beam balance scales allow accurate weight measurements for older children and adults.

of a child's head with a nonstretchable measuring tape: the tape is placed just above the eyebrows and ears and around the occipital prominence at the back of the head (see the photo). The measurement is read to the nearest 1/8 inch or 0.1 centimeter.

Circumferences of Waist and Limbs The waist circumference correlates with abdominal fat and can help in assessing overnutrition (see Chapter 8, p. 263). Circumferences of the mid-upper arm, mid-thigh, and mid-calf regions can help in evaluating the effects of illness, aging, and PEM on skeletal muscle tissue. For improved accuracy, circumference measurements are often used together with skinfold measurements to correct for the subcutaneous fat in limbs.

Anthropometric Assessment in Infants and Children To evaluate growth patterns, periodic measurements of height (or length), weight, and head circumference are plotted on growth charts, such as those provided in Appendix E. ◆ The most commonly used growth charts compare height (or length) to age, weight to age, head circumference to age, weight to length, and BMI to age. Although individual growth patterns vary, a child's growth will generally stay at about the same percentile throughout childhood; a sharp drop in a previously steady growth pattern suggests malnutrition. Growth patterns that fall below the 5th percentile may also be cause for concern, although genetic influences must be considered when interpreting low values. Growth charts with BMI-for-age percentiles can be used to assess risk of underweight and overweight in children over two years of age: the 10th and 85th percentiles are used as cutoffs to identify children who may be malnourished or overweight, respectively.[9] Chapter 15 provides additional information about growth during infancy and childhood.

Anthropometric Assessment in Adults Weight and height are the primary anthropometric values monitored in adults. As mentioned previously, weight changes must be evaluated carefully during illness: although unintentional weight *loss* can indicate malnutrition, weight *gain* may result from fluid retention rather than overnutrition. Fluid retention often accompanies worsening disease in patients with heart failure, liver cirrhosis, and kidney failure, and it can mask the weight loss associated with PEM. In assessing the significance of weight loss, the rate should be considered as well as the amount: an involuntary weight loss of more than 10 percent within a six-month period suggests risk of PEM.[10] Note that certain types of medications can also contribute to weight changes.

To assess the degree of nutritional risk associated with illness, weight data are often expressed as "percent of ideal body weight" (%IBW) or "percent of usual body weight" (%UBW). Because a healthy body weight usually falls within a BMI range of 18.5 and 24.9, an "ideal weight" can be found using a BMI table or graph (see Figure 8-6, p. 260 or the inside back cover of this book).[11] The %IBW is not as useful as the %UBW for interpreting weight changes that occur in underweight, overweight, or obese individuals. In underweight patients, the %IBW can overestimate the degree of weight loss due to illness. In overweight or obese patients, the weight loss resulting from illness may be overlooked. ◆ General guidelines for estimating and evaluating %IBW and %UBW are provided in Table 17-9 and in the "How to" on p. 602.

Many of the illnesses discussed in later chapters are associated with losses in muscle tissue that resist nutrition intervention. In addition, losses in both muscle tissue and height are common with aging even though body weights may remain stable. Thus, health practitioners may utilize skinfold and limb circumference measurements to evaluate body composition changes that need to be addressed in the treatment plan.

© Eric Fowke/Alamy

Head circumference measurements can help to assess brain growth.

◆ The Centers for Disease Control and Prevention provides complete sets of growth charts at its website: **cdc.gov/growthcharts/.**

◆ Reminder: Guidelines for assessing overweight and obesity were described in Chapter 8, p. 259.

Biochemical Data

Biochemical data provide information about protein-energy nutrition, vitamin and mineral status, fluid and electrolyte balance, and organ function. Most tests are based on analyses of blood or urine samples, which contain proteins, nutrients, and

TABLE 17-9 Use of Body Weight for Assessing Nutritional Risk

%IBW	%UBW	Nutritional Risk
80–89	85–95	Risk of mild malnutrition
70–79	75–84	Risk of moderate malnutrition
<70	<75	Risk of severe malnutrition

◆ Blood test results are reported in terms of either *plasma* or *serum* levels. *Plasma* is the yellow fluid that remains after cells are removed; it still contains clotting factors. *Serum* is the fluid remaining after both cells and clotting factors are removed.

◆ Fluid retention can result in lab results that are deceptively low. Dehydration may cause lab results to be deceptively high.

metabolites that reflect nutrition and health status. Table 17-10 lists and describes common blood tests ◆ that have nutritional implications. Laboratory tests relevant to specific diseases will be discussed in the chapters that follow.

Interpreting laboratory values can be challenging because a number of factors influence the test results. For example, serum protein values can be affected by fluid imbalances, ◆ pregnancy, medications, and exercise. Similarly, serum levels of vitamins and minerals are often poor indicators of nutrient deficiency because the values are affected by multiple variables; therefore, a variety of tests are generally needed to diagnose a nutrition problem. Taken together with other assessment data, however, laboratory test results help to present a clearer picture than is possible to obtain otherwise.

Plasma Proteins Plasma protein levels can help in the assessment of protein-energy status, but the levels may fluctuate for other reasons as well.[12] For example, plasma proteins are synthesized in the liver, so plasma concentrations can reflect liver function. Metabolic stress alters plasma protein levels, because the liver increases its synthesis of some plasma proteins and reduces the synthesis of others. Values may also be influenced by pregnancy, kidney function, zinc status, and some medications. Because plasma proteins are affected by so many factors, their values must be considered along with other data to evaluate nutrition status. The following paragraphs describe several of the plasma proteins commonly measured during illness.

◆ The term *half-life* defines the length of time that a substance remains in plasma. The albumin in plasma has a 3-week half-life, meaning that half of the amount circulating in plasma is degraded in a 3-week period.

Albumin Albumin is the most abundant plasma protein, and its levels are routinely monitored during illness. Although many medical conditions influence albumin, it is slow to reflect changes in nutrition status because of its large body pool and slow rate of degradation. ◆ In people with chronic PEM, albumin levels remain normal for long periods of time despite depletion of body proteins; levels fall only after prolonged malnutrition. Likewise, when malnutrition is treated, albumin concentrations increase slowly, so albumin is not a sensitive indicator of effective treatment.

HOW TO Estimate and Evaluate %IBW and %UBW

To estimate %IBW, compare an individual's current weight with a reasonable (ideal) weight from a BMI table or other appropriate reference:

$$\%\text{IBW} = \frac{\text{current weight}}{\text{ideal weight}} \times 100$$

For example, suppose you wish to calculate the %IBW for a woman who is 5 feet 8 inches tall and weighs 116 pounds. The midpoint of the healthy BMI range is approximately 22, so using a BMI table (as shown on the inside back cover of this book), you estimate that a reasonable weight for this woman would be about 144 pounds:

$$\%\text{IBW} = \frac{116}{144} \times 100 = 80.6\%$$

The woman in this example weighs about 80.6 percent of her ideal body weight. A look at Table 17-9 indicates that at 80.6 percent of IBW, she may be mildly malnourished. Keep in mind that the calculation of "ideal body weight" is somewhat arbitrary, because the BMI table and various other references provide a range of weights for individuals of a given height.

To estimate %UBW, compare a person's current weight with the weight that the person generally maintains:

$$\%\text{UBW} = \frac{\text{current weight}}{\text{usual weight}} \times 100$$

For example, if a man loses 32 pounds during illness and his usual weight is 180 pounds, his current weight would be 148 pounds. These values can be incorporated into the above equation:

$$\%\text{UBW} = \frac{148}{180} \times 100 = 82.2\%$$

The man in this example weighs 82.2 percent of his usual weight. A look at Table 17-9 shows that a person at 82 percent of UBW may be moderately malnourished.

TABLE 17-10 Routine Laboratory Tests with Nutritional Implications

This table presents a partial listing of some uses of commonly performed lab tests that have implications for nutritional problems.

Laboratory Test	Acceptable Range	Description
Hematology		
Red blood cell (RBC) count	Male: 4.3–5.7 million/μL Female: 3.8–5.1 million/μL	Number of RBC; aids anemia diagnosis.
Hemoglobin (Hb)	Male: 13.5–17.5 g/dL Female: 12.0–16.0 g/dL	Hemoglobin content of RBC; aids anemia diagnosis.
Hematocrit (Hct)	Male: 39–49% Female: 35–45%	Percentage RBC in total blood volume; aids anemia diagnosis.
Mean corpuscular volume (MCV)	80–100 fL	RBC size; helps to distinguish between microcytic and macrocytic anemias.
Mean corpuscular hemoglobin concentration (MCHC)	31–37% Hb/cell	Hb concentration within RBC; helps to distinguish iron-deficiency anemia.
White blood cell (WBC) count	4500–11,000 cells/μL	Number of WBC; general assessment of immunity.
Blood Chemistry		
Serum Proteins		
Total protein	6.4–8.3 g/dL	Protein levels are not specific to disease or highly sensitive; they can reflect body protein, illness or infections, changes in hydration or metabolism, pregnancy, or medications.
Albumin	3.4–4.8 g/dL	May reflect illness or PEM; slow to respond to improvement or worsening of disease.
Transferrin	200–400 mg/dL >60 yr: 180–380 mg/dL	May reflect illness, PEM, or iron deficiency; slightly more sensitive to changes than albumin.
Prealbumin (transthyretin)	10–40 mg/dL	May reflect illness or PEM; more responsive to health status changes than albumin or transferrin.
C-reactive protein	68–8200 ng/mL	Indicator of inflammation or disease.
Serum Enzymes		
Creatine kinase (CK)	Male: 38–174 U/L Female: 26–140 U/L	Different forms of CK are found in muscle, brain, and heart. High levels in blood may indicate heart attack, brain tissue damage, or skeletal muscle injury.
Lactate dehydrogenase (LDH)	208–378 U/L	LDH is found in many tissues. Specific types may be elevated after heart attack, lung damage, or liver disease.
Alkaline phosphatase	25–100 U/L	Found in many tissues; often measured to evaluate liver function.
Aspartate aminotransferase (AST, formerly SGOT)	10–30 U/L	Usually monitored to assess liver damage; elevated in most liver diseases. Levels are somewhat increased after muscle injury.
Alanine aminotransferase (ALT, formerly SGPT)	Male: 10–40 U/L Female: 7–35 U/L	Usually monitored to assess liver damage; elevated in most liver diseases. Levels are somewhat increased after muscle injury.
Serum Electrolytes		
Sodium	136–146 mEq/L	Helps to evaluate hydration status or neuromuscular, kidney, and adrenal functions.
Potassium	3.5–5.1 mEq/L	Helps to evaluate acid-base balance and kidney function; can detect potassium imbalances.
Chloride	98–106 mEq/L	Helps to evaluate hydration status and detect acid-base and electrolyte imbalances.
Other		
Glucose (fasting)[a]	74–106 mg/dL >60 yr: 80–115 mg/dL	Detects risk of glucose intolerance, diabetes mellitus, and hypoglycemia; helps to monitor diabetes treatment.
Glycosylated hemoglobin (HbA_{1c})	5.0–7.5% of Hb	Used to monitor long-term blood glucose control (approximately 1 to 3 months prior).
Blood urea nitrogen (BUN)	6–20 mg/dL	Primarily used to monitor kidney function; value is altered by liver failure, dehydration, or shock.
Uric acid	Male: 3.5–7.2 mg/dL Female: 2.6–6.0 mg/dL	Used for detecting gout or changes in kidney function; levels affected by age and diet; varies among different ethnic groups.
Creatinine (serum or plasma)	Male: 0.7–1.3 mg/dL Female: 0.6–1.1 mg/dL	Used to monitor renal function.

[a]Fasting glucose levels that repeatedly exceed 100 mg/dL suggest prediabetes.
NOTE: μL = microliter; dL = deciliter; fL = femtoliter; ng = nanogram; U/L = units per liter; mEq = milliequivalents.
SOURCE: L. Goldman and D. Ausiello, eds., *Cecil Textbook of Medicine* (Philadelphia: Saunders, 2004).

Transferrin Transferrin is an iron-transport protein, and its concentrations can respond to both iron deficiency and PEM. Transferrin levels rise as iron status worsens and fall as iron status improves, so using transferrin values to evaluate protein-energy status is difficult if an iron deficiency is also present. Transferrin is degraded more rapidly than albumin, ◆ but its levels change relatively slowly in response to nutrition therapy.

◆ Transferrin's half-life in plasma is approximately 8 to 10 days.

Prealbumin and Retinol-Binding Protein Levels of prealbumin (also called transthyretin) and retinol-binding protein decrease rapidly during PEM and respond quickly to improved protein intakes. ◆ Thus these proteins are more sensitive than albumin to changes in protein status. Like other plasma proteins, their usefulness in nutrition assessment is limited because they are affected by a number of different factors, including metabolic stress, zinc deficiency, and various medical conditions. Prealbumin and retinol-binding protein are more expensive to measure than albumin, so they are not routinely included during nutrition assessment.

◆ Half-lives of prealbumin and retinol-binding protein are 2 days and 12 hours, respectively.

Medical Tests and Procedures

Nutrient deficiencies often impair physiological functions, so medical tests and procedures are sometimes helpful for evaluating the physiological changes that accompany malnutrition or disease.[13] For example, both PEM and zinc deficiency can depress immunity, which can be assessed by testing the skin's response to antigens that ordinarily cause redness and swelling when immune function is adequate. Alterations in metabolic rate associated with disease or malnutrition can be assessed using indirect calorimetry (see Chapter 8). Muscle weakness due to **wasting**, or loss of muscle tissue, can be assessed by hand-grip strength. The chapters that follow provide additional examples of medical tests or procedures that suggest declines in physiological functioning.

Physical Examinations

As with other assessment methods, interpreting physical signs of malnutrition requires skill and clinical judgment. Most physical signs are nonspecific; they can reflect any of several nutrient deficiencies, as well as conditions unrelated to nutrition. For example, cracked lips may be caused by several B vitamin deficiencies but may also be caused by sunburn, windburn, or dehydration. Dietary and laboratory data are usually needed as additional evidence to confirm suspected nutrient deficiencies.

Mark Edwards/Peter Arnold, Inc.

Physical signs of malnutrition are often evident in parts of the body where the cells are replaced at a rapid rate.

Clinical Signs of Malnutrition Signs of malnutrition tend to appear most often in parts of the body where cell replacement occurs at a rapid rate, such as the hair, skin, and digestive tract (including the mouth and tongue). Table 17-11 lists some clinical signs of nutrient deficiencies. Many of the symptoms listed occur only in advanced stages of deficiency. The summary tables in Chapters 10 through 13 provide additional examples of the physical signs of nutrient imbalances.

Hydration State As mentioned previously, either fluid retention or dehydration may accompany some illnesses and may also result from the use of certain medications. Therefore, recognizing the patient's hydration state is necessary for the correct interpretation of blood tests and the body weight measurement.

Fluid retention (also called *edema*) can accompany malnutrition, infection, or injury. It can be caused by impaired blood circulation, and it frequently accompanies disorders of the heart and blood vessels, kidneys, liver, and lungs. Physical signs of fluid retention include weight gain, facial puffiness, swelling of limbs, abdominal distention, and tight-fitting shoes.

Dehydration can result from vomiting, diarrhea, sweating, fever, excessive urination, and skin injuries or burns (due to fluid loss through skin lesions). Dehydration risk is greatest in older adults, who have reduced thirst responses to water deprivation. Symptoms include thirst, dry skin or mouth, and reduced skin tension;

wasting: the gradual atrophy (loss) of body tissues; associated with protein-energy malnutrition or chronic illness.

TABLE 17-11 Clinical Signs of Nutrient Deficiencies

Body System	Acceptable	Signs of Malnutrition	Other Possible Causes
Hair	Shiny, firm in scalp	Dull, brittle, dry, loose; falls out (PEM); corkscrew hair (copper)	Excessive hair bleaching; hair loss from aging, chemotherapy, or radiation therapy
Eyes	Bright, clear pink membranes; adjust easily to light	Pale membranes (iron); spots, dryness, nightblindness (vitamin A); redness at corners of eyes (B vitamins)	Anemia, unrelated to nutrition; eye disorders; allergies
Lips	Smooth	Dry, cracked, or with sores in the corner of the lips (B vitamins)	Sunburn, windburn, excessive salivation from ill-fitting dentures or other disorders
Mouth and gums	Red tongue without swelling, normal sense of taste; teeth without caries; gums without bleeding, swelling, or pain	Smooth or magenta tongue (B vitamins), decreased taste sensations (zinc); swollen, bleeding gums (vitamin C)	Medications, periodontal disease (poor oral hygiene)
Skin	Smooth, firm, good color	Poor wound healing (PEM, vitamin C, zinc); dry, rough, lack of fat under skin (essential fatty acids, PEM, B vitamins); bruising, bleeding under skin (vitamins C and K)	Poor skin care, diabetes mellitus, aging, medications
Nails	Smooth, firm, pink	Ridged (PEM); spoon shaped, pale (iron)	
Other	—	Dementia, peripheral neuropathy (B vitamins); swollen glands at front of neck (PEM, iodine); bowed legs (vitamin D)	Disorders of aging (dementia), diabetes mellitus (peripheral neuropathy)

the urine color may be dark yellow or amber, and urine volume may be unusually low. The Case Study below can help you review the different components of a nutrition assessment.

CASE STUDY Nutrition Screening and Assessment

Elise Walden is an 85-year-old retired businesswoman who has been a widow for 10 years. She uses a walker and has poorly fitting dentures. She was recently admitted to the hospital with pneumonia and also has congestive heart failure and diabetes. She routinely takes several medications to control blood glucose, hypertension, and heart function, and, in addition to these, the physician ordered antibiotics to treat the pneumonia. During an initial nutrition screening, Mrs. Walden stated that she had been eating very poorly over the past two weeks. She said that she usually weighs about 125 pounds—a fact that was documented in her medical chart from a previous visit. Although she felt she was losing weight, she didn't know how much weight she may have lost or when she started losing weight. Upon admission to the hospital, Mrs. Walden weighed 110 pounds and was 5 feet, 3 inches tall. Her serum albumin level was 3.0 grams per deciliter. A physical exam revealed edema, and several other laboratory tests confirmed that she was retaining fluid. As a result of the nutrition screening, Mrs. Walden was referred to a registered dietitian for a complete nutrition assessment.

1. From the brief description provided, which items in Mrs. Walden's medical, social, and diet histories might alert the dietitian that this patient is at risk of malnutrition?
2. Identify a healthy body weight for Mrs. Walden, and calculate her %IBW and %UBW. What do the results reveal? What effect does fluid retention have on Mrs. Walden's weight?
3. How can fluid retention alter Mrs. Walden's serum protein levels? What physical symptoms may have suggested that she was retaining excess fluid?
4. What tools can be used to estimate Mrs. Walden's usual food intake? What medical, physical, and social factors are likely to affect her dietary intake?
5. Describe other types of assessment information the dietitian may need before developing a nutrition care plan.

IN SUMMARY

Nutrition assessments typically include historical information, anthropometric and biochemical data, medical tests and procedures, and physical examinations. Health care providers assess food intake using 24-hour recall interviews, food frequency questionnaires, food records, and direct observation. Anthropometric measurements help to evaluate growth patterns, overnutrition and undernutrition, and body composition. Biochemical analyses help in the assessment of nutrient imbalances but are influenced by various other medical problems. Physical examinations can help the assessor detect signs of nutrient deficiency and fluid imbalances.

Clinical Portfolio

- Describe the potential nutritional implications of these findings from a patient's medical, personal, and social histories: age 78, lives alone, recently lost spouse, uses a walker, has no natural teeth or dentures, has a history of hypertension and diabetes, uses medications that cause frequent urination.
- Calculate the %IBW and %UBW for a man who is 5 feet 11 inches tall with a current weight of 150 pounds and a usual body weight of 180 pounds. What additional information do you need to interpret the implications of his weight loss?
- Nurses often shoulder much of the responsibility for collecting food intake data for kcalorie counts because they typically deliver food trays and snacks and later retrieve them. Why is it important to verify and record both what the patient receives (foods and amounts) and the foods that remain uneaten? When might patients be enlisted in the collection of food intake data, and when might such a course be unwise?

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. In what ways can illnesses affect nutrition status? Contrast the roles of the different health care professionals in providing nutrition care. (pp. 589–591)
2. Give examples of the methods used for screening patients for malnutrition. Explain how nutrition screening differs from a complete nutrition assessment. (pp. 591–593)
3. Discuss each of the steps of the nutrition care process. (pp. 593–595)
4. Give examples of the types of information included in medical, social, and diet histories. (pp. 595–596)
5. Describe the methods of gathering food intake data, and indicate the advantages and disadvantages of each process. (pp. 596–599)
6. What types of anthropometric measurements are included in nutrition assessments? Explain how these measurements help in the evaluation of nutrition status. (pp. 599–601)
7. How do biochemical analyses help to assess nutrition status? Give examples. What confounding factors may influence the results of blood tests? (pp. 601–605)
8. Give examples of physical signs that can suggest malnutrition. Describe the signs and symptoms that can result from fluid retention and dehydration. (pp. 604–605)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 608.

1. Mr. Hom experiences loss of appetite, difficulty swallowing, and mouth pain as a consequence of illness. Mr. Hom is at risk of malnutrition due to:
   a. altered metabolism.
   b. reduced food intake.
   c. altered excretion of nutrients.
   d. altered digestion and absorption.
2. The central role of nurses in health care makes them well positioned for:
   a. calculating patients' nutrient needs.
   b. providing medical nutrition therapy.
   c. conducting complete nutrition assessments.
   d. identifying patients at risk for malnutrition.
3. Of the following data collected during a nutrition screening, which item does not place the person at risk for malnutrition?
   a. having a health problem that is frequently associated with PEM
   b. the use of prescription medications that affect nutrient needs
   c. residing with a spouse in a middle-income neighborhood
   d. a significant reduction in food intake over the past five or more days
4. The nutrition care process is a systematic approach for:
   a. identifying the nutrient content of foods.
   b. ordering special diets.
   c. conducting nutrition screening.
   d. meeting the nutrition needs of patients.
5. To conduct complete nutrition assessments, dietitians rely on several sources of information, which include all of the following *except:*
   a. nutrition care plans.
   b. body measurements.
   c. medical, medication, and social histories.
   d. biochemical data.
6. Which dietary assessment method does a health practitioner use to conduct a kcalorie count?
   a. 24-hour recall interview
   b. food frequency questionnaire
   c. food record
   d. direct observation
7. The %UBW of a person who weighs 135 pounds and has a usual body weight of 150 pounds is:
   a. 111 percent.
   b. 90 percent.
   c. 86 percent.
   d. 74 percent.
8. A malnourished patient has just begun to eat after days without significant amounts of food. Which of the following blood tests would change most quickly as the patient's nutrition status improves?
   a. albumin
   b. transferrin
   c. serum electrolytes
   d. retinol-binding protein
9. Which sign of PEM would be unlikely to show up in a physical examination?
   a. low plasma protein levels
   b. dull, brittle hair
   c. poor wound healing
   d. wasted appearance
10. Fluid retention may cause all of the following effects *except:*
    a. lab results that are deceptively high.
    b. facial puffiness.
    c. lab results that are deceptively low.
    d. tight-fitting shoes.

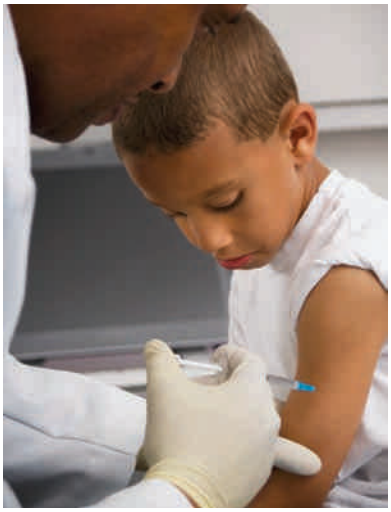
Nutrition and Immunity



© Matt Meadows/Peter Arnold, Inc.

The **immune system** protects the body by fighting infectious agents and eliminating abnormal or "worn-out" cells. Its elaborate network of interacting cells and molecules works to block invading organisms from entering the body and destroys those that do gain entry. Substances that elicit an immune response are called antigens; common examples include foreign proteins produced by bacteria, viruses, parasites, or fungi. Because the immune system can usually distinguish between the body's cells and proteins and those of invading organisms, the body's own tissues are protected.

This highlight introduces the immune system and its relationships to malnutrition and illness; the glossary below defines relevant terms. Later chapters examine some of the relationships between specific illnesses and immune processes. Some diseases result from inadequate immune responses, as when infections spread, causing sepsis (Chapter 22), or when malignant cells develop into tumors (Chapter 29). Other conditions, such as inflammatory bowel diseases (Chapter 24) and atherosclerosis (Chapter 27), result from **inflammation** (Chapter 22). Most of the time, however, the immune system's carefully orchestrated actions are quietly working to preserve health.

GLOSSARY

acute-phase proteins: plasma proteins released from the liver at the onset of acute infection. An example is **C-reactive protein,** which is considered one of the main indicators of severe infection and has antimicrobial effects.

adaptive immunity: immunity that is specific for particular antigens; it adapts to antigens in an individual's environment and is characterized by "memory" for particular antigens. Also called **acquired immunity.**

allergen: any substance that triggers an inappropriate immune response.

allergy: an excessive and inappropriate immune reaction to a harmless substance.

autoimmune diseases: diseases characterized by an attack of immune defenses on the body's own cells.

B cell: a lymphocyte that produces antibodies.

cell-mediated immunity: immunity conferred by T cells and macrophages.

complement: a group of plasma proteins that assist the activities of antibodies.

cytokines (SIGH-toe-kines): signaling proteins produced by the body's cells; those produced by white blood cells regulate immune cell development and immune responses.

humoral immunity: immunity conferred by B cells, which produce and release antibodies into body fluids.
- **humor** = fluid

hypersensitivity: immune responses that are excessive or inappropriate. One type of hypersensitivity is *allergy.*

immune system: the body's defense system against foreign substances.

immunoglobulins (IM-you-no-GLOB-you-linz): large globular proteins produced by B cells that function as antibodies.

inflammation: a nonspecific response to injury or infection; a type of innate immune response.

innate immunity: immunity that is present at birth, unchanging throughout life, and nonspecific for particular antigens; also called **natural immunity.**

leukocytes: blood cells that function in immunity; also called **white blood cells.**

lymph (LIMF): the body fluid carried in lymphatic vessels; lymph is collected from the extracellular fluids of body tissues and ultimately transported to the bloodstream.

lymphatic vessels: vessels through which lymph travels.

lymphocytes (LIM-foe-sites): white blood cells that recognize specific antigens and therefore function in adaptive immunity; include *T cells* and *B cells.*

lymphoid tissues: tissues that have roles in immunity.

lysozyme (LYE-so-zyme): an enzyme with antibacterial properties; found in immune cells and body secretions such as tears, saliva, and sweat.

macrophages (MAK-roe-fay-jez): monocytes that have left circulation and settled in a tissue, where they serve as scavengers and activate the immune response.

monocytes (MON-oh-sites): cells released from the bone marrow that move into tissues and mature into macrophages.

natural killer cells: lymphocytes that confer nonspecific immunity by destroying a wide array of viruses and tumor cells.

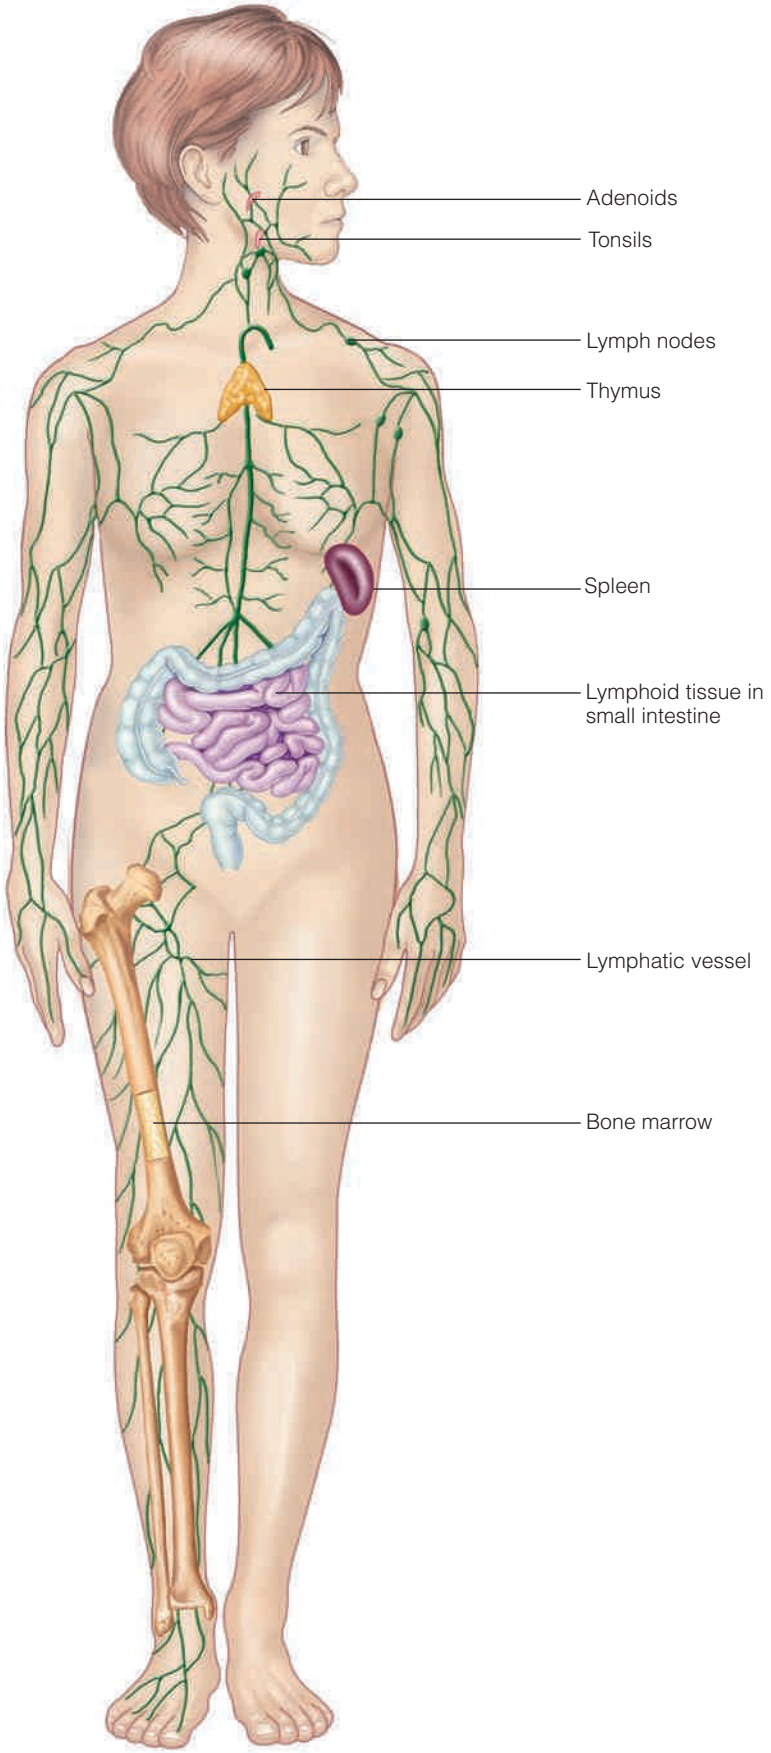
neutrophils (NEW-tro-fills): the most common type of white blood cell. Neutrophils destroy antigens by phagocytosis.

phagocytes (FAG-oh-sites): white blood cells (primarily neutrophils and macrophages) that have the ability to engulf and destroy antigens.
- **phagein** = to eat

phagocytosis (FAG-oh-sigh-TOE-sis): the process by which phagocytes engulf and destroy antigens.

T cell: a lymphocyte that attacks antigens; functions in cell-mediated immunity.

FIGURE H17-1 The Lymphatic System



Tissues of the Immune System

The immune system resides in no single organ, but depends on the physical and chemical interactions of a loosely organized network of cells and tissues scattered throughout the body.[1] The tissues and organs involved in immunity are collectively known as the lymphatic system (see Figure H17-1). **Lymphoid tissues** include the thymus gland and bone marrow (where **lymphocytes** are made), and the spleen, tonsils, adenoids, and lymph nodes (where foreign materials and debris are filtered out and discarded). Additional lymphoid tissue is dispersed in various locations throughout the body—especially within the mucosal linings of the gastrointestinal tract, the respiratory tract, and the genitourinary tract, where antigens are most likely to enter the body.

The cells active in immunity are the **leukocytes** (commonly known as **white blood cells**) and several types of accessory cells, as described in Table H17-1 and discussed in the following pages. These cells act by releasing chemicals such as enzymes, prostaglandins, and histamine, as well as proteins called **cytokines** that bind to receptors on target cells. White blood cells travel between the tissues and blood in **lymph,** a body fluid carried by the **lymphatic vessels.** Lymph is collected from the extracellular fluids that bathe tissues and is eventually transported to the bloodstream.

Examples of Innate Immunity

The immune protection present at birth is called **innate,** or **natural, immunity.** Innate immunity is nonspecific—it deters and destroys a wide range of pathogens. Nonspecific defenses include physical barriers to invading organisms, actions of defensive proteins, and activities of phagocytes and natural killer cells.

Physical Barriers to Infection

The body's first line of defense—the skin and mucous membranes—prevents the entry of infectious agents, which might otherwise gain easy access to tissues and blood. Skin not only provides an impenetrable physical barrier but also contains its own lymphoid tissue and a variety of immune cells interspersed in its outer layers. Mucous membranes lining the gastrointestinal, respiratory, and genitourinary tracts also act as barriers to infection: the mucous layers of these tissues trap microorganisms and prevent them from attaching to tissue surfaces.[2]

Microbes that arrive in the stomach face possible destruction from acidic gastric juices and enzymes. Those that survive enter the small intestine, where digestive secretions and

TABLE H17-1 Cells of the Immune System

White Blood Cells	Cell Type	Function
Lymphocytes	T cells	Activate macrophages Assist B cells Destroy virally infected cells
	B cells	Produce and secrete antibodies
	Natural killer cells	Destroy virally infected cells
Phagocytes	Monocytes/macrophages[a]	Present antigen fragments to T cells Engulf pathogens and cellular debris
	Neutrophils	Engulf pathogens and cellular debris
	Eosinophils	Release proteins that damage parasites Suppress inflammatory reactions
Accessory Cells	**Cell Type**	**Function**
Inflammatory mediators	Basophils	Release mediators that regulate inflammation
	Mast cells	Release mediators that regulate inflammation
	Platelets	Have primary role in blood clotting Release mediators that regulate inflammation

[a]Monocytes circulate in blood and become macrophages after they enter tissues.

specialized cells, antibodies, and lymphoid tissue protect against infection. The large intestine also contains defensive cells and antibodies, as well as stable bacterial populations that help to maintain mucosal tissue and create a hostile environment for invasive bacteria.[3]

Defensive Proteins

Proteins contribute to nonspecific immune defenses by serving as enzymes or signaling molecules. The liver releases **acute-phase proteins** in response to trauma, infection, or inflammation. Some acute-phase proteins, such as **C-reactive protein,** have antimicrobial activities that destroy some types of bacteria. C-reactive protein is considered a "marker" of acute inflammation and becomes elevated only when the body is fighting disease. Other acute-phase proteins include **complement,** a group of about 25 plasma proteins, so named because the proteins "complement" the activities of antibodies. When an antibody interacts with an antigen, a complex is formed that starts a series of reactions between the complement proteins. These actions may render microbes more susceptible to phagocytosis (described later), puncture a target cell's membrane, or help rid the body of antigen-antibody complexes. Another protein, **lysozyme,** attacks bacteria by breaking down carbohydrates on bacterial cell walls, causing the bacteria to burst.

Phagocytes

Upon entering the body, pathogens may encounter **phagocytes,** the scavenger cells of the immune system. Phagocytes engulf and digest bacteria, cellular debris (from damaged cells), and foreign particles in a process called **phagocytosis.** Phagocytes are attracted to their targets by the presence of common microbial products, complement fragments, or chemical signals produced by cells. They pull in their prey by extending pseudopods ("false feet") and then douse it with a mix of potent chemicals that include hydrolytic enzymes, lysozyme, and free radicals.

The two main types of phagocytes are neutrophils and macrophages. **Neutrophils** are the predominant leukocytes in the blood, making up about 50 to 65 percent of the total. They also have the shortest life spans, surviving only a day or two after they are released from bone marrow. Neutrophils migrate into tissues in response to injury or infection and accumulate in large numbers during the inflammatory process (discussed in Chapter 22). **Macrophages** are initially released from bone marrow as **monocytes;** after about a day in circulation, a monocyte migrates into one particular tissue, where it develops into a macrophage and survives for several months or longer. Each tissue has its own resident macrophages, and although their names may vary, they have similar functions in all tissues in which they reside. Examples of tissue macrophages include the Langerhans cells in the skin and the Kupffer cells in the liver.

Macrophages move and kill bacteria more slowly than neutrophils, but they are larger and can engulf larger targets, such as the body's dead and damaged cells. They also have the additional ability to display fragments of engulfed antigens on their cell surfaces for lymphocytes to recognize. This action triggers the immune responses of the lymphocytes, as described in a later section.

© Dennis Kunkel/Visuals Unlimited

A macrophage extends pseudopods to pull in and engulf bacteria.

Natural Killer Cells

Natural killer cells, which are members of the lymphocyte family, recognize and destroy virus-infected cells and tumor cells. These killer cells produce pore-forming proteins (called perforins) that puncture their target cells' membranes. The killer cells then transfer destructive enzymes into the damaged cells, further destroying their structures and encouraging self-destruction. Finally, phagocytes arrive at the scene to remove fragments left behind by the newly destroyed cells. The next section discusses the other members of the lymphocyte family, the B cells and T cells, which have critical roles in adaptive immunity.

© Bill Beatty/Visuals Unlimited

The rash that appears after contact with poison oak is an example of skin hypersensitivity.

Examples of Adaptive Immunity

In **adaptive,** or **acquired, immunity,** immune cells and proteins recognize *specific* pathogens as being foreign. Each **B cell** or **T cell** generates antibodies or receptors that can recognize only one type of antigen. Once activated, a lymphocyte produces other cells just like itself so that the newly formed army can attack the invading antigens and combat the infection. The lymphocytes are able to recognize a huge and diverse number of foreign molecules. Some of the lymphocytes serve as "memory cells," which survive for many years, enabling the immune system to respond rapidly if the same infection recurs.

B Cells

The B cells confer **humoral immunity,** so named because the cells' secretions, not the cells themselves, mount the defense within bodily fluids. B cells respond to antigens by producing antibodies that travel in the blood or tissue fluids to the site of infection. Antibodies, also known as **immunoglobulins,** are literally large globular proteins that provide immune protection. Each B cell expresses thousands of identical antibodies on its surface. Once an antigen binds, the B cell multiplies. Its daughter cells produce large numbers of the same antibody and secrete them into the surrounding fluids. The free antibodies then attach to the surfaces of antigens to neutralize them or make them an easy target for attack by phagocytes. The antibodies can also bind to viral proteins to prevent viruses from entering cells.

T Cells

T cells participate in **cell-mediated immunity,** so named because the cells themselves direct an immune response. A T cell has thousands of identical receptors on its cell surface (called T-cell receptors) that can recognize only one type of antigen. The antigens are displayed on the surfaces of antigen-presenting cells, specialized cells designed for this task (such as macrophages and B cells). After a *helper T cell* binds to an antigen fragment on an antigen-presenting cell, it recruits a *cytotoxic T cell* to the region to attack and destroy the local antigens. The actions of cytotoxic T cells are similar to those of natural killer cells: they perforate cell membranes and deliver powerful chemicals that eventually lead to a cell's destruction. Helper T cells can also activate B cells to produce antibodies and can activate macrophages to destroy the pathogens they have engulfed.

Undesirable Effects of Immunity

The body's immune function can sometimes create problems. Exaggerated or inappropriate immune reactions, referred to as **hypersensitivity,** can lead to discomfort or illness. **Allergy** is an example of an exaggerated response to an **allergen,** a harmless protein that may be eaten or inhaled. (Food allergy was introduced in Chapter 15 and is discussed further in Highlight 25.) As another example, the immune complexes formed from antigens and antibodies can cause damage to tissues if not readily cleared by phagocytes. **Autoimmune diseases,** including such familiar diseases as type 1 diabetes mellitus and pernicious anemia, develop when immune responses are mounted against the body's own cells. Although the effects of the immune system are lifesaving when directed at harmful pathogens, they can be life threatening when turned against the body.

Malnutrition and Immunity

Malnutrition affects all aspects of immunity, including both innate and adaptive immune defenses. For example, both PEM and vitamin A deficiency can result in damage to skin and mucous membranes, allowing microorganisms easier entry into the body. Deficiencies of protein and various micronutrients can affect the synthesis of hydrolytic enzymes, complement, antibodies, and other proteins important for immune function. Cell-mediated immunity is impaired in numerous ways by both PEM and zinc deficiencies.[4]

Because PEM is usually associated with multiple micronutrient deficiencies, it has been difficult for researchers to separate out

the influences of individual nutrients. Nevertheless, zinc, iron, and vitamin A deficiencies are among the predominant micronutrient deficiencies worldwide, and a large body of research has demonstrated that each has a strong, independent influence on immunity. Notably, supplementation of various micronutrients (especially zinc and vitamin A) in malnourished populations has been found to reduce the incidence and severity of illness.[5]

Malnutrition and Infection

Because malnutrition impairs immune function in numerous ways, it is frequently associated with an increased risk of infection. In addition, an infection itself can worsen malnutrition (as described in the following section). The result is a downward spiral in immunity and overall health. Malnourished populations have higher-than-normal incidences of infectious diseases such as measles, malaria, acute respiratory infections, diarrheal diseases, and tuberculosis.[6] These diseases are major causes of morbidity and mortality in developing countries.

Infection and Nutrition Status

As mentioned, the effects of infection can be detrimental to nutrition status.[7] Anorexia often develops and is worse when an infection is severe, resulting in weight loss, negative nitrogen balance, and delayed growth and healing. Intestinal infections can cause nutrient malabsorption, atrophy of intestinal tissue, substantial blood loss, and diarrhea. Furthermore, infections generally stimulate metabolic processes, raising metabolic rate and nutrient needs as well. Chapter 22 delves further into the consequences of severe infection and discusses the nutrient needs of individuals who suffer from these conditions.

Nutrition in the Clinical Setting

When working with patients, remember to establish a caring environment. Use familiar language, maintain eye contact, and be a good listener. Showing your interest can go a long way toward winning a patient's trust. A patient may greet even an ideal dietary plan with resentment and bitterness, for it may restrict favorite foods and make it more difficult to forget about an illness. When their interactions with health practitioners are positive and encouraging, individuals are more likely to make the dietary changes that benefit health.

CHAPTER 18

Nutrition Intervention

CHAPTER OUTLINE

Implementing Nutrition Care • Documenting Nutrition Care • Approaches to Nutrition Care

Determining Energy Requirements

Dietary Modifications • Modified Diets • Alternative Feeding Routes • Nothing by Mouth (NPO)

Foodservice • Menu Planning • Food Selection • Food Preparation and Delivery • Food Safety • Improving Food Intake

HIGHLIGHT 18 Foodborne Illnesses

Chapter 17 discussed the interactions between illness and nutrition status and described the process of nutrition assessment. The results of the nutrition assessment allow dietitians to diagnose actual and potential nutrition problems. ◆ This chapter explains how dietitians and other health care professionals address nutrition problems and provide nutrition care. Ensuring that dietary needs are met is a key part of this process, so the chapter also describes methods for estimating energy requirements, common dietary modifications, and the foodservice provided in health care facilities.

◆ Nutrition diagnoses were discussed in Chapter 17, p. 594.

Implementing Nutrition Care

After formulating nutrition diagnoses, the dietitian determines the appropriate nutrition interventions. Table 18-1 on p. 616 shows how nutrition interventions are categorized.[1] Most nutrition interventions include a **nutrition prescription,** which provides specific dietary recommendations regarding food, nutrient, or energy intake or feeding method. Many interventions include nutrition education and counseling, which provide the knowledge, skills, and motivation that enable the patient to make necessary dietary and lifestyle changes. Some nutrition interventions require coordination with a number of other health professionals or facilities.

A nutrition intervention always includes two interrelated components: the planning process and the plan's implementation.[2] As Table 18-2 on p. 616 shows, the planning phase includes prioritizing the nutrition problems that were identified, determining their proper treatments, and setting goals. Implementing the plan involves communication with the patient, caregiver, and colleagues; carrying out the necessary treatments; and adjusting the plan when necessary.

Documenting Nutrition Care

Each step of the nutrition care process must be documented in the patient's medical record. The entries should be as succinct as possible so that they can be easily read

nutrition prescription: specific dietary recommendations related to food, nutrient, or energy intake or feeding method.

TABLE 18-1 Examples of Nutrition Interventions

Intervention	Examples
Food and/or nutrient delivery	Providing appropriate meals, snacks, and dietary supplements
	Providing specialized nutrition support (tube and intravenous feedings)
	Determining need for feeding assistance or adjustment in feeding environment
	Managing nutrition-related medication problems
Nutrition education	Providing basic nutrition-related instruction
	Providing in-depth training to increase dietary knowledge or skills
Nutrition counseling	Helping individual set priorities and establish goals
	Motivating individual to change behaviors
	Solving problems that interfere with the nutrition care plan
Coordination of nutrition care	Providing referrals or consulting other health professionals or agencies that can assist with treatment
	Organizing treatments that involve other health professionals or health care facilities
	Arranging transfer of nutrition care to another professional or location

TABLE 18-2 Elements of Nutrition Interventions

Planning Nutrition Care

- Prioritizing nutrition diagnoses
- Consulting dietetics practice guidelines
- Reviewing the policies of the health care facility
- Determining specific dietary recommendations
- Conferring with the patient or caregivers
- Establishing goals and expected outcomes

Implementing the Nutrition Care Plan

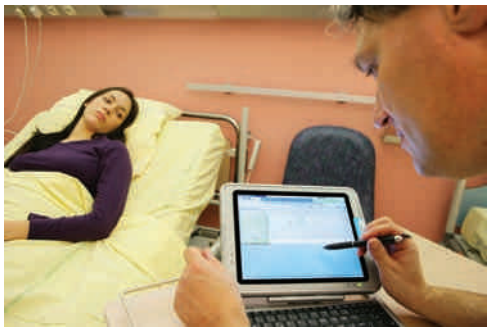
- Documenting the nutrition care plan in the medical record
- Discussing the nutrition care plan with the patient or caregivers
- Individualizing treatment as warranted
- Continuing data collection and documentation
- Revising the nutrition care plan as warranted

SOURCE: American Dietetic Association, *Nutrition Diagnosis and Intervention: Standardized Language for the Nutrition Care Process* (Chicago: American Dietetic Association, 2007).

and quickly understood by the other members of the health care team. In addition, electronic (computerized) data systems, which have been widely adopted in the past decade, have standardized templates that require concise language. Before making entries in patients' medical records, health care professionals need to learn the particular charting methods preferred by their medical facility. The following sections describe some popular formats used for documenting nutrition care.[3]

ADIME Format The ADIME format closely reflects the steps of the nutrition care process. Each letter represents one of the steps: *A*ssessment, *D*iagnosis, *I*ntervention, *M*onitoring, and *E*valuation. Using this format, the nutrition care plan would be recorded as follows:

- *Assessment.* The assessment section summarizes relevant assessment results, such as the medical problem, historical information, height, weight, BMI, laboratory test results, and relevant symptoms.
- *Diagnosis.* In the diagnosis section, the nutrition diagnoses are listed and prioritized.
- *Intervention.* The intervention section describes treatment goals and expected outcomes, specific interventions, and the patient's responses to nutrition care.
- *Monitoring and evaluation.* The monitoring and evaluation sections record the patient's progress, changes in the patient's condition, and adjustments in the care plan.



© Furgolle/Image Point FR/Corbis

Many health care facilities maintain computerized medical records, which have standardized templates that require concise language.

SOAP Format The SOAP format is the oldest method used for documenting nutrition care and is still in popular use. The letters refer to *S*ubjective, *O*bjective, *A*ssessment, and the *P*lan for care, and the nutrition care plan would be documented as follows:

- *Subjective.* The "Subjective" section includes assessment data obtained from the medical record and an interview with the patient or caregiver, including the chief medical problem and relevant symptoms.
- *Objective.* The "Objective" section includes objective assessment data, such as the results of biochemical analyses, anthropometric tests, medical procedures, and physical examinations.
- *Assessment.* A brief evaluation of the subjective and objective data and the nutrition diagnoses are presented in the "Assessment" section.
- *Plan.* Under "Plan" are recommendations that can help solve the problem, including the nutrition prescription, plans for nutrition education and counseling, and referrals to other professionals or agencies.

Figure 18-1 on p. 618 shows an example of a SOAP note, although there are many possible variations.

PES Statement The PES statement, introduced in Chapter 17 (see p. 594), is the general structure used for formatting nutrition diagnoses and can be used in any formatting style. The PES statement is so named because it includes the *P*roblem, *E*tiology or cause of the problem, and the *S*igns and symptoms that provide evidence for the problem. The SOAP note in Figure 18-1 includes two PES statements.

Approaches to Nutrition Care

A nutrition care plan often involves significant dietary modifications. To ensure better compliance, the plan needs to be compatible with the desires and abilities of the person it is designed to help. The challenge is greater if dietary changes are required for extended periods.

Long-Term Dietary Intervention When long-term changes are necessary, a care plan must take into account a person's current food habits, lifestyle, and degree of motivation. Behavior change is a process that occurs in stages; therefore, more than one consultation is usually necessary. The following approaches may be helpful in implementing long-term dietary changes:[4]

- *Determine the individual's readiness for change.* Some people have little desire to change their dietary behaviors, and even individuals who are willing may not be fully prepared to take the necessary steps. The health practitioner needs to consider a patient's readiness to adopt new dietary behaviors before attempting to implement an ambitious care plan.
- *Emphasize what to eat, rather than what not to eat.* Emphasizing foods to include in the diet, rather than those to restrict, can make dietary changes

FIGURE 18-1 Example of a SOAP Note

SOAP NOTE

Patient Name: James Steiner **Date:** Sept. 15, 2008

Age: 58 **Gender:** Male **Medical diagnosis:** Hypercholesterolemia

Subjective:

Mr. Steiner recently learned of his hypercholesterolemia; wants to try dietary/lifestyle changes to reduce need for the medication. Reports frequent snacking and little time for exercise. Willing to attempt weight loss.

Objective:

Total cholesterol: 288 mg/dl
LDL-C: 214 mg/dl; HDL-C: 48 mg/dl
Triglycerides: 132 mg/dl
Height: 6'1"; Weight: 268 lb.
BMI: 35.4
Waist circumference: 45"

Assessment:

Abdominal obesity; analysis reveals intake of approximately 4200 kcal per day, about 1500 kcal above estimated needs; snack food choices are high in kcal and saturated fat.
Nutrition Diagnoses:
1. Obesity related to excess energy intake of 1500 kcal/day and physical inactivity as evidenced by BMI of 35.4
2. Undesirable food choices related to inadequate access to appropriate foods at work as evidenced by elevated body weight and LDL cholesterol

Plan:

Goal: 15 lb. weight loss over next 6 months.
Mr. Steiner to start 45-minute walking program, evenings.
Nutrition prescription: reduction of food intake to about 2400 kcal per day with about 30% kcal from fat, and 7% of kcal from saturated fat.
Initial education: appropriate food portions, low-kcal foods and snacks, food sources of saturated fat, pre-planning lunches at work.
Referral: Heart-healthy workshop on Sept. 22 (one week); Mr. Steiner to attend with wife.
Follow-up visit: Oct 15 (one month); Mr. Steiner to keep 3-day food record before visit; will identify appropriate food portions and between-meal snacks.

Form completed by: Genevieve Johnson, MPH, R.D **Position:** Dietitian, Nutrition Services

more appealing. For example, encouraging additional fruits and vegetables is a more attractive message than telling the patient to restrict butter, cream sauces, and ice cream.

- *Suggest only one or two changes at a time.* People are more likely to adopt a dietary plan that does not deviate too much from their usual diet. If they succeed in adopting one or two changes, they are more likely to stick to the plan and be open to additional suggestions. Stricter plans may yield quicker results but are useful only for highly motivated people.

Nutrition Education Nutrition education allows patients to learn about the dietary factors that affect their particular medical condition. Ideally, this knowledge can motivate them to change their diet and lifestyle in order to improve their health status.

A nutrition education program should be tailored to a person's age, level of literacy, and cultural background. Learning style must also be considered: some people learn best by discussion supplemented with written materials, whereas others prefer visual examples, such as food models and measuring devices.[5] Information is provided in either one-on-one sessions or group discussions. The meeting should include an assessment of the person's understanding of the material and commitment to making changes. Follow-up sessions can reveal whether the person has

successfully adopted a dietary plan. For example, a dietitian who counsels a woman who is lactose intolerant and hesitant to use milk products might proceed as follows:

- The dietitian provides sample menus of a nutritionally adequate diet that limits milk and milk products. Together, the dietitian and the woman design menus that consider her food preferences.
- The dietitian describes the types and amounts of milk products that are unlikely to cause symptoms and explains how to gradually incorporate these foods into the diet.
- Using diet analysis software, the dietitian demonstrates how altering intakes of calcium-containing foods changes a meal's calcium content.
- The dietitian explains how to use the Daily Values on food labels to estimate the calcium content of packaged foods.
- The dietitian provides information about the advantages and disadvantages of different calcium supplements.
- The dietitian assesses the woman's understanding by having her identify nonmilk products that are high in calcium.

Ideally, the dietitian would be able to monitor the woman's progress in a subsequent counseling session.

Follow-up Care For optimal success, dietitians should try to monitor the patient's progress and periodically evaluate the effectiveness of the nutrition care plan. Doing so usually involves comparing relevant outcome measures (such as the results of blood tests) with initial values and meeting with the patient to learn whether the plan has been satisfactory from the patient's point of view. Such follow-up efforts can reveal whether the care plan needs to be revised, as is often the case when a person's situation changes. For example, after a pregnant woman delivers her baby, she may need instructions on how to feed her infant or how to modify her diet to support lactation (if she is breastfeeding) so that she can return to a healthy body weight. If a follow-up meeting with a dietitian is not possible, a dietetic technician or other qualified health practitioner should provide additional guidance and education.

Dietary counseling requires sensitivity to cultural orientation, educational background, and motivation for change.

IN SUMMARY

Nutrition interventions are designed to correct the nutrition problems associated with illness. An intervention should take into account a person's food habits, lifestyle, cultural orientation, educational background, and degree of motivation. Each step of nutrition care should be clearly documented in the medical record; the ADIME and SOAP formats are popular styles of documentation. Nutrition education may be provided in an individual counseling session or group workshop. Nutrition care can be evaluated by reviewing relevant outcome measures of health status and determining the patient's understanding and acceptance of the intervention.

Determining Energy Requirements

To determine energy requirements for hospital patients, clinicians typically estimate the resting metabolic rate (RMR), and then adjust the RMR value with "stress factors" that account for medical problems and, in some cases, medical treatments. In ambulatory patients, a factor for activity level may also be necessary. The standard clinical procedure for determining RMR is indirect calorimetry, which measures oxygen consumption and carbon dioxide production (thereby determining kcalories burned) during a period of rest.[6] The procedure is labor intensive, so clinicians more often use

Richard T. Nowitz/Photo Researchers, Inc.

Indirect calorimetry is performed using equipment that analyzes the oxygen and carbon dioxide content of inhaled and exhaled air.

TABLE 18-3 Selected Equations for Estimating Resting Metabolic Rate (RMR)

Harris-Benedict[a]

Women:

RMR = 655.1 + [9.563 × weight (kg)] + [1.85 × height (cm)] − [4.676 × age (years)]

Men:

RMR = 66.5 + [13.75 × weight (kg)] + [5.003 × height (cm)] − [6.755 × age (years)]

Mifflin-St. Jeor

Women:

RMR = [9.99 × weight (kg)] + [6.25 × height (cm)] − [4.92 × age (years)] − 161

Men:

RMR = [9.99 × weight (kg)] + [6.25 × height (cm)] − [4.92 × age (years)] + 5

WHO/FAO/UNU[a]

Girls and women (age range, years):

10–18: RMR = [7.4 × weight (kg)] + [482 × height (m)] + 217

18–30: RMR = [13.3 × weight (kg)] + [334 × height (m)] + 35

30–60: RMR = [8.7 × weight (kg)] − [25 × height (m)] + 865

>60: RMR = [9.2 × weight (kg)] + [637 × height (m)] − 302

Men and boys (age range, years):

10–18: RMR = [16.6 × weight (kg)] + [77 × height (m)] + 572

18–30: RMR = [15.4 × weight (kg)] − [27 × height (m)] + 717

30–60: RMR = [11.3 × weight (kg)] + [16 × height (m)] + 901

>60: RMR = [8.8 × weight (kg)] + [1128 × height (m)] − 1071

[a]Although these equations are sometimes used for estimating basal metabolic rate (BMR), they were derived from data measured during resting conditions in most cases.

SOURCES: M. D. Mifflin and coauthors, A new predictive equation for resting energy expenditure in healthy individuals, *American Journal of Clinical Nutrition* 51 (1990): 241–247; World Health Organization, *Energy and Protein Requirements: Report of a Joint FAOAVHO/UNU Expert Consultation* (Geneva: World Health Organization, 1985); J. A. Harris and F. G. Benedict, A biometric study of human basal metabolism, *Proceedings of the National Academy of Sciences USA* 4 (1918): 370–373.

predictive equations that yield similar results. Table 18-3 lists several RMR equations in common use; the "How to" on p. 621 presents an example of this method.

In overweight and obese individuals who are not critically ill, the Mifflin-St. Jeor equation has been found to yield the most accurate results.[7] In other equations, adjusted body weights are sometimes used in place of actual body weights in an attempt to improve accuracy. For example, some research studies have suggested that the Harris-Benedict equation may be more appropriate for obese patients if the body weight used in the equation falls between an estimated ideal weight and the patient's actual weight. ◆ Other studies, however, have been unable to confirm the usefulness of body weight adjustments in predictive equations.[8]

◆ A method sometimes used for adjusting body weight:
Adjusted body weight = ideal weight + 0.25 (actual weight − ideal weight)

Critical care patients may have energy needs that are considerably higher than normal due to fever, mechanical ventilation, restlessness, or the presence of open wounds. Patients who are critically ill are usually bedridden and inactive, however, so the energy needed for physical activity is minimal. Energy requirements for critical care patients are discussed further in Chapter 22.

HOW TO Estimate the Energy Requirements of a Hospital Patient

To determine the energy requirements of a hospital patient, the health practitioner calculates the patient's resting metabolic rate (RMR) and then applies a "stress factor" to accommodate the additional energy needs imposed by illness. The stress factor 1.25 has been shown to be reasonably accurate for many hospitalized patients; other examples are listed in Table 22-2 on p. 713.

The following example uses the WHO/FAO/UNU equation (shown in Table 18-3) and the stress factor 1.25 to determine the energy needs of a 54-year-old female patient who is 5 feet 3 inches tall, weighs 115 pounds, and is confined to bed.

Step 1: The patient's weight and height are converted to the units used in the equation:

$$\text{Weight in kilograms} = 115 \text{ lb} \div 2.2 \text{ lb/kg} = 52.3 \text{ kg}$$
$$\text{Height in meters} = 63 \text{ in.} \times 0.0254 \text{ m/in.} = 1.6 \text{ m}$$

Step 2: Using the WHO/FAO/UNU equation for estimating the RMR in women between 30 and 60 years old:

$$\begin{aligned}\text{RMR} &= [8.7 \times \text{weight (kg)}] - [25 \times \text{height (m)}] + 865 \\ &= (8.7 \times 52.3) - (25 \times 1.6) + 865 \\ &= 455 - 40 + 865 = 1280 \text{ kcal}\end{aligned}$$

Step 3: The RMR value is multiplied by the appropriate stress factor:

$$\text{RMR} \times \text{stress factor} = 1280 \times 1.25 = 1600 \text{ kcal}$$

Thus, an appropriate energy intake for this patient would be approximately 1600 kcal. Her weight should be monitored to determine if her actual needs are higher or lower.

For a patient who is not confined to bed, an additional activity factor can be applied to accommodate the extra energy needs. For example, if the patient in the example begins limited activity while in the hospital, an activity factor of 1.2 can be multiplied by the results obtained in Step 3:

$$1600 \times \text{activity factor} = 1600 \times 1.2 = 1920 \text{ kcal}$$

The activity factor for a hospitalized patient often falls between 1.1 and 1.4, and it is likely to change as the patient's condition improves.

IN SUMMARY

Energy requirements are typically estimated by multiplying a person's resting metabolic rate (RMR) by factors that account for the medical condition, medical treatments, and activity level. The RMR value can be obtained from indirect calorimetry or a predictive equation. Energy needs of critical care patients can be increased by fever, mechanical ventilation, restlessness, and open wounds.

Dietary Modifications

During illness, many patients can meet energy and nutrient needs by following a **standard diet.** Other patients may require a **modified diet,** which is altered by changing food consistency or nutrient content or by including or eliminating specific foods. If a patient's medical condition makes it difficult to meet nutrient needs orally, two options remain: *tube feedings* and *intravenous feedings.* This section introduces the use of modified diets and alternative feeding routes in clinical care. Later chapters describe other types of modified diets and additional dietary strategies for treating nutritional problems.

Modified Diets

Table 18-4 on p. 622 lists examples of modified diets that are often prescribed during illness.[9] Diets with altered texture and consistency are often prescribed for individuals with chewing and swallowing difficulties. Diets with modified nutrient or food content are frequently used to relieve disease symptoms or reduce the risk of developing complications. Some patients may have several medical problems and need a number of dietary changes. Keep in mind that modified diets should be adjusted to satisfy individual preferences and tolerances and may also need to be altered as a patient's condition changes.

standard diet: a diet that includes all foods and meets the nutrient needs of healthy people; also called a *regular diet.*

modified diet: a diet that is altered by changing food consistency or nutrient content or by including or eliminating specific foods; also called a *therapeutic diet.*

TABLE 18-4 Examples of Modified Diets

Type of Diet	Description of Diet	Appropriate Uses
Modified Texture and Consistency		
Mechanically altered diets	Contain foods that are modified in texture. Pureed diets include only pureed foods; mechanical soft diets may include solid foods that are mashed, minced, ground, or soft.	Pureed diets are used for people with swallowing difficulty, poor lip and tongue control, or oral hypersensitivity. Mechanical soft diets are appropriate for people with limited chewing ability or certain swallowing impairments.
Blenderized liquid diet	Contains fluids and foods that are blenderized to liquid form.	For people who cannot chew, swallow easily, or tolerate solid foods.
Clear liquid diet	Contains clear fluids or foods that are liquid at room temperature and leave minimal residue in the colon.	For preparation for bowel surgery or colonoscopy, for acute GI disturbances (such as after GI surgeries), or as a transition diet after intravenous feeding. For short-term use only.
Therapeutic Diets		
Fat-restricted diet	Restricts fat to low (<50 g/day) or very low (<25 g/day) levels in the diet.	For people who have certain malabsorptive disorders or symptoms of diarrhea, flatulence, or steatorrhea (fecal fat) resulting from dietary fat intolerance.
Fiber-restricted diet	Restricts fiber to low levels in the diet (<10 g/day).	For acute phases of intestinal disorders or to reduce fecal output before surgery. Not recommended for long-term use.
Sodium-restricted diet	Restricts sodium; degree of restriction depends on symptoms and disease severity.	To prevent fluid retention or induce fluid loss; used in hypertension, congestive heart failure, renal disease, and liver disease.
High-kcalorie, high-protein diet	Contains foods that are kcalorie and protein dense.	Used for increased kcalorie and protein requirements (in cancer, AIDS, burns, trauma, and other illnesses); also used to reverse malnutrition, improve nutrition status, or promote weight gain.

SOURCES: American Dietetic Association, *Nutrition Care Manual* (Chicago: American Dietetic Association, 2005); American Dietetic Association, *Manual of Clinical Dietetics* (Chicago: American Dietetic Association, 2000).

Mechanically Altered Diets Mechanically altered diets are helpful for individuals who have difficulty chewing or swallowing. Chewing difficulties usually result from dental problems. Impaired swallowing, or **dysphagia**, may result from neurological disorders, surgical procedures involving the head and neck, and various physiological or anatomical abnormalities that restrict the movement of food within the throat or esophagus. Dysphagia diets are highly individualized because swallowing problems can vary greatly. Furthermore, patients must be monitored regularly because swallowing ability can fluctuate over time. Chapter 23 provides details about the specific diets used for treating dysphagia.

Table 18-5 lists examples of foods often included in mechanically altered diets. Some diets may contain mostly pureed foods (*pureed diet*), whereas a less restrictive diet may include moist, soft-textured foods that easily form a bolus (*mechanical soft diet,* or simply, *soft diet*). Diets for people with chewing problems typically include foods that are ground or minced (*ground/minced diet*). Note that the foods used in these diets can overlap, and individual tolerances should ultimately determine whether foods are included or excluded.

Blenderized Liquid Diet Blenderized diets may be prescribed following oral or facial surgeries (for example, jaw wiring) or be recommended to individuals with chewing problems. Soft or tender foods that can be blenderized (often with added liquid) are available from all food groups, and they include cereals and breads; cooked vegetables; fresh or cooked fruits without skins and seeds; cooked, tender meats and fish; and potatoes, rice, and pasta. Foods that do not blend well should be excluded; exam-

dysphagia: difficulty swallowing.

TABLE 18-5 Foods Included in Mechanically Altered Diets

Depending on the feeding problem, a mechanically altered diet may include foods that are pureed, mashed, ground, minced, or soft textured. Foods vary according to tolerance.

Pureed Diets	Mechanical Soft Diets
Milk products: Milk, smooth yogurt, pudding	**Milk products:** Milk, yogurt with soft fruit, pudding, cottage cheese
Fruits: Pureed fruits and juices without pulp, skin, seeds, or chunks; well-mashed fresh bananas; applesauce	**Fruits:** Canned or cooked fruits without seeds or skin, fruit juices with small amounts of pulp, ripe bananas
Vegetables: Pureed cooked vegetables without seeds or skins, mashed potatoes, pureed potatoes with gravy	**Vegetables:** Soft, well-cooked vegetables that are not rubbery or fibrous; well-cooked, moist potatoes
Meats and meat substitutes: Pureed meats (with gravy), pureed casseroles (with broth), hummus or other pureed legume spread	**Meats and meat substitutes:** Ground, minced, or tender meat, poultry, or fish with gravy or sauce; tofu; well-cooked legumes; scrambled eggs
Breads and cereals: Smooth cooked cereals such as cream of wheat, slurried breads and pancakes,[a] pureed rice and pasta	**Breads and cereals:** Cooked cereals or moistened dry cereals with minimal texture, soft pancakes or breads, well-cooked noodles or dumplings in sauce or gravy

[a] Slurried foods are mixed with liquid until the consistency is appropriate; they may be gelled and shaped to improve their appearance.
SOURCE: American Dietetic Association, *Nutrition Care Manual* (Chicago: American Dietetic Association, 2005).

ples include nuts and seeds, dried fruits, sausage and frankfurters, hard cheeses, raw vegetables, corn, and celery.

Clear Liquid Diet Clear liquids, which require minimal digestion and are easily tolerated by the gastrointestinal (GI) tract, are often the foods recommended before some GI procedures (such as GI examinations, X-rays, or surgeries), after GI surgery, or after fasting or intravenous feeding. The **clear liquid diet** consists of clear fluids and foods that are liquid at body temperature and leave little undigested material (called *residue*) in the colon. Permitted foods include clear or pulp-free fruit juices, carbonated beverages, clear meat and vegetable broths (such as consommé and bouillon), fruit-flavored or unflavored gelatin, fruit ices made from clear juices, frozen juice bars, and plain hard candy. Although the clear liquid diet provides fluid and electrolytes, its nutrient and energy contents are extremely limited. If used for longer than a day or two, this diet should be supplemented with commercially prepared low-residue formulas that provide required nutrients. Figure 18-2 on p. 624 gives an example of a one-day clear liquid menu.

Sometimes a **full liquid diet,** a liquid diet that is not limited to clear liquids, is used as a transitional diet between liquids and solid foods. In addition to clear liquids, a full liquid diet may include milk, eggnog, cream soups, and thin cereal gruels. Because the diet contains milk products, it may be inappropriate for patients with significant lactose intolerance. Moreover, a gradual progression from clear liquids to solid foods is generally unnecessary, ◆ so the usefulness of this diet is in question.

◆ A change in diet as a patient's food tolerance improves is called *diet progression.*

Fat-Restricted Diet A fat-restricted diet is recommended for reducing the symptoms of fat malabsorption, which frequently accompanies diseases of the liver, gallbladder, pancreas, and intestines. Fat restriction may also alleviate the symptoms of heartburn. Although fat intake is occasionally limited to as little as 25 grams daily, it should not be restricted more than necessary, because fat is an important source of kcalories. Chapter 24 provides additional information about fat-restricted diets.

Most foods included in a fat-restricted diet provide less than 1 gram of fat per serving. The diet includes fat-free milk products, most breads and cooked grains, fat-free broths and soups, vegetables prepared without fats, most fruits, and fat-free candies and sweets (see Table 24-5 on p. 762). Restricted foods include low-fat and whole-milk products, baked products with added fat (like muffins), and most

clear liquid diet: a diet that consists of foods that are liquid at body temperature, require minimal digestion, and contribute limited residue (undigested material) in the colon.

full liquid diet: a liquid diet that includes clear liquids, milk, yogurt, ice cream, and liquid nutritional supplements (such as Ensure).

FIGURE 18-2 Menu—Clear Liquid Diet

SAMPLE MENU

Breakfast	Strained orange juice
	Flavored gelatin
	Ginger ale
	Coffee or tea, sugar
Lunch	Bouillon or consommé
	Flavored gelatin
	Frozen juice bars
	Apple or grape juice
	Coffee or tea, sugar
Supper	Bouillon or consommé
	Flavored gelatin
	Fruit ice
	Cranberry juice
	Coffee or tea, sugar
Snacks	Soft drinks
	Fruit ices
	Hard candy

◆ Specific information about the fiber content of foods can be found in Chapter 4 (pp. 122–125) and Appendix H.

◆ The average sodium intake in the United States is approximately 3400 mg per day. The sodium UL was set at 2300 mg to help prevent hypertension.

prepared desserts. Lean meat and meat substitutes are permitted but may be restricted to 4 to 6 ounces per day, depending on the degree of restriction. Some patients with malabsorptive conditions cannot tolerate large amounts of lactose or dietary fiber, so foods that include these substances may also need to be excluded from the diet.

Fiber-Restricted Diet Fiber restriction is recommended during acute phases of intestinal disorders, when the presence of fiber may exacerbate intestinal discomfort or cause diarrhea or blockages. Fiber-restricted diets are sometimes used before surgery to minimize fecal volume and after surgery during transition to a regular diet. Long-term fiber restriction is discouraged, however, because it is associated with constipation, diverticulosis, and other problems.

Fiber-restricted diets often eliminate whole-grain breads and cereals, nuts and seeds, raw and dried fruits, berries, dried beans and peas, chunky peanut butter, winter squash, and most raw vegetables. ◆ If required, even greater reductions in colonic residue can be achieved by following a **low-residue diet**, which excludes most fruits and vegetables, foods high in resistant starch (see p. 107), milk products that contain significant lactose, and foods that contain fructose or sugar alcohols (such as sorbitol). These foods contribute to colonic residue because some of their nutrients may be poorly digested (such as the lactose in milk) or poorly absorbed (such as sorbitol and fructose). Note that the terms "low-fiber diet" and "low-residue diet" are often used interchangeably.

Sodium-Restricted Diet Sodium restriction can help to prevent or correct fluid retention and is often recommended for treatment of hypertension, congestive heart failure, kidney disease, and liver disease. The degree of restriction depends on the illness, the severity of symptoms, and the specific drug treatment prescribed. In most cases, sodium is restricted to 2000 or 3000 milligrams daily, although more severe restrictions may be used in the hospital setting. Many patients find it difficult to comply with sodium restrictions, so while the sodium recommendation is an attempt to improve the patient's medical problem, it may still exceed the tolerable upper intake level (UL) for sodium of 2300 milligrams. ◆

A sodium-restricted diet limits the use of salt (both in cooking and at the table), eliminates most prepared foods and condiments, and limits consumption of milk and milk products (if excessive). Because so many processed foods are high in sodium, people following a sodium-restricted diet should check food labels and consume only low-sodium products. Sodium restriction is difficult to implement on a long-term basis because many people find low-sodium diets unpalatable and fail to adhere to them. Additional information about sodium restriction is provided in Chapters 27 and 28.

High-kCalorie, High-Protein Diet The high-kcalorie, high-protein diet is used to increase kcalorie and protein intakes in patients who have unusually high requirements or in those who are eating poorly. High-fat foods are added to increase energy intakes; consequently, the diet may exceed 35 percent kcalories from fat. Consuming small, frequent meals and commercial liquid supplements (such as Ensure or Boost) can also help a patient meet increased energy, protein, and nutrient needs.

Examples of foods included in high-kcalorie, high-protein diets are listed in Table 18-6. Some of these foods are high in saturated fat, which is limited in heart-healthy diets. These foods are used liberally in diets for malnourished patients to help correct their immediate nutrition problems—weight loss and muscle wasting. Chapter 29 offers additional suggestions for increasing the kcalorie and protein contents of meals.

Alternative Feeding Routes

In most cases, patients meet their nutrient needs by consuming regular foods. If their nutrient needs are high or their appetites poor, liquid supplements can be added to their diets to improve their intakes. Sometimes, however, a person's med-

low-residue diet: a diet low in fiber and other food constituents that contribute to colonic residue.

TABLE 18-6 Foods Included in High-kCalorie, High-Protein Diets

Milk products	Whole milk, half-and-half, cream Cheese Milk shakes, eggnog Ice cream, whipped cream
Fruits	Dried fruit Canned fruit in heavy syrup Avocado
Vegetables	Vegetables prepared with butter, margarine, sour cream, mayonnaise, or salad dressing Cream of vegetable soups
Meats and high-protein foods	All meats, fish, and poultry, including bacon, frankfurters, and luncheon meats; eggs All meats, prepared fried or covered in cream sauces and gravies Nuts and seeds, peanut and other nut butters, coconut
Breads and cereals	Granola and dry cereals prepared with whole milk or cream and dried fruit Hot cereals with whole milk or cream, or added fat Pasta, rice, and potatoes with added fat Pancakes, waffles, French toast

ical condition makes it difficult to meet nutrient needs orally. Two options remain: **tube feedings** and **intravenous feedings,** described more fully in Chapters 20 and 21.

- *Tube feedings*. Nutritionally complete formulas can be delivered through a tube placed directly into the stomach or intestine. Tube feedings are preferred to intravenous feedings if the GI tract is functioning. For example, a person in a coma is unable to eat but may be able to digest foods and absorb nutrients normally. In this situation, a tube feeding would be the appropriate option.
- *Intravenous feedings*. A person's medical condition sometimes prohibits the use of the GI tract to deliver nutrients. If the person is malnourished and the GI tract cannot be used for a significant period of time, intravenous feedings (also called *parenteral nutrition*) can meet nutritional needs.

Nothing by Mouth (NPO)

An order to not give a patient anything at all—food, beverages, or medications—is indicated by NPO, an abbreviation for *non per os,* meaning "nothing by mouth." For example, an order may read "NPO for 24 hours" or "NPO until after X-ray." The NPO order is commonly used during certain acute illnesses or diagnostic tests involving the GI tract.

IN SUMMARY

Diets prescribed during illness can be modified in consistency, nutrient content, or food content. Mechanically altered diets are used for people with swallowing and chewing difficulties. Clear liquid diets may be used briefly after acute gastrointestinal disturbances or intravenous feedings or before various diagnostic tests. Some medical conditions may require the restriction of specific nutrients, such as fat, fiber, or sodium. A high-kcalorie, high-protein diet may help to prevent or reverse malnutrition, improve nutrition status, or promote weight gain. In some cases, nutrients need to be delivered via tube feedings or intravenously.

tube feedings: liquid formulas delivered through a tube placed in the stomach or intestine.

intravenous feedings: the provision of nutrients through a vein, bypassing the intestine; also called **parenteral nutrition.**

BananaStock/Jupiter Images

Foodservice departments strive to prepare appetizing and nutritious meals and may accommodate dozens of special diets.

Foodservice

The work of a foodservice department can appear deceptively simple: appropriate foods are delivered to patients who need specific types of diets. Behind the scenes, however, a complex system is at work. A foodservice department faces a daily challenge in planning, producing, and delivering hundreds of nutritious meals and accommodating dozens of special diets and food preferences.

Although this discussion focuses on the foodservice in hospitals, much of the information applies to the foodservice in any health care facility, including nursing homes, assisted living centers, rehabilitation centers, and residential mental health care facilities. An important difference between hospitals and long-term health care facilities deserves mention, however. When patients in hospitals eat poorly, they can make up for nutrient deficits by eating well when they return home. Residents of a long-term care facility do not have that option. For this reason, foodservice departments in long-term care facilities must make even greater efforts to ensure that their patients receive and consume nutritious foods.

Menu Planning

When designing menus for modified diets, the dietary and foodservice personnel refer to a **diet manual**, which details the exact foods or preparation methods to include or exclude in a modified diet. The diet manual may also outline the rationale and indications for use of the diets and include sample menus. The manual may be compiled by the dietetics staff or adopted from another health care facility or a dietetics organization.

Food Selection

Most hospitals provide **selective menus** from which patients can select their meals. A patient who must follow a modified diet receives menus that include only the foods specified in the hospital's diet manual for that particular diet. By allowing a choice, however, this system ensures that patients will receive the foods they prefer and are most likely to eat. An added advantage is that patients can become familiar with the modified diets as they select foods from the appropriate menus. Examples of selective menus are shown in Figure 18-3.

In hospitals that provide selective menus, patients may need to make menu selections a day or two in advance so that the foodservice department can estimate the amounts and types of food they need to purchase and prepare. Each menu identifies the patient and room number, the meal (breakfast, lunch, or supper), type of diet, and the day the food will be served. Menus are usually color-coded by diet, which helps to ensure that foodservice employees put the right foods on food trays. Color-coding also helps the person delivering the tray confirm that the right diet was delivered.

Sometimes a menu is not marked correctly or is misplaced, in which case the patient may receive a meal selected by the foodservice department. Other potential problems that may arise when selective menus are used include the following:

- Patients may have difficulty seeing, reading, understanding, or physically marking menus.
- Patients may not understand that their selections will be for the next (or another) day.

diet manual: a resource that specifies the foods allowed and restricted in modified diets and provides sample menus.

selective menus: menus that provide choices in some or all menu categories.

Name _____ Room _____

- Patients may be out of their rooms (for tests, procedures, or physical activity) or asleep when the menus arrive and may miss the menu pickup time.
- Patients may be too ill or too disinterested in food to make menu selections.

Problems with menu procedures can often be corrected by explaining the system or by taking the time to help patients mark menus.

Some hospitals do not offer selective menus. Instead, they may provide **nonselective menus** (menus with preselected food items) or menus that include some elements of both systems **(semiselective menus).** Nonselective menus have been gaining popularity in hospital foodservice because they simplify operations and may help to cut costs.

Food Preparation and Delivery

The responsibility for budgeting, purchasing, planning, preparing, and serving appropriate meals rests with either an administrative dietitian or a foodservice director. In some facilities, foodservice companies from outside the hospital are contracted to perform these duties.

The logistics of preparing foods tailored to each modified diet can be overwhelming. For this reason, foodservice departments use systems designed to limit costs and minimize errors. Meals may be produced in a central kitchen and delivered directly to patients' rooms, using serving equipment that keeps hot foods hot and cold foods cold. Another popular practice is to produce meals beforehand,

nonselective menus: menus that do not allow choices and list only preselected food items.

semiselective menus: menus that combine aspects of both selective and nonselective menus.

deliver trays to the nursing unit, and then reheat hot food items in areas close to the patients' rooms. Generally, foodservice personnel deliver food carts directly to the nursing unit, and then either nursing or foodservice personnel take trays to patients.

If a patient receives the wrong type of meal or receives foods that differ substantially from those requested, the dietetics or nursing staff should contact the foodservice department. A person's experience with foodservice strongly influences perception of the overall hospital stay;[10] thus, good communication between patients and the hospital staff regarding meals and food quality can substantially improve a patient's satisfaction.

Food Safety

Each institution has protocols for handling food products based on the identification of potential hazards and critical control points in food preparation, usually referred to as **HACCP (Hazard Analysis and Critical Control Points).**[11] Generally, an HACCP program addresses food handling, cooking, and storage procedures; cleaning and disinfecting of utensils, surfaces, and equipment; and staff sanitation issues. Personnel involved with preparing or delivering meals need to be aware of the specific HACCP systems at their facility.

Improving Food Intake

People in hospitals and other medical facilities often lose their appetites as a result of their medical condition, treatment, or emotional distress. Furthermore, some medications and other treatments can dramatically alter taste perceptions. Patients usually receive meals at specified times whether they are hungry or not and often must eat in bed without companionship; under these conditions, eating can be more of a chore than a pleasurable experience. Meals may also be unwelcome if the person is in pain or has been sedated.

Nurses, dietitians, and dietetic technicians often have central roles in helping patients to eat. Whenever possible, the patient's room should remain calm and quiet during mealtime. Excessive activity, like room maintenance or ward rounds, can distract patients and reduce appetite. If the patient's appetite or sense of taste is affected by illness, the health practitioner should work with the patient to identify foods that are the most enjoyable. When meals are served, the nurse can help the patient wash up before eating and check to see that foods and utensils are arranged attractively. Placing an occasional "surprise" on the tray—a decoration or funny card, for example—may help patients look forward to meals or perk up sagging spirits. The "How to" on p. 629 lists additional suggestions that may help to improve food intake at mealtimes.

IN SUMMARY

Hospital foodservice departments may accommodate the special needs of hundreds of patients daily. Diet manuals specify the foods to include in modified diets. Many hospitals provide selective menus from which patients can choose meals that are appropriate for their medical conditions. Hospital patients may need assistance at mealtime and encouragement to consume adequate amounts of food. The Case Study on p. 629 provides an opportunity for you to review the implementation of nutrition care.

HACCP (Hazard Analysis and Critical Control Points): systems of food or formula preparation that identify food safety hazards and critical control points during foodservice procedures.

HOW TO Help Hospital Patients Improve Their Food Intakes

1. Empathize with the patient. Show that you understand how difficult eating may be. Imagine feeling too sick to move or too tired to sit up.
2. Motivate. Be sure the patient understands how important nutrition is to recovery.
3. Help patients select the foods they like and mark menus appropriately. When appropriate and permissible, let friends or family members bring favorite foods from outside the hospital.
4. For patients who are weak, suggest foods that require little effort to eat. Eating a roast beef sandwich, for example, requires less effort than cutting and eating a steak. Drinking soup from a cup may be easier than eating it with a spoon.
5. Help patients prepare for meals. Help them get comfortable, either in bed or in a chair. Adjust the extension table to a comfortable distance and height, and make sure it is clean. Take these steps before the tray arrives, so the meal can be served promptly and at the right temperature.
6. When the food cart arrives, check the patient's tray. Confirm that the patient is receiving the right diet, that the foods on the tray are those selected from the menu, and that the foods look appealing. Order a new tray if foods are not appropriate.
7. Help with eating, if necessary. Help patients to open containers or cut foods, and help with feeding if patients cannot feed themselves.
8. Try to solve eating problems. Encourage patients with little appetite to eat the most nutritious foods first and to drink liquids between meals.
9. Take a positive attitude toward the hospital's food. Never say something like "I couldn't eat this either." Instead, say, "The foodservice department really tries to make foods appetizing. I'm sure we can find a solution."

CASE STUDY Implementing Nutrition Care

Max is an 11-year-old boy who was admitted to the hospital after he passed out while playing with friends. Tests confirm a diagnosis of type 1 diabetes mellitus. Max remains in the hospital for several days until his blood glucose and ketone levels are under control. During this time, he and his family learn about diabetes; the diet Max needs to follow; the use of insulin; the monitoring of blood glucose levels; and the required coordination of diet, insulin, and physical activity. The details of diabetes mellitus are reserved for Chapter 26, but for now you can consider the steps that are necessary for implementing Max's nutrition care.

1. Given the chronic nature of Max's illness and his age, what approaches should be used when discussing the required dietary and medical treatments with Max and his family? What factors need consideration when designing a nutrition education program for Max and his parents?
2. After a first visit with Max and his family, what information should the dietitian add to Max's medical record? Is enough information given above for designing a SOAP note? If not, what elements are missing?
3. Max will need additional care to learn more about diabetes and to make the adjustments that will allow him to cope with his condition. Why is it important to address follow-up care before Max leaves the hospital?

Clinical Portfolio

- David is a 49-year-old male who is 6 feet 2 inches tall and has a usual body weight of 180 pounds. He was admitted to the hospital following an automobile accident and was treated for minor injuries. Using the method described in the "How to" on p. 621, estimate his energy requirement using the appropriate WHO/FAO/UNU equation and the stress factor 1.25.
- A nutrition screening of an elderly woman admitted to the hospital for minor surgery revealed that she was not at risk for poor nutrition status. She was given a standard diet and was not referred to a dietitian for nutrition assessment. Following surgery, the woman developed several complications, and recovery was slower than expected. You notice that she has eaten only minimal amounts of food for several days and seems uninterested in meals. Describe several steps that can be taken to uncover and address problems that the woman might be having with food.

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login**.

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Give examples of the different types of nutrition interventions conducted in the clinical setting. Describe the various elements of the planning and implementation phases of a nutrition intervention. (pp. 615–616)
2. Compare the elements of the ADIME and SOAP formats that are often used for documenting nutrition care. Describe the components of a PES statement. (pp. 616–617)
3. Discuss the factors that should be considered when a patient is encouraged to make long-term dietary changes. Describe how a typical nutrition education session might be conducted. (pp. 617–619)
4. Explain how energy requirements are determined in the clinical setting. Compare the use of indirect calorimetry and predictive equations for determining RMR. (pp. 619–621)
5. Give examples of foods that are included in pureed diets, mechanical soft diets, and blenderized diets. Give examples of patients who may benefit from these diets. (pp. 621–623)
6. Describe the uses of the clear liquid diet, and list permitted foods. (p. 623)
7. Discuss the uses of the fat-restricted, fiber-restricted, and sodium-restricted diets. Give examples of the foods included in high-kcalorie, high-protein diets. (pp. 623–624)
8. Discuss the advantages and potential problems associated with the use of selective menus in hospital foodservice. (pp. 626–627)
9. Describe how health care professionals can help hospital patients improve their food intakes. (pp. 628–629)

These multiple choice questions will help you prepare for an exam. Answers can be found below.

1. Which style of nutrition documentation most closely reflects the steps of the nutrition care process?
   a. ADIME format
   b. SOAP format
   c. PES statement
   d. both a and b
2. A successful nutrition intervention would include a long list of:
   a. dietary changes that the patient should consider making.
   b. foods that the patient should avoid.
   c. appetizing meals and foods that the patient can include in the diet.
   d. reasons why the patient should make dietary changes.
3. The most important factor(s) that affect(s) how nutrition education is presented is (are):
   a. the person's nutrient needs and nutrition status.
   b. the person's abilities and motivation.
   c. the person's medical history.
   d. the entries in the medical record.
4. The Mifflin-St. Jeor equation:
   a. is considered the "gold standard" for determining RMR.
   b. predicts RMR using weight and height alone.
   c. predicts RMR for children, but not for adults.
   d. accurately predicts RMR in overweight and obese individuals.
5. Mechanically altered diets are often prescribed for individuals with:
   a. disorders of the liver, gallbladder, and pancreas.
   b. unusually high kcalorie and protein requirements.
   c. chewing and swallowing difficulties.
   d. malabsorptive disorders.
6. Foods permitted on the clear liquid diet include all of the following *except:*
   a. milk.
   b. fruit ices.
   c. flavored gelatin.
   d. consommé.
7. The modified diet *least* likely to provide adequate nutrients and kcalories is the:
   a. blenderized diet.
   b. clear liquid diet.
   c. ground/minced diet.
   d. high-kcalorie, high-protein diet.
8. Fiber restriction may be recommended:
   a. for patients with dysphagia.
   b. for patients who are unable to absorb fat normally.
   c. for patients with heartburn.
   d. during the acute phases of some intestinal disorders.
9. A hospital patient may occasionally be dissatisfied with selective menu procedures because:
   a. the system does not include food choices for individuals on modified diets.
   b. selective menus are difficult to understand and mark correctly.
   c. the opportunity to mark menus may be missed if patients are unavailable or asleep.
   d. foodservice operations cannot handle the food preferences of hundreds of patients.
10. A nurse notices a food on a patient's tray and is not sure if the food is allowed on the patient's diet. An appropriate action for the nurse to take would be to check the:
    a. nutrition care plan.
    b. diet manual.
    c. nutrition prescription.
    d. medical record.

Foodborne Illnesses

© Digital Imagery/PhotoDisc/Getty Images

Preparing meals to meet the special dietary needs of patients during times of sickness requires careful attention to food safety. An estimated 76 million people experience **foodborne illness** each year in the United States.[1] For some 5000 people each year, the adverse effects of the illness can be so severe as to cause death. Most vulnerable are pregnant women; very young, very old, sick, or malnourished people; and individuals with a weakened immune system (as in people with AIDS). By taking the proper precautions, people can minimize their chances of contracting foodborne illnesses.

Foodborne Infections and Food Intoxications

Foodborne illness can be caused by either infection or intoxication. Table H18-1 summarizes the most common or severe foodborne illnesses, along with their food sources, general symptoms, and prevention methods.

Foodborne Infections

Foodborne infections are caused by eating foods contaminated by microbes that can cause disease. The most common foodborne **pathogen** is *Salmonella,* which enters the GI tract in contaminated foods such as undercooked poultry and unpasteurized milk. Symptoms generally include abdominal cramps, fever, vomiting, and diarrhea.

Food Intoxications

Food intoxications are caused by eating foods containing natural toxins or, more likely, microbes that produce toxins. The most common food toxin is produced by *Staphylococcus aureus;* it affects more than one million people each year. Less common, but more infamous, is *Clostridium botulinum,* an organism that produces a deadly toxin in anaerobic conditions such as improperly canned (especially home-canned) foods and homemade garlic or herb-flavored oils stored at room temperature. Because the toxin paralyzes muscles, a person with botulism—*C. botulinum* intoxication—has difficulty seeing, speaking, swallowing, and breathing.[2] Because death can occur within 24 hours of onset, botulism demands immediate medical attention. Even then, survivors may suffer the effects for months or years.

Food Safety in the Marketplace

Transmission of foodborne illness has changed along with our food supplies and lifestyles.[3] In the past, foodborne illness was caused by one person's error in a small setting, such as improperly refrigerated egg salad at a family picnic, and it affected only a few victims. Today, we eat more foods that have been prepared and packaged by others for mass consumption. Consequently, when a food manufacturer or restaurant chef makes an error, foodborne illness can become epidemic. An estimated 80 percent of reported foodborne illnesses are caused by errors in a commercial setting, such as the improper **pasteurization** of milk at a large dairy.

GLOSSARY

cross-contamination: the contamination of food by bacteria that occurs when the food comes into contact with surfaces previously touched by raw meat, poultry, or seafood.

foodborne illness: illness transmitted to human beings through food and water, caused by either an infectious agent (foodborne infection) or a poisonous substance (food intoxication); commonly known as **food poisoning.**

pasteurization: heat processing of food that inactivates some, but not all, microorganisms in the food; not a sterilization process. Bacteria that cause spoilage are still present.

pathogen (PATH-oh-jen): a microorganism capable of producing disease.

sushi: vinegar-flavored rice and seafood, typically wrapped in seaweed and stuffed with colorful vegetables. Some sushi is stuffed with raw fish; other varieties contain cooked seafood.

TABLE H18-1 Foodborne Illnesses

Disease and Organism That Causes It	Most Frequent Food Sources	Onset and General Symptoms	Prevention Methods[a]
Foodborne Infections			
Campylobacteriosis (KAM-pee-loh-BAK-ter-ee-OH-sis) *Campylobacter* bacterium	Raw and undercooked poultry, unpasturized milk, contaminated water	Onset: 2 to 5 days. Diarrhea, vomiting, abdominal cramps, fever; sometimes bloody stools; lasts 2 to 10 days.	Cook foods thoroughly; use pasteurized milk; use sanitary food-handling methods.
Cryptosporidiosis (KRIP-toe-spo-rid-ee-OH-sis) *Crytosporidium parvum* parasite	Commonly contaminated swimming or drinking water, even from treated sources; highly chlorine-resistant; contaminated raw produce and unpasteurized juices and ciders	Onset: 2 to 10 days. Diarrhea, stomach cramps, upset stomach, slight fever; symptoms may come and go for weeks or months.	Wash all raw vegetables and fruits before peeling; use pasteurized milk and juice; do not swallow drops of water while using pools, hot tubs, ponds, lakes, rivers, or streams for recreation.
Cyclosporiasis (sigh-clo-spore-EYE-uh-sis) *Cyclospora cayetanensis* parasite	Contaminated water, contaminated fresh produce	Onset: 1 to 14 days. Watery diarrhea, loss of appetite, weight loss, stomach cramps, nausea, vomiting, fatigue; symptoms may come and go for weeks or months.	Use treated, boiled, or bottled water; cook foods thoroughly; peel fruits.
***E. coli* infection** *Escherichia coli*[b] bacterium	Undercooked ground beef, unpasteurized milk and juices, raw fruits and vegetables, contaminated water, person-to-person contact	Onset: 1 to 8 days. Severe bloody diarrhea, abdominal cramps, vomiting; lasts 5 to 10 days.	Cook ground beef thoroughly; use pasteurized milk; use sanitary food-handling methods; use treated, boiled, or bottled water.
Gastroenteritis[c] Norwalk virus	Person-to-person contact; raw foods, salads, sandwiches	Onset: 1 to 2 days. Vomiting; lasts 1 to 2 days.	Use sanitary food-handling methods.
Giardiasis (JYE-are-DYE-ah-sis) *Giardia intestinalis* parasite	Contaminated water; uncooked foods	Onset: 7 to 14 days. Diarrhea (but occasionally constipation), abdominal pain, gas.	Use sanitary food-handling methods; avoid raw fruits and vegetables where parasites are endemic; dispose of sewage properly.
Hepatitis (HEP-ah-TIE-tis) Hepatitis A virus	Undercooked or raw shellfish	Onset: 15 to 50 days (28 days average). Diarrhea, dark urine, fever, headache, nausea, abdominal pain, jaundice (yellowed skin and eyes from buildup of wastes); lasts 2 to 12 weeks.	Cook foods thoroughly.
Listeriosis (lis-TER-ee-OH-sis) *Listeria monocytogenes* bacterium	Unpasteurized milk; fresh soft cheeses; luncheon meats, hot dogs	Onset: 1 to 21 days. Fever, muscle aches; nausea, vomiting, blood poisoning, complications in pregnancy, and meningitis (stiff neck, severe headache, and fever).	Use sanitary food-handling methods; cook foods thoroughly; use pasteurized milk.
Perfringens (per-FRINGE-enz) **food poisoning** *Clostridium perfringens* bacterium	Meats and meat products stored at between 120°F and 130°F	Onset: 8 to 16 hr. Abdominal pain, diarrhea, nausea; lasts 1 to 2 days.	Use sanitary food-handling methods; cook foods thoroughly; refrigerate foods promptly and properly.
Salmonellosis (sal-moh-neh-LOH-sis) *Salmonella* bacteria (>2300 types)	Raw or undercooked eggs, meats, poultry, raw milk and other dairy products, shrimp, frog legs, yeast, coconut, pasta, and chocolate	Onset: 1 to 3 days. Fever, vomiting, abdominal cramps, diarrhea; lasts 4 to 7 days; can be fatal.	Use sanitary food-handling methods; use pasteurized milk; cook foods thoroughly; refrigerate foods promptly and properly.
Shigellosis (shi-gel-LOH-sis) *Shigella* bacteria (>30 types)	Person-to-person contact, raw foods, salads, sandwiches, contaminated water	Onset: 1 to 2 days. Bloody diarrhea, cramps, fever; lasts 4 to 7 days.	Use sanitary food-handling methods; cook foods thoroughly; use proper refrigeration.
Vibrio (VIB-ree-oh) **infection** *Vibrio vulnificus*[d] bacterium	Raw or undercooked seafood, contaminated water	Onset: 1 to 7 days. Diarrhea, abdominal cramps, nausea, vomiting; lasts 2 to 5 days; can be fatal.	Use sanitary food-handling methods; cook foods thoroughly.
Yersiniosis (yer-SIN-ee-OH-sis) *Yersinia enterocolitica* bacterium	Raw and undercooked pork, unpasteurized milk	Onset: 1 to 2 days. Diarrhea, vomiting, fever, abdominal pain; lasts 1 to 3 weeks.	Cook foods throughly; use pasteurized milk; use treated, boiled, or bottled water.
Food Intoxications			
Botulism (BOT-chew-lizm) Botulinum toxin [produced by *Clostridium botulinum* bacterium, which grows without oxygen, in low-acid foods, and at temperatures between 40°F and 120°F; the **botulinum** (BOT-chew-line-um) **toxin** responsible for botulism is called **botulin** (BOT-chew-lin)]	Anaerobic environment of low acidity (canned corn, peppers, green beans, soups, beets, asparagus, mushrooms, ripe olives, spinach, tuna, chicken, chicken liver, liver pâté, luncheon meats, ham, sausage, stuffed eggplant, lobster, and smoked and salted fish)	Onset: 4 to 36 hr. Nervous system symptoms, including double vision, inability to swallow, speech difficulty, and progressive paralysis of the respiratory system; often fatal; leaves prolonged symptoms in survivors.	Use proper canning methods for low-acid foods; refrigerate homemade garlic and herb oils; avoid commercially prepared foods with leaky seals or with bent, bulging, or broken cans.
Staphylococcal (STAF-il-oh-KOK-al) **food poisoning** Staphylococcal toxin (produced by *Staphylococcus aureus* bacterium)	Toxin produced in improperly refrigerated meats; egg, tuna, potato, and macaroni salads; cream-filled pastries	Onset: 1 to 6 hr. Diarrhea, nausea, vomiting, abdominal cramps, fever; lasts 1 to 2 days.	Use sanitary food-handling methods; cook food thoroughly; refrigerate foods promptly and properly; use proper home-canning methods.

NOTE: Travelers' diarrhea is most commonly caused by *E. coli, Campylobacter jejuni, Shigella,* and *Salmonella.*

[a]The "How to" on pp. 636–637 provides more details on the proper handling, cooking, and refrigeration of foods.

[b]The most serious strain is *E. coli* STEC O157.

[c]Gastroenteritis refers to an inflammation of the stomach and intestines but is the most common name used for illnesses caused by Norwalk viruses.

[d]Most cases of *Vibrio vulnificus* infection occur in persons with underlying illness, particularly those with liver disorders, diabetes, cancer, and AIDS, and those who require long-term steroid use. The fatality rate is 50 percent for this population.

© Polara Studios, Inc.

To prevent food intoxication from homemade flavored oils, wash and dry the herbs before adding them to the oil and keep the oil refrigerated.

In the mid-1990s, when a fast-food restaurant served undercooked burgers tainted with an infectious strain of *Escherichia coli,* hundreds of patrons became ill, and at least 3 people died. In the early 2000s, a national food company had to recall more than 4 million pounds of poultry products after *Listeria* poisoning killed 7 people and made more than 50 others sick. In the 2006 *E. coli* outbreak due to contaminated fresh spinach, nearly 200 people became sick, and 2 elderly women and a 2-year-old boy died before consumers got the FDA message not to eat fresh spinach. These incidents and others have focused the national spotlight on two important safety issues: disease-causing organisms are commonly found in raw foods, and thorough cooking kills most of these foodborne pathogens. This heightened awareness sparked a much needed overhaul of national food safety programs.

Industry Controls

To make our food supply safe for consumers, the USDA, the FDA, and the food-processing industries have developed and implemented programs to control foodborne illness.* The Hazard Analysis Critical Control Points (HACCP) system requires food manufacturers to identify points of contamination and implement controls to prevent foodborne disease. For example, after tracing two large outbreaks of salmonellosis to imported cantaloupe, producers began using chlorinated water to wash the melons and to make ice for packing and shipping. Safety procedures such as this prevent hundreds of thousands of foodborne illnesses each year and are responsible for the decline in infections over the past decade.[4]

This example raises another issue regarding the safety of imported foods. FDA inspectors cannot keep pace with the increasing numbers of imported foods; they inspect fewer than 2 percent of the almost 3 million shipments of fruits, vegetables, and seafood coming into more than 300 ports in the United States each year. The FDA is working with other countries to adopt the safe food-handling practices used in the United States.

Consumer Awareness

Canned and packaged foods sold in grocery stores are easily controlled, but rare accidents do happen. Batch numbering makes it possible to recall contaminated foods through public announcements via newspapers, television, and radio. In the grocery store, consumers can buy items before the "sell by" date and inspect the safety seals and wrappers of packages. A broken seal, bulging can lid, or mangled package alerts consumers to the possibility of microbe or insect contamination, spoilage, or even vandalism.

State and local health regulations provide guidelines on the cleanliness of facilities and the safe preparation of foods for restaurants, cafeterias, and fast-food establishments. Even so, consumers can also take these actions to help prevent foodborne illnesses when dining out:

- Wash hands with hot, soapy water before meals.
- Expect clean tabletops, dinnerware, utensils, and food preparation areas.
- Expect cooked foods to be served piping hot and salads to be fresh and cold.
- Refrigerate doggy bags within two hours.

Improper handling of foods can occur anywhere along the line, from commercial manufacturers to large supermarkets to small restaurants to private homes. Maintaining a safe food supply requires everyone's efforts (see Figure H18-1).

Food Safety in the Kitchen

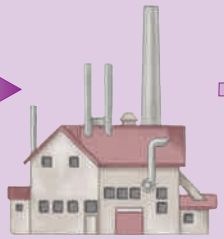
Whether microbes multiply and cause illness depends, in part, on a few key food-handling behaviors in the kitchen—whether the kitchen is one in your home, a hospital cafeteria, a gourmet restaurant, or a canning manufacturer.[5] Figure H18-2 summarizes the four simple things that can help most to prevent foodborne illness:

- *Keep a clean, safe kitchen.* Wash countertops, cutting boards, hands, sponges, and utensils in hot, soapy water before and after each step of food preparation.
- *Avoid cross-contamination.* Keep raw eggs, meat, poultry, and seafood separate from other foods. Wash all utensils and surfaces (such as cutting boards or platters) that have been in contact with these foods with hot, soapy water before using them again. Bacteria inevitably left on the surfaces from the raw meat can recontaminate the cooked meat or other foods—a problem known as **cross-contamination.** Washing raw eggs, meat, and poultry is not recommended because the extra handling increases the risk of cross-contamination.
- *Keep hot foods hot.* Cook foods long enough to reach internal temperatures that will kill microbes, and maintain ade-

* In addition to the HACCP, these programs include the Emerging Infections Program (EIP), the Foodborne Diseases Active Surveillance Network (FoodNet), and the Food Safety Inspection Service (FSIS).

FIGURE H18-1 Food Safety from Farms to Consumers

FARMS
Workers must use safe methods of growing, harvesting, sorting, packing, and storing food to minimize contamination hazards.



PROCESSING
Processors must follow FDA guidelines concerning contamination, cleanliness, and education and training of workers and must monitor for safety at critical control points (use HACCP, see text).

TRANSPORTATION
Containers and vehicles transporting food must be clean. Cold food must be kept cold at all times.

RETAIL GROCERY STORES AND RESTAURANTS
Employees must follow the FDA's food code on how to prevent foodborne illnesses. Establishments must pass local health inspections and train staff in sanitation.

CONSUMERS
Consumers must learn and use sound principles of food safety as taught in this chapter. Be mindful that foodborne illness is a real possibility, and take steps to prevent it.

FIGURE H18-2 Fight Bac!

Four ways to keep food safe. The Fight Bac! website is at **www.fightbac.org.**

quate temperatures to prevent bacterial growth until the foods are served.

- *Keep cold foods cold.* Go directly home upon leaving the grocery store, and place foods in the refrigerator or freezer right away. After a meal, refrigerate any leftovers immediately.

Unfortunately, consumers commonly fail to follow these simple food-handling recommendations.[6] See the "How to" on pp. 636–637 for additional food safety tips.

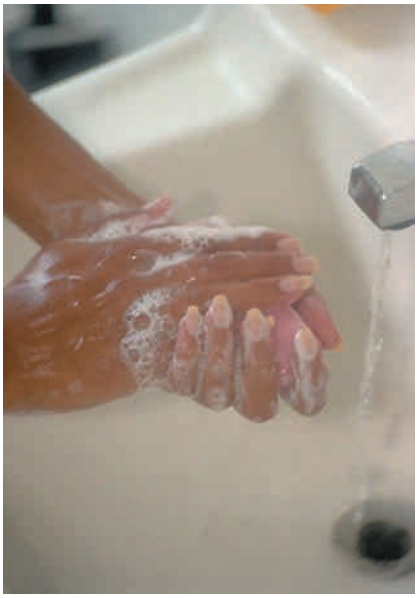
Safe Handling of Meats and Poultry

Meats and poultry contain bacteria and provide a moist, nutrient-rich environment that favors microbial growth. Ground meat is especially susceptible because it receives more handling than other kinds of meat and has more surface exposed to bacterial

Dietary Guidelines for Americans 2005

To avoid microbial foodborne illness:

- Clean hands, food contact surfaces, and fruits and vegetables.
- Separate raw, cooked, and ready-to-eat foods while shopping, preparing, or storing foods.
- Do *not* wash or rinse meat and poultry.
- Cook foods to a safe temperature to kill microorganisms.
- Chill (refrigerate) perishable food promptly, and defrost foods properly.



© PhotoDisc/Getty Images

Wash your hands with warm water and soap for at least 20 seconds before preparing or eating food to reduce the chance of microbial contamination.

HOW TO Prevent Foodborne Illness

Most foodborne illnesses can be prevented by following four simple rules: keep a clean kitchen, avoid cross-contamination, keep hot foods hot, and keep cold foods cold.

Keep a Clean Kitchen

- Wash fruits and vegetables in a clean sink with a scrub brush and warm water; store washed and unwashed produce separately.
- Use hot, soapy water to wash hands, utensils, dishes, nonporous cutting boards, and countertops before handling food and between tasks when working with different foods. Use a bleach solution on cutting boards (one capful per gallon of water).
- Cover cuts with clean bandages before food preparation; dirty bandages carry harmful microorganisms.
- Mix foods with utensils, not hands; keep hands and utensils away from mouth, nose, and hair.
- Anyone may be a carrier of bacteria and should avoid coughing or sneezing over food. A person with a skin infection or infectious disease should not prepare food.
- Wash or replace sponges and towels regularly.
- Clean up food spills and crumb-filled crevices.

Avoid Cross-Contamination

- Wash all surfaces that have been in contact with raw meats, poultry, eggs, fish, and shellfish before reusing.
- Serve cooked foods on a clean plate. Separate raw foods from those that have been cooked.
- Don't use marinade that was in contact with raw meat for basting or sauces.

Keep Hot Foods Hot

- When cooking meats or poultry, use a thermometer to test the internal temperature. Insert the thermometer between the thigh and the body of a turkey or into the thickest part of other meats, making sure the tip of the thermometer is not in contact with bone or the pan. Cook to the temperature indicated for that particular meat (see Figure H18-4 on p. 637); cook hamburgers to at least medium well-done. If you have safety questions, call the USDA Meat and Poultry Hotline: (800) 535-4555.
- Cook stuffing separately, or stuff poultry just prior to cooking.
- Do not cook large cuts of meat or turkey in a microwave oven; it leaves some parts undercooked while overcooking others.
- Cook eggs before eating them (soft-boiled for at least 3½ minutes; scrambled until set, not runny; fried for at least 3 minutes on one side and 1 minute on the other).
- Cook seafood thoroughly. If you have safety questions about seafood, call the FDA hotline: (800) FDA-4010.
- When serving foods, maintain temperatures at 140°F or higher.
- Heat leftovers thoroughly to at least 165°F.

Keep Cold Foods Cold

- When running errands, stop at the grocery store last. When you get home, refrigerate the perishable groceries (such as meats and dairy products) immediately. Do not leave perishables in the car any longer than it takes for ice cream to melt.
- Put packages of raw meat, fish, or poultry on a plate before refrigerating to prevent juices from dripping on food stored below.
- Buy only foods that are solidly frozen in store freezers.
- Keep cold foods at 40°F or less; keep frozen foods at 0°F or less (keep a thermometer in the refrigerator).
- Marinate meats in the refrigerator, not on the counter.

contamination. Consumers cannot detect the harmful bacteria in or on meat. Figure H18-3 presents label instructions for the safe handling of meat and poultry and two types of USDA seals. For safety's sake, cook meat thoroughly, using a thermometer to test the internal temperature (see Figure H18-4).

Mad Cow Disease

Reports on mad cow disease from dozens of countries, including Canada and the United States, have sparked consumer concerns.[7] Mad cow disease is a slowly progressive, fatal condition that affects the central nervous system of cattle.* A similar disease develops in people who have eaten contaminated beef from infected cows (milk products appear to be safe).† Approximately 150 cases have been reported worldwide, primarily in the United Kingdom. The USDA has taken numerous steps to prevent the transmission of mad cow

* Mad cow disease is technically known as bovine spongiform encephalopathy (BSE).
† The human form of BSE is called variant Creutzfeldt-Jakob disease (vCJD).

FIGURE H18-3 Meat and Poultry Safety, Grading, and Inspection Seals

Inspection is mandatory; grading is voluntary. Neither guarantees that the product will not cause foodborne illnesses, but consumers can help to prevent foodborne illnesses by following the safe handling instructions.

HOW TO Prevent Foodborne Illness, *continued*

- Refrigerate leftovers promptly; use shallow containers to cool foods faster; use leftovers within 3 to 4 days.
- Thaw meats or poultry in the refrigerator, not at room temperature. If you must hasten thawing, use cool water (changed every 30 minutes) or a microwave oven.
- Freeze meat, fish, or poultry immediately if not planning to use within a few days.

In General

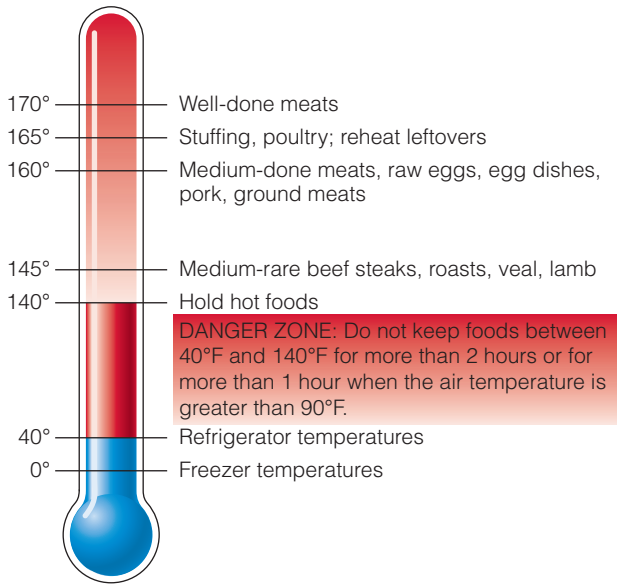
- Do not reuse disposable containers; use nondisposable containers or recycle instead.
- Do not taste food that is suspect. "If in doubt, throw it out."
- Throw out foods with danger-signaling odors. Be aware, though, that most food-poisoning bacteria are odorless, colorless, and tasteless.
- Do not buy or use items that have broken seals or mangled packaging; such containers cannot protect against microbes, insects, spoilage, or even vandalism. Check safety seals, buttons, and expiration dates.
- Follow label instructions for storing and preparing packaged and frozen foods; throw out foods that have been thawed or refrozen.
- Discard foods that are discolored, moldy, or decayed or that have been contaminated by insects or rodents.

For Specific Food Items

- *Canned goods.* Carefully discard food from cans that leak or bulge so that other people and animals will not accidentally ingest it; before canning, seek professional advice from the USDA Extension Service (check your phone book under U.S. government listings, or ask directory assistance).
- *Milk and cheeses.* Use only pasteurized milk and milk products. Aged cheeses, such as cheddar and Swiss, do well for an hour or two without refrigeration, but they should be refrigerated or stored in an ice chest for longer periods.
- *Eggs.* Use clean eggs with intact shells. Do not eat eggs, even pasteurized eggs, raw; raw eggs are commonly found in Caesar salad dressing, eggnog, cookie dough, hollandaise sauce, and key lime pie. Cook eggs until whites are firmly set and yolks begin to thicken.
- *Honey.* Honey may contain dormant bacterial spores, which can awaken in the human body to produce botulism. In adults, this poses little hazard, but infants under one year of age should never be fed honey. Honey can accumulate enough toxin to kill an infant; it has been implicated in several cases of sudden infant death. (Honey can also be contaminated with environmental pollutants picked up by the bees.)
- *Mayonnaise.* Commercial mayonnaise may actually help a food to resist spoilage because of the acid content. Still, keep it cold after opening.
- *Mixed salads.* Mixed salads of chopped ingredients spoil easily because they have extensive surface area for bacteria to invade, and they have been in contact with cutting boards, hands, and kitchen utensils that easily transmit bacteria to food (regardless of their mayonnaise content). Chill them well before, during, and after serving.
- *Picnic foods.* Choose foods that last without refrigeration, such as fresh fruits and vegetables, breads and crackers, and canned spreads and cheeses that can be opened and used immediately. Pack foods cold, layer ice between foods, and keep foods out of water.
- *Seafood.* Buy only fresh seafood that has been properly refrigerated or iced. Cooked seafood should be stored separately from raw seafood to avoid cross-contamination.

FIGURE H18-4 Recommended Safe Temperatures (Fahrenheit)

Bacteria multiply rapidly at temperatures between 40°F and 140°F. Cook foods to the temperatures shown on this thermometer and hold them at 140°F or higher.



disease in cattle, and if these measures are followed, then risks from eating meat from U.S. cattle are low.[8] Because the infectious agents occur in the intestines, central nervous system, and other organs, but not in muscle meat, concerned consumers may want to select whole cuts of meat instead of ground beef or sausage. A few recent reports of hunters developing fatal neurological disorders have raised concerns about a similar disease in wild game. Hunters and consumers who regularly eat elk, deer, or antelope should check the advisories of their state department of agriculture.

Avian Influenza

Avian influenza (bird flu) is a very contagious and life-threatening viral infection that naturally occurs among birds, including chickens, ducks, and turkeys. The risk of bird flu in human beings is relatively low, and most cases have resulted from direct contact with infected birds or their contaminated environment. Because the virus can change easily,

© Eric O'Connell/Getty Images

Cook hamburgers to 160°F; color alone cannot determine doneness. Some burgers will turn brown before reaching 160°F, whereas others may retain some pink color, even when cooked to 175°F.

Eating raw seafood is a risky proposition.

scientists are concerned that it could infect people and spread rapidly from person to person, creating a pandemic. It is important to note that bird flu is not transmitted by eating poultry.

Safe Handling of Seafood

Most seafood available in the United States and Canada is safe, but eating it undercooked or raw can cause severe illnesses—hepatitis, worm or parasite infestation, viral intestinal disorders, and other diseases.* Rumor has it that freezing fish will make it safe to eat raw, but this is only partly true. Commercial freezing kills mature parasitic worms, but only cooking can kill all worm eggs and other microorganisms that can cause illness. For safety's sake, all seafood should be cooked until it is opaque. Even **sushi** can be safe to eat when chefs combine cooked seafood and other ingredients into these delicacies.

Eating raw oysters can be dangerous for anyone, but people with liver disease and weakened immune systems are most vulnerable. At least 10 species of bacteria found in raw oysters can cause serious illness and even death.† Raw oysters may also carry the hepatitis A virus, which can cause liver disease. Some hot sauces can kill many of these bacteria, but not the virus; alcohol may also protect some people against some oyster-borne illnesses, but not enough to guarantee protection (or to recommend drinking alcohol). Pasteurization of raw oysters—holding them at a specified temperature for a specified time—holds promise for killing bacteria without cooking the oysters or altering their texture or flavor.

As population density increases along the shores of seafood-harvesting waters, pollution inevitably invades the sea life there. Preventing seafood-borne illness is in large part a task of controlling water pollution. To help ensure a safe seafood market, the FDA requires processors to adopt food safety practices based on the HACCP system mentioned earlier.

Chemical pollution and microbial contamination lurk not only in the water but also in the boats and warehouses where seafood is cleaned, prepared, and refrigerated. Because seafood is one of the most perishable foods, time and temperature are critical to its freshness, flavor, and safety. To keep seafood as fresh as possible, people in the industry must "keep it cold, keep it clean, and keep it moving." Wise consumers eat it cooked.

Other Precautions and Procedures

Fresh food generally smells fresh. Not all types of food poisoning are detectable by odor, but some bacterial wastes produce "off" odors. If an abnormal odor exists, the food is spoiled. Throw it out or, if it was recently purchased, return it to the grocery store. Do not taste it. Table H18-2 lists safe refrigerator storage times for selected foods.

Local health departments and the USDA Extension Service can provide additional information about food safety. If precautions fail and a mild foodborne illness develops, drink clear liquids to replace fluids lost through vomiting and diarrhea. If serious foodborne illness is suspected, first call a physician. Then wrap the remainder of the suspected food and label the container so that the food cannot be mistakenly eaten, place it in the refrigerator, and hold it for possible inspection by health authorities.

Dietary Guidelines for Americans 2005

- To avoid microbial foodborne illness, avoid raw (unpasteurized) milk or any products made from unpasteurized milk, raw or partially cooked eggs or foods containing raw eggs, raw or undercooked meat and poultry, unpasteurized juices, and raw sprouts.

* Diseases caused by toxins from the sea include ciguatera, scombroid poisoning, and paralytic and neurotoxic shellfish poisoning.
† Raw oysters can carry the bacterium *Vibrio vulnificus;* see Table H18-1 for details.

TABLE H18-2 Safe Refrigerator Storage Times (≤40°F)

1 to 2 Days	Raw ground meats, breakfast or other raw sausages, raw fish or poultry; gravies
3 to 5 Days	Raw steaks, roasts, or chops; cooked meats, poultry, vegetables, and mixed dishes; lunch meats (packages opened); mayonnaise salads (chicken, egg, pasta, tuna)
1 Week	Hard-cooked eggs, bacon or hot dogs (opened packages); smoked sausages or seafood
2 to 4 Weeks	Raw eggs (in shells); lunch meats, bacon, or hot dogs (packages unopened); dry sausages (pepperoni, hard salami); most aged and processed cheeses (Swiss, brick)
2 Months	Mayonnaise (opened jar); most dry cheese (Parmesan, Romano)

Millions of people suffer mild to life-threatening symptoms caused by foodborne illnesses (review Table H18-1). As the "How to" on pp. 636–637 describes, most of these illnesses can be prevented by storing and cooking foods at their proper temperatures and by preparing them in sanitary conditions.

Nutrition in the Clinical Setting

When health care practitioners prescribe medications, follow-up is essential. Health practitioners should confirm that patients are taking prescription drugs as directed and that they fully understand the prescription directions. Patients may feel uncomfortable admitting their uncertainty about the directions, intolerance to side effects, or inability to purchase the drugs they need. Others may feel hesitant to discuss their use of herbal products. Patients are more likely to confide in health care providers who take the time to discuss these difficulties.

CHAPTER 19

Medications, Herbal Products, and Diet-Drug Interactions

CHAPTER OUTLINE

Medications in Disease Treatment • Risks from Medications • Patients at High Risk of Adverse Effects

Herbal Products • Effectiveness and Safety of Herbal Products • Use of Herbal Products in Illness

Diet-Drug Interactions • Drug Effects on Food Intake • Drug Effects on Nutrient Absorption • Dietary Effects on Drug Absorption • Drug Effects on Nutrient Metabolism • Dietary Effects on Drug Metabolism • Drug Effects on Nutrient Excretion • Dietary Effects on Drug Excretion • Diet-Drug Interactions and Toxicity

HIGHLIGHT 19 Anemia in Illness

People frequently rely on medications to prevent and treat health problems. They may also use herbal products, which have become a popular alternative therapy. Because any ingested chemical can affect metabolism and potentially disrupt body processes, both medications and herbal products may produce adverse effects. Serious side effects may occur when medications interact with each other (drug-drug interactions) or with nutrients and other dietary components (diet-drug interactions). This chapter discusses the uses of medications and herbal supplements and describes potential diet-drug interactions.

Medications in Disease Treatment

Medications must be proved to be safe and effective before they can be marketed in the United States. The Food and Drug Administration (FDA) is responsible for approving sales of new drugs and inspecting facilities where drugs are manufactured. It also oversees the advertising of prescription drugs and labeling of over-the-counter drugs.[1]

Prescription Drugs Prescription drugs are usually given to treat serious conditions and may cause severe side effects. For these reasons, they are sold by prescription only, which ensures that a physician has evaluated the patient's medical condition and determined that the benefits of using the medication outweigh the risks of incurring side effects.

Over-the-Counter Drugs Over-the-counter (OTC) drugs are those that can be used safely and effectively without medical supervision. People usually use them to treat less serious illnesses that are easily self-diagnosed. Examples include aspirin to treat headaches or pain, decongestants to relieve stuffy noses, and antacids to combat indigestion. Prescription drugs considered safe enough for self-medication are frequently switched to OTC status, sometimes in smaller doses than are available by prescription. Labels on OTC drugs are regulated and provide information about the drugs' appropriate uses, dosages, and potential adverse effects.

© Bill Aron/PhotoEdit

Although over-the-counter drugs are considered safe enough for self-medication, they can cause adverse effects when used inappropriately.

Health care practitioners should caution patients that adverse effects may occur if OTC drugs are used inappropriately. Under certain circumstances, the active ingredients in these drugs can worsen medical conditions, produce complications, and interact with other medications. Furthermore, people using products with several active ingredients may inadvertently take toxic amounts of a substance when using several drugs simultaneously. For example, a person with a cold may take one medication to treat a cough and another medication for a headache without realizing that both contain an analgesic (pain medication).

Generic Drugs Brand-name drugs are usually given patent protection for 20 years after the patent is submitted. After the patent protection expires, generic versions of the drugs can be sold. To gain FDA approval, a generic drug must have the same biological effects as the original drug: it must contain the same active ingredients; be identical in strength, dosage form, and route of administration; and meet the same requirements for purity and quality. Thus, consumers can be confident that generic drugs are as safe and effective as the brand-name products they replace. ◆ The advantage is a substantial savings—generic drugs typically cost 20 to 75 percent less than their brand-name counterparts.

◆ Consumers can search for generic equivalents to brand-name drugs at **www.fda.gov/cder/ob/default.htm.**

Risks from Medications

The risk of an adverse reaction always accompanies the use of a medicine. Thus, a medication should be used only when the benefits of using it outweigh the potential risks. Before prescribing drug treatments, health professionals should discuss with patients the potential side effects of using the medications and should also advise them if alternative treatments are available. The risks associated with medications become greater when a drug is incorrectly prescribed or administered. This section discusses the types of risks associated with drugs and suggests some steps for managing risk.[2]

Side Effects By the time a drug reaches the marketplace, large-scale clinical trials have revealed the majority of side effects associated with its use. However, rare side effects are sometimes detected only after a drug has been more widely used. In some instances, these effects occur because drugs are used for longer periods or in different circumstances than originally anticipated. The FDA monitors adverse events after drugs are marketed. Manufacturers are required to submit periodic reports, and individuals using the drugs are encouraged to report unexpected effects directly to the FDA. ◆ In some cases, the FDA may decide to change labeling information or even withdraw drugs from the marketplace due to their unacceptable risks to health.

◆ The FDA's MedWatch program encourages health professionals and consumers to report medication problems by mail, fax, telephone, or the Internet (**www.fda.gov/medwatch**).

Drug-Drug Interactions When a person uses multiple drugs, one drug may alter the effects of another drug, and the risk of side effects increases. These problems are common in older adults, who are likely to use several medications daily over long periods. Primary care physicians often supervise medication use, but some individuals use drugs prescribed by a number of different physicians. Others may use OTC medications and dietary supplements in addition to prescription drugs without being aware of the risks associated with certain combinations.

Diet-Drug Interactions Substances in the diet may alter the effectiveness of drugs, and drugs may affect food intake, digestion, absorption, metabolism, or excretion of nutrients. The second half of this chapter describes these interactions and explains how they may affect nutrition status.

Medication Errors A medication error is any preventable action that causes inappropriate drug use or patient harm due to mistakes made by a health professional or patient. Many errors leading to patient harm involve the use of incorrect drugs or improper dosages.[3] The wrong drug is sometimes administered when two different drugs have names that look or sound alike or have similar packaging. In other cases, the physician's prescription is misread or misinterpreted; for example, a patient died after receiving 10 milliliters of morphine solution instead of 10 milligrams—a 20-fold overdose.

Several policy changes and programs are helping to reduce medication errors. For example, the bar codes currently used on medications and patient identification bracelets allow health practitioners to verify that the correct medication and dosage is administered: error messages alert personnel if the drug, dose, or timing of administration is inappropriate. In addition, a national education campaign is attempting to eliminate one of the most common but preventable sources of medication errors—the use of ambiguous medical abbreviations (see the examples in Table 19-1). Because terms such as these are easily misread or misinterpreted, they can no longer be used in clinical documentation related to patient care.

Patients at High Risk of Adverse Effects

Health care professionals should be aware that some patients are more vulnerable than others to adverse effects from drugs. This category includes the populations that rarely participate in clinical trials that determine product safety: pregnant and lactating women, children, and people with medical conditions that are not the main focus of the study. In these groups, side effects may be discovered only after a drug has been marketed. Children may react in different ways to drugs than adults do, and the appropriate dosage for their age and size is often unknown. Also, limited data are available on drug safety in older adults. Elderly people with chronic

TABLE 19-1 Terms Prohibited on Clinical Documentation

Prohibited Terms	Intended Meaning	Potential Problem	Correct Term for Documentation
U	Unit	Can be misread as the number 0 or 4; may cause 10-fold overdose or higher.	Write out "unit."
IU	International unit	Can be misread as IV (intravenous) or 10.	Write out "international unit."
Trailing zero (1.0 mg) or lack of leading zero (.1 mg)	1 mg; 0.1 mg	Decimal point can be missed, leading to 10-fold error in dosages.	Never use zero by itself after a decimal. Always use zero before a decimal point.
HS, hs	*HS* means "half-strength"; *hs* means "bedtime" (abbreviation for "hours of sleep").	Can be mistaken for one another.	Write out "half-strength" or "bedtime."
µg	Microgram	Can be misread as mg (milligram).	Write "mcg."
A.S., A.D., A.U.	Abbreviations of the Latin for left ear, right ear, and both ears	Can be misread as O.S., O.D., and O.U., meaning left eye, right eye, and both eyes.	Write out full words.
T.I.W.	Three times a week	Can be mistaken for "three times a day" or "twice weekly."	Write out "3 times weekly."
Q.D. (q.d.), Q.O.D (q.o.d.)	*Q.D.* means "every day"; *Q.O.D.* means "every other day."	Can be mistaken for one another or misread as "q.i.d." (four times daily).	Write out "daily" or "every other day."
q1d	Daily	Can be misread as q.i.d. (four times daily).	Write out "daily."

Elderly people using multiple medications are especially susceptible to adverse effects from drugs.

◆ Reminder: Highlight 10 discusses vitamin and mineral supplements.

diseases that require multiple medications are especially susceptible to adverse effects. They are also more likely to have impaired function of the liver or kidneys—the two organs critical to metabolizing and eliminating drugs from the body. The "How to" below provides suggestions that may help to reduce the risks of adverse effects from medications.

IN SUMMARY

Both prescription and OTC drugs must be shown to be safe and effective before they are sold. The benefits of using a medication should be greater than the risks associated with its use. Potential risks include side effects, drug-drug and diet-drug interactions, and medication errors. The most common types of medication errors involve incorrect dosages or use of the wrong drug. Patients at highest risk of experiencing adverse effects from medications include pregnant and nursing women, children, and the elderly. Health professionals should discuss the risks and benefits of medications with patients and alert them to potential dangers and possible solutions.

Herbal Products

Use of herbal products has grown rapidly in the past decade. In a 2004 research study of 61,587 older adults (ages 50 to 76 years), researchers found that one-third of the participants used herbal and other specialty (nonplant) supplements.[4] ◆ Consumers use these products in the hope of improving their general health and preventing or treating specific diseases. The top-selling herbal supplements include ginseng, echinacea, *Ginkgo biloba,* garlic, and St. John's wort.[5] Table 19-2 lists these and other popular herbs along with their common uses and potential risks associated with their use.

Effectiveness and Safety of Herbal Products

Despite the popularity of herbal products in the United States, the benefits of their use are uncertain. The marketplace is currently inundated with herbal "remedies" of dubious effectiveness. There is no question that many medicinal herbs contain naturally occurring compounds that can exert physiological effects. Few herbal products, however, have been rigorously tested, many make unfounded claims, and some contain contaminants or produce toxic effects.[6]

HOW TO Reduce the Risks of Adverse Effects from Medications

To limit the risks of adverse effects from medications, health care providers can take the following steps:

- Advise the patient that drugs should not be taken unless absolutely necessary. Discuss dietary or lifestyle practices that may have benefits similar to those of drugs. For example, individuals may not need to take laxatives if they increase consumption of foods high in fiber and begin exercising regularly.
- Request a complete list of prescription medications, over-the-counter drugs, and dietary supplements that a patient is taking. Make sure that at least one physician is coordinating the patient's drug use.
- Verify that the patient understands how to take medications properly. Alert the patient to potential interactions between drugs and between drugs and dietary substances.
- Encourage the patient to keep track of adverse effects. Inform patients that new or unusual symptoms may be the result of a medication rather than their medical condition. In some cases, other medications that treat the same condition may have fewer side effects.
- Encourage the patient to purchase all medications at the same pharmacy so that the pharmacist can alert the physician and patient to potential problems.
- Include information about drug safety when providing health education.

TABLE 19-2 Popular Herbs, Their Common Uses, and Adverse Effects

Herb	Scientific Name	Common Uses	Adverse Effects
Black cohosh	*Cimicifuga racemosa*	Relief of menopausal symptoms	Rare; occasional stomach upset, headache, weight gain
Chaparral	*Larrea tridentata*	General tonic; treatment of infection, cancer, and arthritis	Hepatitis, liver failure
Comfrey	*Symphytum officinale*	Wound healing (topical use), treatment of lung and GI disorders	Liver damage
Echinacea	*Echinacea augustifolia, E. pallida, E. purpurea*	Prevention and treatment of upper respiratory infections	Rare; occasional allergic reactions
Feverfew	*Tanacetum parthenium*	Prevention of migraine headache	Mouth and tongue sores, swelling of lips, GI upset
Garlic	*Allium sativum*	Reduction of blood clotting, atherosclerosis, blood pressure, and blood cholesterol	Halitosis (bad breath), body odor; occasional dyspepsia, flatulence, excessive bleeding, anorexia, allergic reactions
Ginger	*Zingiber officinale*	Prevention and treatment of nausea and motion sickness	Rare; occasional heartburn
Ginkgo	*Ginkgo biloba*	Treatment of dementia, memory defects, and circulatory impairment	Rare; occasional stomach upset, headache, skin hypersensitivity, excessive bleeding
Ginseng	*Panax ginseng, P. quinquefolius*	General tonic, reduction of blood glucose levels	Rare
Kava	*Piper methysticum*	Treatment of anxiety, stress, and insomnia	Dyspepsia, restlessness, drowsiness, tremor, headache, dermatitis (with heavy use), occasional hepatitis and liver failure
St. John's wort	*Hypericum perforatum*	Treatment of mild to moderate depression	Rare; occasional stomach upset, fatigue, dizziness, headache, dry mouth, dermatitis, skin photosensitivity
Saw palmetto	*Serenoa repens*	Reduction of symptoms associated with enlarged prostate	Rare
Valerian	*Valeriana officinalis*	Sedation, treatment of insomnia	Rare
Yohimbe	*Pausinystalia yohimbe*	Treatment of erectile dysfunction	Anxiety, headache, dizziness, nausea, rapid heartbeat, hypertension, increased urinary frequency; isolated reports of renal failure, blood disorders, and airway constriction

SOURCE: M. Rotblatt and I. Ziment, *Evidence-Based Herbal Medicine* (Philadelphia: Hanley & Belfus, 2002).

Efficacy Herbs have been used for centuries to treat medical conditions, and many have acquired reputations for being beneficial for people with specific diseases. Unfortunately, only a limited number of clinical studies support the traditional uses, and the results of studies that suggest little or no benefit are rarely publicized by the supplement industry. The National Center for Complementary and Alternative Medicine (a division of the National Institutes of Health) is currently funding large, controlled trials of several popular herbal treatments in an effort to obtain reliable efficacy and safety data.

Although labels on herbal products cannot make claims about preventing or treating specific diseases, suggestive statements are common. For example, a label may claim that an herb "promotes restful sleep" but cannot state that it cures insomnia. Stores often shelve herbal products by health condition; for example, posted signs may indicate the supplements suggested for "liver health" or "men's health." The reading materials positioned close to those shelves often suggest that the products can improve one's health.

Consistency of Herbal Ingredients Herbs contain numerous compounds, and it is often unclear which of these ingredients, if any, might produce the implied beneficial effects. Because the compounds in herbs vary among species and are affected by a plant's growing conditions, different samples of an herb can have different chemical compositions. The preparation method may also cause variations in the composition of an herbal product. Some manufacturers attempt to standardize the herbal

© Sheila Terry/Photo Researchers, Inc.

Despite the popularity of echinacea, its benefits for treating the common cold have not been supported by some well-designed clinical studies.

extracts they sell so that the compound believed to be beneficial is more likely to be obtained from each dose.

Even when the active ingredients in an herbal supplement have been shown to be safe and effective, the dosage suggested on the label might not provide the quantity of active ingredients found to be effective. For example, a consumer group (ConsumerLab.com) tested nine *Ginkgo biloba* products and found that seven of the products, when consumed at the recommended dosage, lacked adequate levels of one or more compounds believed to be helpful.[7] In some cases, the desired herbal product is not even present. In a university study of echinacea preparations, 10 percent of the 59 products tested contained no measurable echinacea, and only 52 percent of the samples contained the variety of echinacea listed on the label.[8]

Safety Issues Unlike drugs, herbal products do not need FDA approval before they are marketed. According to the Dietary Supplement Health and Education Act (DSHEA) of 1994, the companies that produce or distribute dietary (including herbal) supplements are responsible for determining their safety, but these companies are not required to provide any evidence. If a company receives reports of illness or injury related to the use of its products, it does not need to submit this information to the FDA. In addition, the FDA must show that a supplement is unsafe before it can take action to remove the product from the marketplace.

Consumers of herbal supplements often assume that because plants are "natural," herbal products must be harmless. Many herbal remedies have toxic effects, however. The most common adverse effects of herbs include diarrhea, nausea, and vomiting.[9] The popular herbs kava, chaparral, and comfrey have caused liver damage. The use of yohimbe (promoted for bodybuilding) has been linked to renal failure, seizures, and heart palpitations. In 2004, the FDA removed the herb ephedra (also known as *ma huang*) from the market, advising that its side effects (which include elevated blood pressure and rapid heartbeat) could cause heart attack or stroke. ◆ Note that the adverse effects of herbs are seldom listed on supplement labels.

◆ Although the FDA ruling to ban ephedra was overturned by a Utah district court in 2005, the ruling was upheld by an appellate court in August 2006.

Like drugs, herbs may either intensify or interfere with the effects of other herbs and drugs. Information about herb-drug interactions is limited, however, and much of what is known has been obtained from case studies rather than from controlled clinical trials. An herb may increase or decrease the effects of medications, or it may raise the risk of toxicity. For example, garlic, ginkgo, and ginseng may increase the risk of bleeding when used with anticoagulant drugs.[10] St. John's wort has been found to inhibit the actions of oral contraceptives, anticoagulants, and other drugs. Individuals may be more susceptible to the adverse effects of a drug if the herb they are using has a similar effect; for example, ginger and ginseng contain compounds that raise blood pressure and may increase the toxicity of drugs that have a similar side effect.[11] Table 19-3 provides examples of herb-drug interactions.

Contamination of herbal products is another safety concern. Some products have been found to contain lead and other toxic metals in excessive amounts.[12] Other contaminants frequently found in herbal products include molds, bacteria, and pesticides that have been banned for use on food crops.[13] Adulteration of imported products has been a serious concern: several studies found that some herbal products imported from China and India contained synthetic drugs that were not declared on the label.[14] There have also been reports of serious illnesses and fatalities occurring from the intentional or accidental substitutions of one plant species for another.[15]

Use of Herbal Products in Illness

When people self-medicate or ask the advice of store clerks instead of seeking effective medical treatment, the consequences are sometimes serious and irreversible. A

TABLE 19-3 Examples of Herb-Drug Interactions

Herb	Drug	Interaction
American ginseng	Estrogens, corticosteroids	Enhances hormonal response
American ginseng	Breast cancer therapeutic agent	Synergistically inhibits cancer cell growth
American ginseng, karela	Blood glucose regulators	Affect blood glucose levels
Echinacea (possible immunostimulant)	Cyclosporine and corticosteroids (immunosuppressants)	May reduce drug effectiveness
Evening primrose oil, borage	Anticonvulsants	Lower seizure threshold
Feverfew	Aspirin, ibuprofen, and other nonsteroidal anti-inflammatory drugs	Negates the effect of the herb in treating migraine headaches
Feverfew, garlic, ginkgo, ginger, and Asian ginseng	Warfarin, coumarin (anticlotting drugs, "blood thinners")	Prolong bleeding time; increase likelihood of hemorrhage
Garlic	Protease inhibitor (HIV drug)	May reduce drug effectiveness
Kava, valerian	Anesthetics	May enhance drug action
Kelp (iodine source)	Synthroid or other thyroid hormone replacers	Interferes with drug action
Kyushin, licorice, plantain, uzara root, hawthorn, Asian ginseng	Digoxin (cardiac antiarrhythmic drug derived from the herb foxglove)	Interfere with drug action and monitoring
St. John's wort, saw palmetto, black tea	Iron	Tannins in herbs inhibit iron absorption
Valerian	Barbiturates	Causes excessive sedation

visit to the health-food store for an herbal remedy may be less stressful than a visit to the doctor, but it may delay getting an appropriate treatment and allow an illness to progress. Consumers should inform their health care providers about their use of herbal supplements so that a comprehensive care plan can be developed and potential problems can be averted.

Many people are unaware that herbal products can interact with medications. Because research on herbs is often lacking, assessing potential interactions is difficult for health care professionals and patients alike. Some pharmacology textbooks and handbooks now contain information about herbal products and potential herb-drug interactions, and various consumer websites and periodicals provide information about the safety of brand-name products. Health professionals should turn to these resources when a patient reports use of herbal products.

IN SUMMARY

Herbal products are not reliable treatments for medical conditions; there is little evidence demonstrating their effectiveness and safety, and the concentrations of active ingredients may vary greatly. Manufacturers and distributors of herbal supplements are responsible for determining product safety, and the FDA is unable to take action against unsafe supplements before they reach the market. Safety concerns include adverse effects, herb-drug interactions, and contamination. Consumers using herbs may delay getting an appropriate treatment for their condition.

Diet-Drug Interactions

When working with patients, medical personnel should be alert to possible interactions between drugs and dietary substances. These interactions can raise health care costs and result in serious, and sometimes fatal, complications. With hundreds of diet-drug interactions known and more to be identified in the future, health professionals must learn to take steps to prevent or lessen their adverse consequences. Diet-drug interactions generally fall into the following categories:

- Drugs can alter food intake by reducing the appetite or by causing complications that make food consumption difficult or unpleasant. Some drugs may increase appetite and cause weight gain.
- Drugs can alter the absorption, metabolism, and excretion of nutrients. Conversely, nutrients and other food components can alter the absorption, metabolism, and excretion of drugs.
- Some interactions between dietary components and drugs can be toxic.

Examples of these types of diet-drug interactions are shown in Table 19-4. The remaining sections of this chapter describe some specific diet-drug interactions and their clinical significance.[16]

Drug Effects on Food Intake

Some drugs can make food intake difficult or unpleasant: they may suppress the appetite, alter taste sensations, induce nausea or vomiting, cause mouth dryness, or lead to inflammation or lesions in the mouth or GI tract. Certain side effects, including abdominal discomfort, constipation, and diarrhea, may be worsened by food consumption. Medications that cause drowsiness, such as sedatives and some painkillers, can make a person too tired to eat.

Drug complications that reduce food intake are significant only when they continue for a long period. Although many drugs can cause nausea in some individuals, the nausea often subsides after the first few doses of the medication and thus has little effect on nutrition status. If side effects persist, other medications may be used to treat them; for example, antinauseants and antiemetics may help to reduce nausea and vomiting and thereby improve food intake.

Some medications stimulate food intake and encourage weight gain. Unintentional weight gain may result from the use of some antipsychotics, antidepressants, and corticosteroids (for example, prednisone). People using these drugs may be unable to feel satiated and may gain 40 to 60 pounds in just a few months. For some conditions, however, weight gain is desirable. Patients with diseases that cause wasting, such as cancer or AIDS, are sometimes prescribed appetite enhancers such as megestrol acetate, a progesterone analog, or dronabinol, which is derived from the active ingredient in marijuana.

Drug Effects on Nutrient Absorption

◆ *Antineoplastic drugs* combat tumor growth. *Antiretroviral drugs* treat HIV infection.

The medications that most often cause widespread nutrient malabsorption are those that damage the intestinal mucosa. Antineoplastic and antiretroviral drugs ◆ are especially detrimental, although nonsteroidal anti-inflammatory drugs (NSAIDs) and some antibiotics can have similar, though milder, effects. This section describes additional ways in which medications may alter nutrient absorption.

Drug-Nutrient Binding Some medications bind nutrients in the GI tract, preventing their absorption. For example, bile acid binders, which reduce cholesterol levels, may bind to fat-soluble vitamins. Some antibiotics, notably tetracycline and ciprofloxacin, bind to the calcium in foods and supplements, reducing the absorption

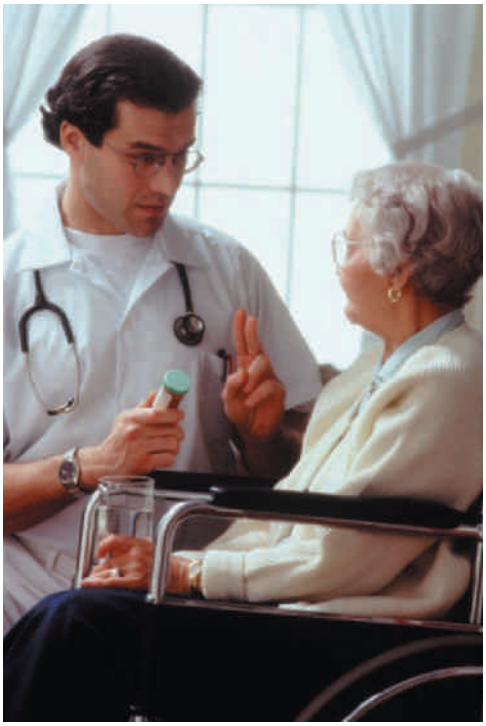
TABLE 19-4 Examples of Diet-Drug Interactions

Drugs May Alter Food Intake by:
Altering the appetite (amphetamines suppress appetite; corticosteroids increase appetite).
Interfering with taste or smell (amphetamines change taste perceptions).
Inducing nausea or vomiting (digitalis may do both).
Interfering with oral function (some antidepressants may cause dry mouth).
Causing sores or inflammation in the mouth (methotrexate may cause painful mouth ulcers).
Drugs May Alter Nutrient Absorption by:
Changing the acidity of the digestive tract (antacids may interfere with iron and folate absorption).
Damaging mucosal cells (cancer chemotherapy may damage mucosal cells).
Binding to nutrients (bile acid binders bind to fat-soluble vitamins).
Foods and Nutrients May Alter Drug Absorption by:
Stimulating secretion of gastric acid (the antifungal agent ketoconazole is absorbed better with meals due to increased acid secretion).
Altering rate of gastric emptying (intestinal absorption of drugs may be delayed when they are taken with food).
Binding to drugs (calcium binds to tetracycline, reducing drug and calcium absorption).
Competing for absorption sites in the intestine (dietary amino acids interfere with levodopa absorption).
Drugs and Nutrients May Interact and Alter Metabolism by:
Acting as structural analogs (as do warfarin and vitamin K).
Using similar enzyme systems (phenobarbital induces liver enzymes that increase metabolism of folate, vitamin D, and vitamin K).
Competing for transport on plasma proteins (fatty acids and drugs may compete for the same sites on the plasma protein albumin).
Drugs May Alter Nutrient Excretion by:
Altering reabsorption in the kidneys (some diuretics increase the excretion of sodium and potassium).
Causing diarrhea or vomiting (diarrhea and vomiting may cause electrolyte losses).
Food May Alter Medication Excretion by:
Inducing activities of liver enzymes that metabolize drugs to allow their excretion (components of charcoal-broiled meats increase metabolism of warfarin, theophylline, and acetaminophen).
Toxicity May Occur from Combining Foods and Drugs by:
Increasing side effects of the drug (caffeine in beverages can increase adverse effects of stimulants).
Increasing drug action to excessive levels (grapefruit components may block metabolism of drugs and enhance drugs' actions and side effects).

of both the calcium and the antibiotic. Other minerals, such as iron, magnesium, and zinc, can also bind to some antibiotics. Consumers are advised to use dairy products and all mineral supplements at least 2 hours apart from these medications.

Altered Stomach Acidity Medications that reduce stomach acidity can impair the absorption of vitamin B_{12}, folate, and iron. Examples include antacids, which neutralize stomach acid by acting as weak bases, and antiulcer drugs (such as proton pump inhibitors and H2 blockers), which interfere with acid secretion.

Direct Inhibition Several drugs impede nutrient absorption by interfering with their intestinal metabolism or transport into mucosal cells. For example, the antibiotics trimethoprim and pyrimethamine compete with folate for absorption into intestinal cells.



© Jose L. Pelaez/Corbis

To help prevent diet-drug interactions, ask about *all* of the drugs and supplements a patient takes, including prescription and over-the-counter drugs, herbal products, and other dietary supplements.

Dietary Effects on Drug Absorption

Most drugs are absorbed in the upper small intestine. Major influences on drug absorption include the stomach-emptying rate, the level of acidity in the stomach, and direct interactions with dietary components. The drug's formulation may also influence its absorption. The instructions included with medications typically advise whether food should be included or avoided with use.

Stomach-Emptying Rate Drugs reach the small intestine more quickly when the stomach is empty. Therefore, taking a medication with meals may delay its absorption, although the total amount absorbed may not be lower. As an example, aspirin works faster when taken on an empty stomach, although taking it with food is often encouraged to reduce stomach irritation.

Slow stomach emptying can enhance drug absorption, because the drug's absorption sites in the small intestine do not become saturated. Slow drug absorption due to slow stomach emptying can be a problem, however, if high drug concentrations are needed for effectiveness, as when a hypnotic is taken to induce sleep.

Stomach Acidity Some drugs are better absorbed in an acidic environment, so conditions that are too alkaline may reduce their absorption. Hence, antacid medications may reduce the absorption of these drugs. Other drugs can be damaged by acid and are often available in coated forms that resist the stomach's acidity.

Interactions with Dietary Components Some dietary substances can bind to drugs and inhibit their absorption. For example, the phytates in foods can bind to digoxin, a drug prescribed for heart disease. ◆ High-fiber diets may decrease the absorption of some tricyclic antidepressants. As mentioned earlier, calcium can bind to some antibiotics, reducing absorption of both the calcium and the drug.

◆ Reminder: *Phytates* are compounds found in many plant foods, including whole grains and legumes. Phytates can bind to minerals and other substances and reduce their absorption.

Drug Effects on Nutrient Metabolism

Drugs and nutrients share similar enzyme systems in the small intestine and liver. Consequently, some drugs may enhance or inhibit the activities of enzymes needed for nutrient metabolism. For example, the anticonvulsants phenobarbital and phenytoin increase levels of the liver enzymes that metabolize folate, vitamin D, and vitamin K; therefore, persons using these drugs may require supplements of these vitamins.

The drug methotrexate, used to treat cancer and inflammatory conditions, acts by interfering with folate metabolism and thus depriving rapidly dividing cancer cells of the folate they need to multiply. Methotrexate resembles folate in structure (see Figure 19-1) and competes with folate for the enzyme that converts folate to its active form. The adverse effects of using methotrexate therefore include symptoms of folate deficiency. These adverse effects can be reduced by using a preactivated form of folate (called leucovorin), which is often prescribed along with methotrexate to ensure that the body's rapidly dividing cells (such as cells of the digestive tract, skin cells, and red blood cells) receive adequate folate.

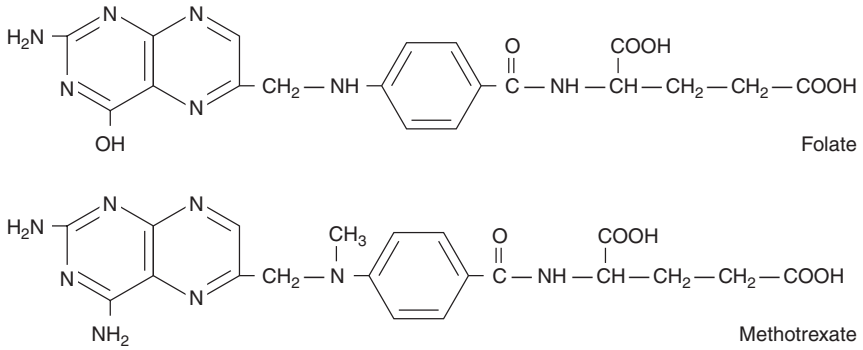
Isoniazid (INH), an antituberculosis drug, sometimes induces vitamin B_6 deficiency. Isoniazid is similar in structure to vitamin B_6 and can therefore interfere with the vitamin's conversion to its active form. Because the drug must be taken for at least six months to treat infection, vitamin B_6 supplements are often given to prevent deficiency.[17]

Corticosteroids, used as anti-inflammatory agents and immunosuppressants, have actions that mimic those of the hormone cortisol. ◆ Long-term corticosteroid use can have broad effects on nutritional health and may cause weight gain, muscle wasting, bone loss, and hyperglycemia, with eventual development of osteoporosis and diabetes.

◆ Cortisol is a steroid hormone secreted by the adrenal cortex as part of the body's stress response.

FIGURE 19-1 Folate and Methotrexate

By competing for the enzyme that activates folate, methotrexate prevents cancer cells from obtaining the folate they need to multiply. In the process, normal cells are also deprived of the folate they need.



Dietary Effects on Drug Metabolism

Some food components alter the activities of enzymes that metabolize drugs or may counteract drug effects in other ways. Compounds in grapefruit juice (and whole grapefruit) have been found to inhibit or inactivate enzymes that metabolize a number of different drugs. As a result of the reduced enzyme action, blood concentrations of the drugs increase, leading to stronger physiological effects. The effect of the grapefruit juice lasts for a substantial period after the juice is consumed; for example, in experiments with a drug prescribed for heart disease, the juice's effect had an estimated half-life of 12 hours.[18] ◆ Table 19-5 on p. 652 provides examples of drugs that interact with grapefruit juice, as well as some common drugs that are unaffected.

◆ Reminder: The term *half-life* can be used to define the time period of a chemical effect. If the grapefruit effect has a 12-hour half-life, this means that after 12 hours, its biological effect is half of the maximum effect measured.

A number of dietary substances can alter the activity of the anticoagulant drug warfarin. The most important interaction is with vitamin K, which is structurally similar to warfarin. Warfarin acts by blocking the enzyme that activates vitamin K, thereby preventing the synthesis of blood-clotting factors. ◆ The amount of warfarin prescribed is dependent, in part, on how much vitamin K is in the diet. If vitamin K consumption from foods or supplements increases substantially, it can weaken the effect of the drug. Individuals using warfarin are advised to consume similar amounts of vitamin K daily to keep warfarin activity stable. The dietary sources highest in vitamin K are green leafy vegetables.

◆ Reminder: Vitamin K is required for the synthesis of prothrombin and several other blood-clotting proteins.

Several popular herbs contain natural compounds that may enhance the activity of warfarin and therefore should be avoided during warfarin treatment. These herbs include St. John's wort, garlic, ginseng, dong quai, danshen, and others.[19]

Drug Effects on Nutrient Excretion

Drugs that enhance urinary excretion can interfere with nutrient reabsorption in the kidneys, ◆ resulting in greater urinary losses of the nutrients. For example, some diuretics can accelerate the excretion of calcium, potassium, magnesium, and thiamin, and dietary supplements may be necessary to avoid deficiency. Risk of nutrient depletion is highest if multiple drugs with the same effect are used, if kidney function is impaired, or if the medications are used for a long time. Note that some diuretics can cause certain minerals to be retained, rather than excreted.[20]

◆ When the kidneys reabsorb a substance, they retain it in the blood. Substances that are not reabsorbed are excreted in urine.

TABLE 19-5 Examples of Grapefruit Juice–Drug Interactions

Drug Category	Drugs Affected by Grapefruit Juice	Drugs Unaffected by Grapefruit Juice
Cardiovascular drugs	Felodipine	Amlodipine
	Nicardipine	Diltiazem
	Nifedipine	Propafenone
	Verapamil	Quinidine
Cholesterol-lowering drugs	Atorvastatin	Pravastatin
	Lovastatin	
	Simvastatin	
Central nervous system drugs	Buspirone	Clomipramine
	Carbamazepine	Haloperidol
	Diazepam	
	Triazolam	
Anti-infective drugs	Saquinavir	Clarithromycin
		Itraconazole
Estrogens	Ethinylestradiol	17-β-estradiol
Anticoagulants	—	Acenocoumarol
		Warfarin
Immunosuppressants	Cyclosporine	Prednisone
	Tacrolimus	
Antiasthmatic drugs	—	Theophylline

SOURCE: D. G. Bailey, M. O. Arnold, and J. D. Spence, Inhibitors in the diet: Grapefruit juice–drug interactions, in R. H. Levy and coeditors, *Metabolic Drug Interactions* (Phildelphia: Lippincott Williams & Wilkins, 2000), pp. 661–669.

Dietary Effects on Drug Excretion

◆ Lithium is used to prevent mood swings in patients with bipolar disorder.

Inadequate excretion of medications can cause toxicity, whereas excessive losses may reduce the amount available for therapeutic effect. Some food components can alter drug reabsorption by the kidneys. For example, the amount of the medication lithium ◆ reabsorbed by the kidneys is similar to the amount of sodium reabsorbed. Thus, both sodium depletion and dehydration, which increase sodium reabsorption, can result in lithium retention. Similarly, a person with a high sodium intake will excrete more sodium in the urine, and therefore more lithium. Individuals using lithium are advised to maintain a consistent sodium intake from day to day in order to maintain a stable blood level of lithium.[21]

Urine acidity can affect drug excretion due to the effects of pH on a compound's ionic (chemical) form. The medication quinidine, used to treat arrhythmias, is excreted more readily in acidic urine. Foods or drugs that cause urine to become more alkaline may reduce quinidine excretion and raise blood levels of the medication.

Diet-Drug Interactions and Toxicity

Interactions between food components and drugs can cause toxicity or exacerbate a drug's side effects. The combination of tyramine, a food component, and monoamine oxidase (MAO) inhibitors, which include some antidepressants and a medication that treats Parkinson's disease, can be fatal. MAO inhibitors block an enzyme that normally inactivates tyramine, as well as the hormones epinephrine

and norepinephrine. When people who take MAO inhibitors consume excessive tyramine, the increased tyramine in the blood can induce a sudden release of accumulated norepinephrine. This surge in norepinephrine results in severe headaches, rapid heartbeat, and a dangerous rise in blood pressure. For this reason, people taking MAO inhibitors are advised to restrict their intakes of foods rich in tyramine.

Tyramine occurs naturally in foods and is also formed when bacteria degrade the protein in foods. Thus, the tyramine content of a food usually increases when a food ages or spoils. Individuals at risk of tyramine toxicity are advised to buy mainly fresh foods and consume them promptly.[22] Foods that often contain substantial amounts of tyramine are listed in Table 19-6.

Considering the number of medications available and the many ways in which drugs and dietary substances can interact, it should not be surprising that serious side effects are increasingly recognized. Health professionals should attempt to understand the mechanisms of diet-drug interactions, identify them when they occur, and prevent them whenever possible. The "How to" below offers some practical advice about preventing diet-drug interactions.

TABLE 19-6 Examples of Foods with a High Tyramine Content[a]

- Aged cheeses
- Aged meats
- Alcoholic beverages (beer, wine)
- Anchovies
- Caviar
- Fava beans
- Fermented foods (sauerkraut, sausages)
- Feta cheese
- Lima beans
- Mushrooms
- Pickled fish or meat
- Prepared soy foods (miso, tempeh, tofu)
- Smoked fish or meat
- Soy sauce
- Yeast extract (Marmite)

[a]The tyramine content of foods depends on storage conditions and processing; thus the amounts in similar products can vary substantially.

IN SUMMARY

Medications can alter food intake and affect the absorption, metabolism, and excretion of nutrients. Components of foods can similarly affect the absorption, metabolism, and excretion of medications. Some drugs may reduce appetite and cause damage to the GI tract. Binding between drugs and nutrients may inhibit their absorption. Drugs and nutrients may interfere with each other's metabolism because they use similar enzymes in the small intestine and liver. Diet-drug interactions may cause excessive losses of nutrients and alter the urinary excretion of medications.

HOW TO Prevent Diet-Drug Interactions

The Joint Commission, an accreditation agency for health care organizations, has recommended that all patients be educated about potential diet-drug interactions. Health professionals can help by informing patients of precautions related to medications and watching for signs of problems that may arise.

To prevent diet-drug interactions, first list the types and amounts of over-the-counter drugs, prescription medications, and dietary supplements that the patient uses on a regular basis. Look up each medication in a drug reference and make a note of:

- The appropriate method of administration (twice daily or at bedtime, for example).
- How the medication should be administered with respect to foods, beverages, and specific nutrients (for example, take on an empty stomach, take with food, do not take with milk, or do not drink alcoholic beverages while using the medication).
- How the medication should be used with respect to other medications.
- The side effects that may affect food intake (nausea and vomiting, constipation or diarrhea, or sedation, for example) or nutrient needs (interference with nutrient absorption or metabolism, for example).

A similar process can be used to review the dietary supplements that a person is taking. A reliable reference may list their appropriate uses, possible side effects, and potential interactions with food and medications.

Patients who take multiple medications may need help learning when to take each medication to avoid drug-drug or diet-drug interactions. The health practitioner can use information from a patient's diet history (see Chapter 17) to help the patient coordinate meals and drugs so as to avoid interactions.

Some medications have well-known effects on nutrition status. The health practitioner should remain alert for signs of problems, especially when:

- Nutritional problems are a frequent result of using the medication.
- A patient uses multiple medications.
- The patient is in a high-risk group, for example, a child, a pregnant or lactating woman, an older adult, or a person who is malnourished, abuses alcohol, or has impaired liver or kidney function.
- The patient needs to use the medication for a long period of time.

Check with the pharmacist for additional information about medications and potential interactions.

Clinical Portfolio

- A patient mentions that he regularly takes six to seven dietary and herbal supplements and that he has not told the physician that he uses them. His prescription medications include an antihypertensive agent (to reduce blood pressure) and warfarin. What approach might you take to learn the details about the patient's supplement use and his reasons for taking them? If you discover that some of the supplements may pose a risk for diet-drug or herb-drug interactions with his prescription medications, what steps should you take?
- An elderly woman in a residential home has been losing weight since her arrival there. She has been taking several medications to treat both a heart problem and a mild case of bronchitis. You notice that she eats only a few bites at mealtimes and seems disinterested in food. Describe several steps you can take to learn whether the medications are interfering with her food intake in some way.

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Describe similarities and differences among prescription medications, over-the-counter drugs, and generic versions of drugs. (pp. 641–642)
2. Identify factors that frequently cause medication errors. What recommendations have been proposed to reduce the incidences of these errors? (pp. 642–643)
3. Explain why some patient populations are at high risk for adverse effects from drugs. (pp. 643–644)
4. Explain why herbal products are not dependable treatments for medical conditions. Describe possible dangers associated with the use of these products. (pp. 644–647)
5. Discuss ways in which medications can affect food intake. (pp. 648–649)
6. Describe how medications can interfere with nutrient absorption and how dietary factors can affect drug absorption. (pp. 648–650)
7. Explain how drugs and nutrients may influence each other's metabolism, and provide examples. (pp. 650–651)
8. Discuss diet-drug interactions that can alter the excretion of nutrients or medications. Explain why tyramine intake must be monitored by people using monoamine oxidase (MAO) inhibitors. (pp. 651–653)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 656.

1. Over-the-counter drugs are:
   a. unlikely to cause adverse effects.
   b. unlikely to interact with dietary components.
   c. generally used for longer periods of time than prescription medications.
   d. used to treat illnesses that are normally self-diagnosed and self-treated.

2. Recommendations for reducing incidences of medication errors include:
   a. physician supervision whenever drugs are administered.
   b. advising patients to take only one medication at a time.
   c. requiring that prescriptions be typed instead of handwritten.
   d. avoiding the use of confusing terms on clinical documents.
3. Adverse drug effects are most likely when:
   a. multiple medications are used.
   b. generic drugs are substituted for brand-name drugs.
   c. patients begin using a new medication.
   d. medications are taken for just one or two days.
4. An important difference between medications and herbal products that reach the marketplace is that:
   a. medications that cause adverse effects cannot be sold.
   b. medications are subject to contamination with toxic metals, molds, and bacteria.
   c. herbal products are not required to prove safety and effectiveness.
   d. herbal products must provide standard amounts of active ingredients.
5. An important step that health practitioners can take to limit the risk of medication-related side effects is to:
   a. recommend use of over-the-counter drugs instead of prescription medications.
   b. encourage use of herbal supplements rather than prescription medications.
   c. advise patients to take medications separately from meals.
   d. ask patients to fully describe the types and amounts of medications and dietary supplements they are using.
6. Examples of medication-related symptoms that can significantly limit food intake include:
   a. ringing in the ears.
   b. persistent nausea and vomiting.
   c. insomnia.
   d. skin rash.
7. Factors that typically interfere with drug absorption include:
   a. binding between drugs and food components.
   b. use of antacid therapies.
   c. a rapid stomach-emptying rate.
   d. all of the above.
8. Compounds in grapefruit juice:
   a. bind to antibiotics, reducing absorption.
   b. cause excessive drug excretion.
   c. strengthen the effects of certain drugs.
   d. alter acidity in the stomach, impairing drug absorption.
9. Vitamin K consumption should be consistent in patients using:
   a. tetracycline.
   b. isoniazid.
   c. warfarin.
   d. lithium.
10. People who use MAO inhibiters must limit consumption of:
   a. whole milk and yogurt.
   b. aged cheeses.
   c. dark green leafy vegetables.
   d. grapefruit juice.

Anemia in Illness

© A.J.Photo/Photo Researchers, Inc.

Anemia—a reduction of red blood cells that lowers the oxygen-carrying capacity of the blood—is frequently the first sign of illness and may be the disorder that initially drives an individual to seek medical attention. Anemia is associated with a great number of diseases and is common among hospital patients: some 20 to 40 percent exhibit some degree of anemia.[1] Earlier chapters in this textbook described some of the relationships between anemia and nutrient deficiencies. This highlight explains how and why anemia develops during the course of illness. The glossary below defines relevant terms.

Overview of Anemia

Anemia develops when red blood cells (also called *erythrocytes*) are unable to be produced in sufficient numbers, are too quickly destroyed, or are lost due to bleeding. Because red blood cells contain the hemoglobin that supplies oxygen to tissues, their absence can result in fatigue and reduced stamina. The deficiency of oxygen in tissues is the main stimulus for the production of additional red blood cells.

Red Blood Cell Production

The production of red blood cells **(erythropoiesis)** takes place in the bone marrow, which is a soft tissue found in certain types of bone. The process begins when kidney cells sense the low oxygen content of blood and release the hormone **erythropoietin** (see Figure H19-1 on p. 658). Erythropoietin travels to the bone marrow, where it stimulates precursor cells (stem cells) to divide and differentiate into red blood cells. The cells that are released from the bone marrow are immature red blood cells called **reticulocytes.** Reticulocytes develop into mature red blood cells over a 24- to 48-hour period while they circulate in the bloodstream.

Nutritional Anemias

The nutrient deficiencies that most frequently upset red blood cell production are those of iron, folate, and vitamin B_{12}. Iron is required for hemoglobin production, and deficiency results in **microcytic anemia,** characterized by small, hypochromic cells (see p. 446). Vitamin B_{12} and folate participate in DNA synthesis, and deficiency of either nutrient leads to **macrocytic anemia,** characterized by large immature cells (see pp. 343–344).

Other nutrient deficiencies may cause anemia, although not as frequently. Vitamin E helps to maintain cell membrane integrity, and its deficiency is associated with **hemolytic anemia** (red blood cell breakdown). Vitamin B_6 plays a role in hemoglobin production, and a deficiency can sometimes cause microcytic anemia. Vitamin C supports blood vessel integrity; fragile and bleeding capillaries may result from deficiency. Protein-energy malnutrition leads to anemia because red blood cell development depends on protein synthesis. Although nutrient deficiencies may result from dietary inadequacy, they can also arise during the course of illness due to the effects of disease on intestinal absorption, nutrient metabolism, and nutrient losses.

Identifying Causes of Anemia

Identifying the cause of anemia is sometimes quite challenging. In some cases, anemia may be a well-known consequence of disease, as when renal failure impairs the synthesis of the hormone

GLOSSARY

anemia of chronic disease: anemia that develops in persons with chronic illness; may resemble iron-deficiency anemia even though iron stores are often adequate.

aplastic anemia: anemia characterized by the inability of bone marrow to produce adequate numbers of blood cells. Causes include genetic defects, viruses, radiation treatment, and drug toxicity.

erythropoiesis (eh-RIH-throh-poy-EE-sis): production of red blood cells within the bone marrow.

erythropoietin (eh-RIH-throh-POY-eh-tin): a hormone produced by kidney cells that stimulates red blood cell production.

hemolytic (hee-moe-LIH-tic) **anemia:** anemia characterized by the breakdown of red blood cells.

macrocytic anemia: anemia characterized by large red blood cells, as occurs in folate and vitamin B_{12} deficiency; also called **megaloblastic anemia.**

microcytic anemia: anemia characterized by small, hypochromic (pale) red blood cells, as occurs in iron deficiency.

peripheral blood smear: a blood sample spread on a glass slide and stained for analysis under a microscope. *Peripheral* refers to the use of circulating blood rather than tissue blood.

reticulocytes: immature red blood cells released into blood by the bone marrow.

FIGURE H19-1 Erythropoiesis

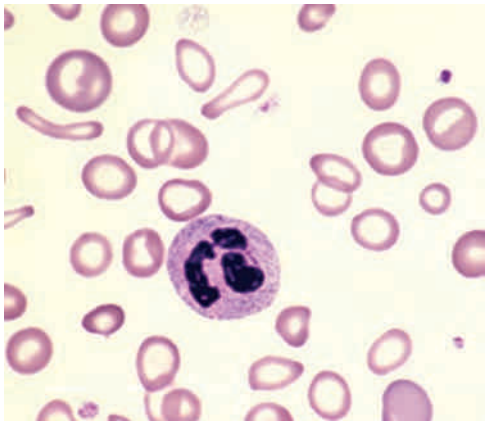
erythropoietin. When anemia develops rapidly, blood loss is often the cause, whereas a more gradual onset suggests malnutrition, chronic illness, or slow, chronic bleeding. The results of laboratory tests provide valuable clues, although conditions such as dehydration and inflammation can influence the values. Laboratory results are especially difficult to analyze if several disturbances are present simultaneously. A **peripheral blood smear** (see the photo) is often used to study abnormalities in red blood cell shape and may also reveal an underlying cause.



© Dr. Gladden Willis/Visuals Unlimited

A peripheral blood smear provides information about the number and shape of blood cells.

Nutritional Anemias in Illness

There are various ways in which illnesses can lead to iron, folate, or vitamin B_{12} deficiencies, the main causes of the nutritional anemias. Blood loss, common to many illnesses, is a primary cause of iron deficiency. Some illnesses may result in a reduction in food intake, as discussed in Chapter 17. The liver's stores of iron and vitamin B_{12} are often adequate to prevent deficiencies during transient illnesses, but reserves of folate are limited; thus a folate deficiency can develop within a few months if dietary intakes are low. If several nutrient deficiencies occur simultaneously, it may be difficult to identify the cause of anemia using standard blood tests (see Appendix E) because both macrocytic and microcytic anemia may be present.

Blood Loss

As mentioned, blood loss can eventually lead to iron deficiency. Unfortunately, slow, chronic bleeding may be difficult to identify before anemia develops.[2] Gastrointestinal conditions often cause bleeding; examples include peptic ulcers, inflammatory bowel conditions, and gastrointestinal varices (enlarged veins) that develop in advanced liver disease. Excessive bleeding can accom-

pany coagulation disorders, which are usually due to liver disease, genetic defects, or vitamin K deficiency. Frequent blood draws or surgical procedures also contribute to blood loss.

Nutrient Malabsorption

Chapter 24 explains how disorders that damage the small intestine can lead to nutrient malabsorption. Diseases like Crohn's disease and celiac disease can destroy intestinal mucosa and reduce the absorption of all nutrients. Iron is primarily absorbed in the duodenum and upper jejunum, and its absorption is impaired by conditions that reduce hydrochloric acid secretion or result in surgical resection (removal) of the upper intestine. Resection of the stomach or ileum can hasten the onset of vitamin B_{12} deficiency because both organs have roles in vitamin B_{12} absorption: you may recall from Chapter 10 that the stomach produces a protein (called *intrinsic factor*) needed for vitamin B_{12} absorption and that the ileum is the site of vitamin B_{12} absorption.

Anemia of Chronic Disease

Chronic disease itself can cause anemia, and anemia is sometimes the initial sign that chronic disease is present.[3] In fact, the **anemia of chronic disease** is the most common type of anemia affecting hospitalized patients and patients with chronic illnesses.[4] This type of anemia usually occurs in individuals who have chronic infections, inflammatory conditions, autoimmune disorders, or cancer. Although often a mild form of anemia, it can progress and become severe enough to require blood transfusions.[5]

The anemia of chronic disease is characterized by alterations both in the distribution of iron among tissues and in the rates of red blood cell production and destruction. As a result of the inflammatory response, macrophages in the liver, spleen, and bone marrow sequester iron, making it unavailable for erythropoiesis and hence slowing the rate of production of new red blood cells. In addition, red blood cells are destroyed more rapidly than usual, and the reduced production of red blood cells cannot keep pace. Finally, iron absorption is impaired, possibly because intestinal cells inhibit iron's release into blood. Eventually, outright iron deficiency may result from inadequate iron absorption.[6]

Blood tests help to distinguish between the anemia of chronic disease and iron-deficiency anemia (see Table H19-1). The combination of low serum iron and low total iron-binding capacity suggests the anemia of chronic disease rather than iron deficiency. In addition, serum ferritin levels are normal or elevated, whereas they are typically low in iron deficiency. Diagnosis is more complicated if both types of anemia are present.[7]

TABLE H19-1 Laboratory Tests for Evaluating Iron Deficiency and Anemia of Chronic Disease

Laboratory Test	Effect of Iron Deficiency	Effect of Chronic Disease
Red blood cell (RBC) size and number	Microcytic; reduced RBC count	Normocytic or microcytic; reduced RBC count
Serum iron	Low	Low
Serum ferritin	Low	Normal or elevated
Serum transferrin	Elevated	Low
Total iron-binding capacity	High	Low
Bone marrow iron	Low	Normal or elevated

Medications and Anemia

Anemia is among the adverse effects that may result from medication use. Medications can alter nutrient metabolism, can impair blood coagulation and erythropoiesis, and sometimes lead to increased red blood cell destruction. Because the life span of red blood cells is about 120 days, the long-term use of medications is more likely to result in anemia than is short-term use.

Drug-Nutrient Interactions

As Chapter 19 described, there are numerous ways in which medications can alter nutrient metabolism; the most common are listed in Table 19-4 on p. 649. A number of medications are known to influence the absorption or metabolism of folate and lead to macrocytic anemia. Sulfasalazine (used for ulcerative colitis) and some anticonvulsant drugs inhibit folate absorption, and methotrexate (an immunosuppressive), triamterene (a diuretic), and pyrimethamine (an antimalarial) interfere with folate metabolism.[8] If a medication is known to result in deficiency, nutrient supplementation is usually recommended as an adjunct therapy.

Impaired Coagulation

Anticoagulants, which are prescribed specifically to reduce blood clotting, sometimes lead to excessive bleeding. These medications work by interfering with one of the steps involved in blood clotting, such as platelet function, vitamin K function, or the synthesis of clotting proteins. Other than anticoagulants, drugs that impair coagulation include aspirin and other nonsteroidal anti-inflammatory drugs (NSAIDs), acetaminophen, cimetidine (Tagamet), ranitidine (Zantac), and thiazide diuretics.[9] The anticoagulant effects may be augmented if several of these drugs are used simultaneously. Sometimes the slow, chronic bleeding that develops when these drugs are taken may go unnoticed until excessive blood loss has occurred.

Aplastic Anemia

Many classes of drugs are associated with **aplastic anemia,** a type of anemia that occurs when the bone marrow fails to produce adequate numbers of blood cells. The categories of drugs associated with aplastic anemia include anticonvulsants, antibiotics, antidiabetic drugs, diuretics, antithyroid drugs, and anticancer agents.[10] Aplastic anemia can also be caused by a genetic defect or may result from viral infections or exposure to toxins.

Hemolytic Anemia

Some patients may develop hemolytic anemia as a result of drug interactions with red blood cells. For example, a drug may alter the red blood cell membrane in such a way that a component of the membrane becomes an antigen and induces an antibody response that destroys the cell.[11] Several types of antibiotics, including penicillin and cephalosporin, may cause this type of response. Withdrawal of the drug can eventually reverse the anemia, and sometimes medications are given to suppress the immune response.

In conclusion, anemia is a disorder associated with many diseases, and it may also be caused by disease treatment. When anemia occurs during illness, its causes must be investigated before it leads to complications that worsen prognosis. The medical history, blood tests, and peripheral blood smears may all help to determine the reasons why anemia has developed.

Nutrition in the Clinical Setting

Patients are often too sick to obtain the energy and nutrients they need by consuming foods. In such cases, enteral nutrition support can help many patients regain health. Because some enteral formulas are common grocery items, patients usually feel comfortable using them as oral supplements or as meal substitutes. Tube feedings, however, are unfamiliar to most people, and patients and caregivers may be resistant at first. Showing understanding and carefully explaining the procedure can help to alleviate patients' concerns.

CHAPTER 20

Enteral Nutrition Support

CHAPTER OUTLINE

Enteral Formulas • Types of Enteral Formulas • Formula Characteristics

Enteral Nutrition in Medical Care • Oral Use of Enteral Formulas • Indications for Tube Feedings • Feeding Routes • Formula Selection • Meeting Water Needs

Administration of Tube Feedings • Safe Handling • Initiating and Progressing a Tube Feeding • Medication Delivery through Feeding Tubes • Tube Feeding Complications • Transition to Table Foods

HIGHLIGHT 20 Inborn Errors of Metabolism

Some illnesses may interfere with eating, digestion, or absorption to such a degree that conventional foods cannot supply the necessary nutrients. In such cases, **nutrition support**—the delivery of formulated nutrients (prepared nutrient solutions)—can meet a patient's nutritional needs. **Enteral nutrition** provides nutrients using the gastrointestinal (GI) tract. Enteral nutrition includes oral diets or supplements, but the term more often refers to the use of tube feedings, which supply nutrients directly to the stomach or intestine via a thin, flexible tube. **Parenteral nutrition,** discussed in Chapter 21, provides nutrients intravenously to patients who do not have adequate gastrointestinal function to handle enteral feedings. If the GI tract remains functional, enteral nutrition support is usually preferred, partly to avoid the expense and complications associated with intravenous feedings and partly to preserve healthy GI function.

If gastrointestinal function is normal and a poor appetite is the primary nutrition problem, enteral formulas are generally provided as an oral supplement to the usual diet. If patients cannot consume enough food or drink enough formula to meet nutrient needs, tube feedings are often used to deliver the required nutrients.

nutrition support: the delivery of formulated nutrients via a feeding tube or intravenous infusion.

enteral (EN-ter-al) **nutrition:** the provision of nutrients using the GI tract, including the use of tube feedings and oral diets.

parenteral (par-EN-ter-al) **nutrition:** the intravenous provision of nutrients that bypasses the GI tract.
- **par** = beside
- **entero** = intestine

Enteral Formulas

Over 100 enteral formulas are currently marketed.[1] Most formulas can supply all of an individual's nutrient requirements when consumed in sufficient volume, a necessity for the patient who is using a tube feeding or oral liquid diet for more than a few days. Thus, an enteral formula can be considered a liquid form of a standard or modified diet.

Several enteral products are sold in pharmacies and grocery stores for home use; examples include Ensure, Boost, and Carnation Instant Breakfast. These

© 2000 C. C. Duncan/Medical Images Inc.

Patients can drink enteral formulas when they are unable to consume enough food from a conventional diet.

◆ Reminder: The *macronutrients* are carbohydrates, fats, and proteins.

products are used as dietary supplements by people who have trouble meeting nutritional needs or as convenient meal replacements by healthy individuals. The products are available in ready-to-drink liquid form or in powdered forms that must be reconstituted with water or milk.

Types of Enteral Formulas

Enteral formulas are categorized according to their macronutrient sources. ◆ **Standard formulas** usually contain intact proteins and polysaccharides, whereas **elemental formulas** contain macronutrients that have been broken down to some extent and require less digestion. **Specialized formulas** are designed to meet the specific needs of certain diseases. When an ideal formula is unavailable, a **modular formula** can be prepared in the hospital pharmacy by combining individual macronutrient preparations (called *modules*). Examples of enteral formulas are provided in Appendix K.

Standard Formulas Standard formulas, also called *polymeric formulas,* are provided to individuals who can digest and absorb nutrients without difficulty. They contain intact proteins extracted from milk or soybeans or a combination of **protein isolates** (proteins isolated from foods). The carbohydrate sources include modified starches, glucose polymers (such as maltodextrin), and sugars. A few formulas, called **blenderized formulas,** are made from whole foods and derive their protein primarily from pureed meat or poultry.

Elemental Formulas Elemental formulas, also called *hydrolyzed, chemically defined,* or *monomeric formulas*, are prescribed for patients who have compromised digestive or absorptive functions. Elemental formulas contain proteins and carbohydrates that have been partially or fully broken down to fragments that require little (if any) digestion. The formulas are often low in fat and may contain **medium-chain triglycerides (MCT)** to ease digestion and absorption. Table 20-1 compares the sources of macronutrients in standard and elemental formulas.

Specialized Formulas Specialized formulas, also called *disease-specific formulas,* are designed to meet the specific nutrient needs of patients with particular illnesses. Products have been developed for individuals with liver, kidney, and lung diseases; glucose intolerance; and metabolic stress. Disease-specific formulas are generally expensive, and their effectiveness is controversial.

Modular Formulas Modular formulas, created from individual macronutrient preparations called *modules,* are prepared for patients who require specific nutrient combinations to treat their illnesses. Vitamin and mineral preparations are

standard formulas: enteral formulas that contain mostly intact proteins and polysaccharides; also called *polymeric formulas.*

elemental formulas: enteral formulas that contain carbohydrates and proteins that are partially or fully hydrolyzed; also called *hydrolyzed, chemically defined,* or *monomeric formulas.*

specialized formulas: enteral formulas designed to meet the nutrient needs of patients with specific illnesses; also called *disease-specific formulas.*

modular formulas: enteral formulas prepared in the hospital from *modules* that contain single macronutrients; used for people with unique nutrient needs.

protein isolates: proteins that have been isolated from foods.

blenderized formulas: enteral formulas that are prepared by using a food blender to mix and puree whole foods.

medium-chain triglycerides (MCT): triglycerides that contain fatty acids that are 8 to 10 carbons in length. MCT do not require digestion and can be absorbed in the absence of lipase or bile.

TABLE 20-1 Macronutrient Sources in Standard and Elemental Formulas

Type of Formula	Carbohydrate Sources	Protein Sources	Fat Sources
Standard formulas	Corn syrup solids Hydrolyzed cornstarch Sucrose Fructose	Intact proteins, such as casein, whey, lactalbumin, and soy protein isolates Milk protein concentrate Egg white	Vegetable oils (such as corn oil, soybean oil, and canola oil) MCT Palm kernel oil
Elemental formulas	Hydrolyzed cornstarch Maltodextrin Fructose	Hydrolyzed casein, whey, lactalbumin, or soy protein Crystalline amino acids	Vegetable oils (such as corn oil, soybean oil, and canola oil) MCT

NOTE: MCT = medium-chain triglycerides

also included in these formulas so that they can meet all of a person's nutrient needs. In some cases, one or more modules are added to other enteral formulas to adjust their nutrient composition.

Formula Characteristics

The varying nutrient and energy densities in enteral formulas allow them to meet the needs of patients while providing different volumes of fluid. The fiber content influences fecal bulk, colonic function, and blood glucose control. These properties affect the administration of tube feedings, as well as the side effects that patients may experience.

Macronutrient Composition The percentages of protein, carbohydrate, and fat vary substantially among enteral formulas. The protein content of most formulas ranges from 12 to 20 percent of total kcalories.[2] Note that protein needs are high in patients with severe metabolic stress, whereas protein restrictions are necessary for patients with kidney disease. Carbohydrate and fat provide most of the energy in enteral formulas; standard formulas generally provide 40 to 60 percent of kcalories from carbohydrate and 30 to 40 percent of kcalories from fat.[3]

Energy Density The energy density of enteral formulas ranges from 0.5 to 2.0 kcalories per milliliter of fluid. Standard formulas typically provide 1.0 to 1.2 kcalories per milliliter and are appropriate for patients with average fluid requirements. Formulas that have higher energy densities can meet energy and nutrient needs in a smaller volume of fluid and thus benefit patients who have high nutrient needs or fluid restrictions. Individuals with high fluid needs can be given a formula with low energy density or be supplied with additional water via the feeding tube or intravenously.

Fiber Content The fiber content must be taken into account when selecting an enteral formula. Fiber-containing formulas can be helpful for normalizing intestinal function, treating diarrhea or constipation, and maintaining blood glucose control. Conversely, fiber-containing formulas are avoided in patients with acute intestinal conditions, pancreatitis, or procedures involving the intestines.

Osmolality **Osmolality** refers to the moles of osmotically active solutes *(osmoles)* per kilogram of solvent. ◆ An enteral formula with an osmolality similar to that of blood serum (about 300 milliosmoles per kilogram) is an **isotonic formula**, whereas a **hypertonic formula** has an osmolality greater than that of blood serum.

◆ Osmotically active solutes affect the movement of water across biological membranes (see p. 405).

Most enteral formulas have osmolalities between 300 and 700 milliosmoles per kilogram; generally, hydrolyzed formulas and nutrient-dense formulas have higher osmolalities than standard formulas. Most people are able to tolerate both isotonic and hypertonic feedings without difficulty.[4] When medications are infused along with enteral feedings, however, the osmotic load increases substantially and may contribute to the diarrhea experienced by many tube-fed patients.

IN SUMMARY

Enteral formulas are liquid diets that can meet all of a patient's nutritional needs. Standard formulas contain intact proteins and polysaccharides and are provided to patients who can digest and absorb nutrients without difficulty; elemental formulas meet the nutrient needs of patients with limited digestive and absorptive functions. Specialized formulas are available for use in patients with specific diseases. Modular formulas, which contain individual macronutrients, can be used to modify other formulas. Formulas differ in their macronutrient composition, energy density, fiber content, and osmolality. Most people can tolerate isotonic and hypertonic formulas without difficulty.

osmolality (OZ-moe-LAL-ih-tee): the concentration of osmotically active solutes in a solution, expressed as milliosmoles (mOsm) per kilogram of solvent.

isotonic formula: a formula with an osmolality similar to that of blood serum (about 300 milliosmoles per kilogram).
- **iso** = equal
- **tono** = pressure

hypertonic formula: a formula with an osmolality greater than that of blood serum.

Enteral Nutrition in Medical Care

A person with a functioning GI tract who cannot meet nutrient needs with conventional foods alone may be a candidate for enteral nutrition support. Enteral feedings are preferred over intravenous feedings because they help to stimulate or maintain gut function, cause fewer complications, and are less costly.[5] Similarly, oral feedings are preferred to tube feedings when the person is able to drink enteral formulas, because drinking the formulas prevents the stress, complications, and expense associated with tube feedings. ◆

◆ A decision tree for selecting an appropriate feeding method is shown in Figure 21-1 on p. 688.

Oral Use of Enteral Formulas

As mentioned, enteral formulas can fully meet the nutritional needs of individuals who can consume only liquids or who require hydrolyzed nutrients. In most cases, however, patients drink enteral formulas to supplement their diets when they cannot consume enough food to meet their needs. Enteral formulas provide a reliable source of nutrients and add energy and protein to the diets of malnourished patients. Those who are weak or debilitated may also find it easier to manage formulas than meals.

When a patient drinks a formula, taste becomes an important consideration. Allowing patients to sample different products and flavors and select the ones they prefer helps to promote acceptance. The "How to" below offers additional suggestions for helping patients to accept and enjoy oral formulas.

Indications for Tube Feedings

Tube feedings are typically recommended for patients at risk of developing protein-energy malnutrition who are unable to consume adequate food or formula for at least seven days.[6] The following medical conditions may indicate the need for tube feedings:

- Severe swallowing disorders
- Impaired motility in the upper GI tract
- Gastrointestinal obstructions and **fistulas** that can be bypassed with a feeding tube
- Certain types of intestinal surgeries
- Mechanical ventilation
- Extremely high nutrient requirements

fistulas (FIST-you-luz): abnormal passages between organs or tissues (or between an internal organ and the body's surface) that permit the passage of fluids or secretions.

HOW TO Help Patients Accept Oral Formulas

People using enteral formulas are often quite ill and have poor appetites. Even when a person enjoys a formula, the taste can become monotonous in time. Hydrolyzed formulas are usually less palatable than standard formulas, and patients may find them difficult to drink. Health professionals can help by trying these suggestions:

- Let the patient sample different formulas that are appropriate for his or her needs, and use only those that the patient enjoys.
- Serve formulas attractively and remind patients to drink them. Formulas offered in a glass on an attractive plate may be more appealing than those served from a can with an unfamiliar name.
- If a patient finds the smell of a formula unappealing, it may help to cover the top of the glass with plastic wrap or a lid, leaving just enough room for a straw.
- Provide easy access. Keep the formula close to the patient's bed where it can be reached with little effort and within sight so that the patient is reminded to drink it. Patients who are very ill may lack the motivation to reach for the formula, let alone drink it.
- Try keeping the formula in an ice bath so that it will be cool and refreshing when the patient drinks it. Check with the patient to make sure the colder temperature is suitable.
- For patients with little appetite, offer the formula in smaller amounts that are easy to tolerate, and serve it more frequently during the day.
- If the patient stops enjoying the formula, recommend different flavors or try other formulas.

- Little or no appetite for extended periods, especially if the patient is malnourished
- Mental incapacitation due to confusion, neurological disorders, or coma

Contraindications for tube feedings include severe GI bleeding, high-output fistulas, **intractable** vomiting or diarrhea, complete intestinal obstruction, and severe malabsorption.[7] In addition, some clinical studies suggest that tube feedings are not always effective in some of the patient populations in which they are routinely used; thus, the decision to use tube feedings should be considered in light of the most recent research evidence.[8]

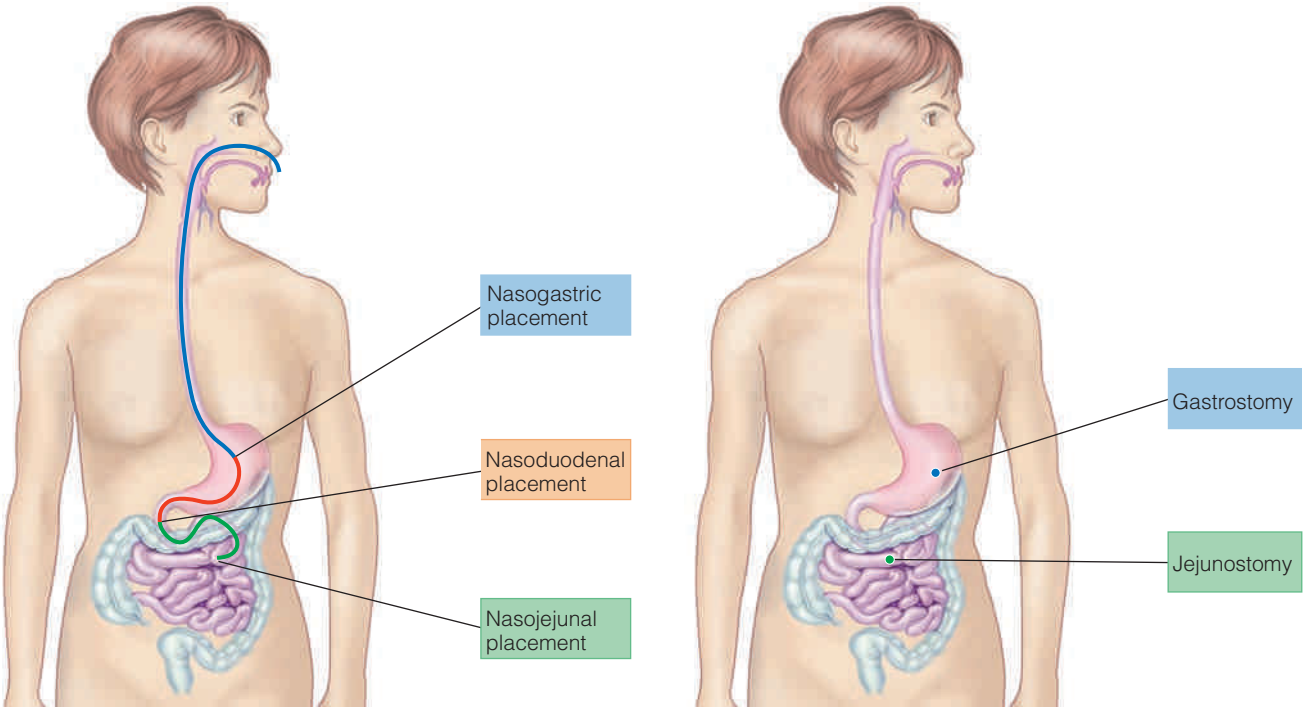
Feeding Routes

The feeding route chosen depends on the medical condition, expected duration of tube feeding, and potential complications of a particular route. Figure 20-1 illustrates the main feeding routes, and the Glossary of Tube Feeding Routes on p. 668 describes each route.

Gastrointestinal Access When a patient is expected to be tube-fed for less than four weeks, a **nasogastric** or **nasoenteric** route is generally chosen; for these routes, the feeding tube is passed into the GI tract via the nose. The patient is frequently awake during **transnasal** (through-the-nose) placement of a feeding tube. While the patient is in a slightly upright position with head tilted, the tube is inserted into a nostril and passed into the stomach (nasogastric placement), duodenum (**nasoduodenal** placement), or jejunum (**nasojejunal** placement). If the patient is awake and alert, he or she can swallow water to ease the tube's passage. The final position of the feeding tube tip is verified by abdominal X-ray or other means. In infants, **orogastric** placement, in which the feeding tube is

intractable: not easily managed or controlled.

FIGURE 20-1 Tube Feeding Routes



GLOSSARY OF TUBE FEEDING ROUTES

For each type of tube placement, the terms are listed in order from the upper to lower organs of the digestive system.

transnasal: through the nose. A *transnasal feeding tube* is one that is inserted through the nose.

- **nasogastric (NG):** tube is placed into the stomach via the nose.
- **nasoenteric:** tube is placed into the GI tract via the nose. (*Nasoenteric feedings* usually refer to *nasoduodenal* and *nasojejunal* feedings.)

nasoduodenal (ND): tube is placed into the duodenum via the nose.

nasojejunal (NJ): tube is placed into the jejunum via the nose.

orogastric: tube is placed into the stomach via the mouth. This method is often used to feed infants because a nasogastric tube can hinder the infant's breathing.

enterostomy (EN-ter-AH-stoe-mee): an opening into the GI tract through which a feeding tube can be passed.

- **gastrostomy** (gah-STRAH-stoe-mee): an opening into the stomach through which a feeding tube can be passed. A nonsurgical technique for creating a gastrostomy under local anesthesia is called *percutaneous endoscopic gastrostomy (PEG)*.
- **jejunostomy** (JE-ju-NAH-stoe-mee): an opening in the jejunum through which a feeding tube can be passed. A nonsurgical technique for creating a jejunostomy is called *percutaneous endoscopic jejunostomy (PEJ)*. The tube can either be guided into the jejunum via a gastrostomy or passed directly into the jejunum *(direct PEJ)*.

In a gastrostomy, the feeding tube accesses the GI tract through the skin.

passed into the stomach via the mouth, is sometimes preferred over transnasal routes; this placement allows the infant to breathe more normally during feedings.

When a patient will be tube-fed for longer than four weeks or if the nasoenteric route is inaccessible due to an obstruction or other medical reasons, a direct route to the stomach or intestine may be created by passing the tube through an **enterostomy,** an opening in the stomach **(gastrostomy)** or jejunum **(jejunostomy).** An enterostomy can be made by either surgical incision or needle puncture.

Selecting a Feeding Route As mentioned, transnasal access is usually preferred when the tube feeding duration is expected to be less than four weeks, and enterostomies are often appropriate when tube feedings are planned for longer periods. Gastric feedings, such as the nasogastric and gastrostomy routes, are preferred whenever possible. These feedings are more easily tolerated and less complicated to deliver than intestinal feedings because the stomach controls the rate at which nutrients enter the intestine. Gastric feedings are not possible, however, if patients have gastric obstructions or motility disorders that interfere with the stomach's ability to empty.

◆ Aspiration risk is high in patients with esophageal disorders, neurological diseases, and conditions that reduce consciousness or cause dementia.

aspiration: drawing in by suction or breathing; a common complication of enteral feedings in which foreign material enters the lungs, often from GI secretions or the reflux of stomach contents.

aspiration pneumonia: a lung disease resulting from the abnormal entry of foreign material; caused by either bacterial infection or irritation of the lower airways.

Gastric feedings are often avoided in patients at high risk of **aspiration,** ◆ a common complication in which formula or GI secretions enter the lungs, often from the backflow of stomach contents. **Aspiration pneumonia,** a lung disorder that is sometimes fatal, may result. Although health practitioners frequently administer nasoenteric feedings to minimize the possibility of aspiration, studies have not consistently shown that gastric feedings are associated with increased as-

TABLE 20-2 Comparison of Tube Feeding Routes[a]

Insertion Method and Feeding Site	Advantages	Disadvantages
Transnasal	Does not require surgery or incisions for placement.	Easy to remove by disoriented patients; long-term use may irritate the nasal passages, throat, and esophagus.
Nasogastric	Easiest to insert and confirm placement; feedings can often be given intermittently and without an infusion pump.	Highest risk of aspiration in compromised patients (controversial).[b]
Nasoduodenal and nasojejunal	Lower risk of aspiration in compromised patients[b]; allow for enteral nutrition earlier than gastric feedings following severe stress; may allow for enteral feeding when obstruction, fistulas, or other medical conditions prevent gastric feeding.	More difficult to insert and confirm placement; feedings require an infusion pump for administration; may take longer to reach nutrition goals.
Tube enterostomies	Allow lower esophageal sphincter to remain closed, reducing the risk of aspiration[b]; more comfortable than transnasal insertion for long-term use; site is not visible under clothing.	May require general anesthesia for insertion; require incisions; greater risk of complications from the insertion procedure; greater risk of infection; may cause skin irritation around the insertion site.
Gastrostomy	Feedings can often be given intermittently and without a pump; easier to insert than a jejunostomy.	Moderate risk of aspiration in high-risk patients.[b]
Jejunostomy	Lowest risk of aspiration[b]; allows for enteral nutrition earlier following severe stress; may allow for enteral feeding when obstructions, fistulas, or medical conditions prevent gastric feeding.	Most difficult to insert; feedings require an infusion pump for administration; may take longer to reach nutrition goals.

[a]Relative to other tube feeding routes. The actual advantages and disadvantages of different insertion procedures depend on the person's medical condition.
[b]The risk of aspiration associated with the different feeding routes is under investigation.

piration risk.[9] Table 20-2 summarizes the advantages and disadvantages of the various tube feeding routes.

Feeding Tubes Feeding tubes are made from soft, flexible materials (usually silicone, polyurethane, or polyvinyl) and come in a variety of lengths and diameters. The tube selected largely depends on the patient's age and size, the feeding route, and the formula's viscosity. In many cases, the tube selected is the smallest-diameter tube through which the formula will flow without clogging.

The outer diameter of a feeding tube is measured in **French units**, in which each unit equals $^1/_3$ millimeter; thus, a "12 French" feeding tube has a 4-millimeter diameter. ◆ The inner diameter depends on the thickness of the tubing material. Double-lumen tubes are also available; these allow a single tube to be used for both intestinal feedings and **gastric decompression**, a procedure in which the stomach contents of patients with motility disorders are removed by suction.

The thin wires protruding from the ends of these feeding tubes are stylets, which stiffen the tubes to ease insertion and are discarded thereafter. The Y-connector (shown here in orange) provides a port for administering water or medications without disrupting the feeding.

◆ 1 French = $^1/_3$ mm
12 French = 12 × $^1/_3$ mm = 4 mm

Formula Selection

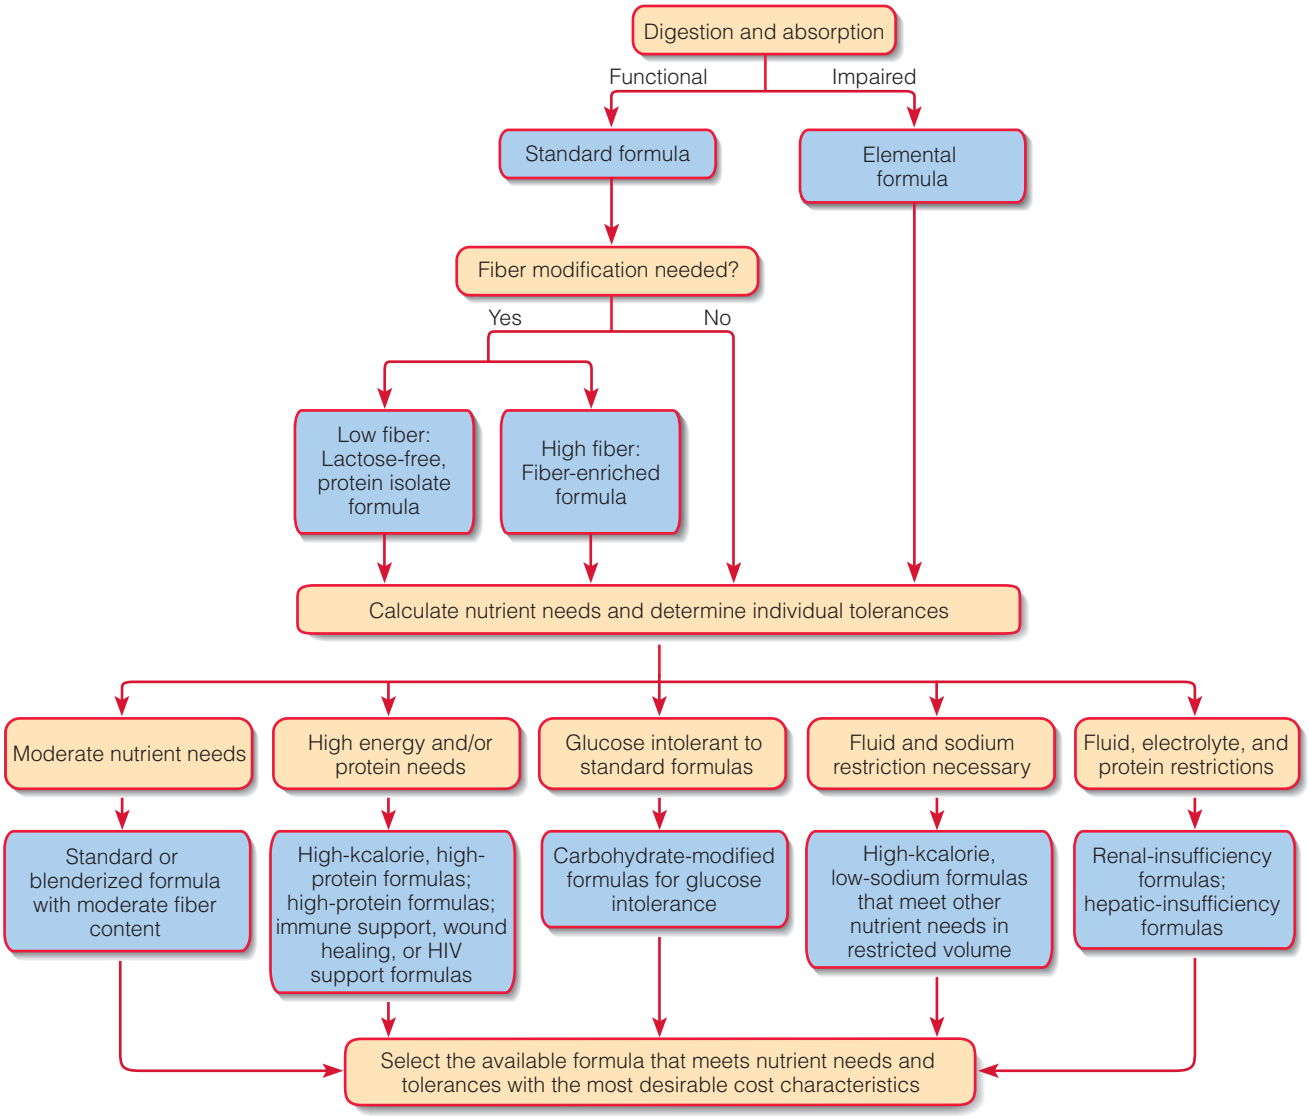
The formula is selected after careful assessment of the patient's medical problems, fluid and nutrition status, and ability to digest and absorb nutrients; some of the factors considered are shown in Figure 20-2 on p. 670. Generally, the best formula is one that meets the patient's medical and nutrient needs with the lowest risk of complications and the lowest cost. The vast majority of patients can use standard formulas. A person with a functional, but impaired, GI tract may require an elemental formula. Some nutrition-related criteria that may influence formula selection include:

- *Nutrient and energy needs.* As with patients consuming regular diets, an adjustment in macronutrient and energy intakes may be necessary for tube-fed patients. For example, patients with diabetes may need to control carbohydrate intake, critical care patients may have high protein and energy requirements, and patients with chronic kidney disease may need to limit their intake of protein and several minerals.

French units: units of measure used to indicate the size of a feeding tube's outer diameter; 1 French unit equals $^1/_3$ millimeter.

gastric decompression: the removal of the stomach contents (swallowed saliva, stomach secretions, and gas) of patients who have motility disorders or obstructions that prevent stomach emptying.

FIGURE 20-2 Selecting a Formula



- *Fluid requirements*. High nutrient needs must be met using the volume of formula a patient can tolerate. If fluids are restricted, the formula should have adequate nutrient content and energy density to deliver the necessary nutrients in the volume prescribed.
- *The need for fiber modifications*. The choice of formulas is narrower if fiber intake needs to be high or low. Formulas that provide fiber may be helpful for managing diarrhea, constipation, or hyperglycemia in some patients; other patients may need to avoid fiber due to an increased risk of GI obstructions.[10]
- *Individual tolerances (food allergies and sensitivities)*. Most formulas are lactose-free, because many patients who need enteral formulas have some degree of lactose intolerance. Many formulas are also gluten-free and can accommodate the needs of individuals with celiac disease (gluten sensitivity).

Health care facilities stock a limited number of formulas, so formula selection is limited by availability. Initially, the medical staff may make an educated guess as to the best formula based on the criteria previously mentioned, and the decision can be reappraised based on the patient's response to the formula. Note that

few research studies have evaluated the effectiveness of the various specialized formulas,[11] so their additional expense may be difficult to justify.

Meeting Water Needs

Although water needs vary, ◆ many adults require about 2000 milliliters (about 2 quarts) of water daily. Fluids may be restricted in persons with kidney, liver, or heart disease. Additional water is required in patients with fever, high urine output, diarrhea, excessive sweating, severe vomiting, fistula drainage, high-output ostomies, blood loss, or open wounds.

In alert adults, thirst is often a good indicator of water needs. People who complain of thirst may be given more water unless medical orders restrict fluid intake. In the elderly, however, thirst may be slow to develop in response to dehydration. Health professionals routinely monitor patients' weight changes, record fluid intake and output, and measure urine specific gravity to evaluate hydration status. (Chapter 17 provides additional information about evaluating hydration.)

◆ To estimate fluid requirements in adults and children:
- Adults: allow 30 to 40 mL/kg; 25 to 30 mL/kg in older adults.
- Children: allow 50 to 60 mL/kg.
- Infants: allow 100 to 150 mL/kg.

Formula Water Content The water in formulas meets a substantial portion of water needs. Standard formulas contain about 85 percent water, or about 850 milliliters of water per liter of formula. Nutrient-dense formulas contain about 69 to 72 percent water; exact amounts can be obtained from the product label or manufacturer's information sheet. In addition to the water in formulas, water can be provided by flushing water separately through the feeding tube.

Routine Flushes To prevent clogging, feeding tubes are routinely flushed with 20 to 30 milliliters of warm water before and after each feeding and about every 4 hours when feedings are continued throughout the day. The water used for routine flushes should be included when estimating fluid intakes.

IN SUMMARY

Enteral formulas are provided to patients who need to consume liquid or elemental diets or who require tube feedings. A nasoenteric feeding route is preferred for short-term tube feedings, whereas enterostomies are used for longer-term feedings. Because the stomach delivers nutrients into the intestine at a controlled rate, gastric feedings are often preferred, although they are frequently avoided in patients at risk of aspiration. A chief concern in formula selection is the formula's ability to meet the patient's nutrient requirements. Formulas meet a substantial portion of the water requirements, and additional water can be provided by flushing water through the feeding tube.

Administration of Tube Feedings

After the feeding route and formula have been selected, attention turns to delivering the formula. The methods of tube feeding administration vary somewhat from one health care facility to the next. The procedures presented in the following sections are general guidelines.

Safe Handling

Individuals who are ill or malnourished often have suppressed immune systems, making them vulnerable to infection from foodborne illness. To prevent contamination, the personnel involved in preparing and delivering formulas should work in clean environments, using clean equipment and clean hands.

© Ed Eckstein/Phototake

In an open feeding system, the formula is transferred from its original packaging to a feeding container.

© Courtesy of Abbott Nutrition

In a closed feeding system, the formula is prepackaged in a container that can be attached to a feeding tube, such as the bottle shown on the left. The formula in the can at right can be used in an open feeding system.

◆ A gastric sample usually has a pH between 1 and 4. An intestinal sample should have a pH between 6 and 8.

open feeding system: a delivery system that requires the formula to be transferred from its original packaging to a feeding container before being administered through the feeding tube.

closed feeding system: a delivery system in which the formula comes prepackaged in a container that is ready to be attached to the feeding tube for administration.

Safety Guidelines As mentioned in earlier chapters, health care facilities have specific protocols for handling food products and formulas based on the potential hazards and critical control points in food preparation, referred to as *HACCP* (*Hazard Analysis and Critical Control Points*) systems. Personnel involved with preparing or delivering formula should be aware of the specific HACCP systems at their facility related to formula preparation and administration.

Feeding Systems Formulas are available in open feeding systems and closed feeding systems. With an **open feeding system,** the formula needs to be transferred from its original packaging to a feeding container. Examples include formulas that are packaged in cans or bottles, concentrates that need to be diluted, and powders that require reconstitution. In a **closed feeding system,** the formula is prepackaged in a container that can be connected directly to a feeding tube. Closed systems are less likely to become contaminated, require less nursing time, and can hang for longer periods of time than open systems. Although closed systems cost more initially, they may be less expensive in the long run by preventing bacterial contamination and thus avoiding the costs of treating infections.

At the Nursing Station After the formula reaches the nursing station, the nursing staff assumes responsibility for its safe handling. Hands should be carefully washed before handling formulas and feeding containers. Some facilities require that nonsterile gloves be worn whenever formulas are handled. The following steps can reduce the risk of formula contamination when using open feeding systems:

- Before opening a can of formula, clean the lid with a disposable alcohol wipe and wash the can opener with detergent and hot water. (Check HACCP protocols for details.) If you do not use the entire can at one feeding, label the can with the date and time it was opened.
- Store opened cans or mixed formulas in clean, closed containers. Refrigerate the unused portion of formula promptly.
- Discard unlabeled or improperly labeled containers and all opened containers of formula that are not used within 24 hours.

At the Bedside To reduce the risk of bacterial infections in tube-fed patients, the nurse should hang no more than an 8-hour supply of formula when using an open feeding system. The nurse should discard any formula that remains, rinse out the feeding bag and tubing, and add fresh formula to the feeding bag. A new feeding container and tubing (except for the feeding tube itself) is necessary every 24 hours.

For closed feeding systems, the hang time should be no longer than 24 to 48 hours. Contamination is more likely with the longer time periods.

Initiating and Progressing a Tube Feeding

Before starting a tube feeding, health practitioners can ease fears by fully discussing the procedure with the patient and family members, who may feel anxious about using a feeding tube. The discussion should address the reasons why tube feeding is appropriate and the benefits and risks of the procedure. The "How to" on p. 673 offers suggestions that may help ease the concerns of patients who may benefit from tube feeding.

Tube Placement Serious complications can develop if a transnasal tube is accidentally inserted into the respiratory tract or if formula or GI secretions are aspirated into the lungs. To minimize the risk of incorrect tube placement, clinicians often use X-rays to verify the position of the feeding tube before a feeding is initiated. Another technique is to test the pH of a sample of bodily fluid drawn into the feeding tube; recall that the pH of stomach fluid is much lower than the pH of

fluid obtained from the intestine or respiratory tract. ◆ After the tube's placement has been confirmed, the nurse secures the tube to the patient's nose and cheek with tape and monitors the position of the tubing throughout the day.

To reduce the risk of aspiration, the patient's upper body is elevated to at least a 30- to 45-degree angle during the feeding and for 30 minutes after the feeding whenever possible. The addition of blue food coloring to formula was formerly suggested as a means of identifying aspirated formula in lung secretions; however, this practice is now discouraged because several deaths have been attributed to its use.[12]

Formula Delivery A day's nutrient needs can be met by delivering relatively large amounts of formula several times per day **(intermittent feedings)** or smaller amounts continuously throughout the day **(continuous feedings).** A patient may also start on a continuous feeding schedule and gradually transition to intermittent feeding. Each method has specific uses, advantages, and disadvantages.

Intermittent feedings are best tolerated when they are delivered into the stomach (not the intestine). Generally, a total of about 250 to 400 milliliters is delivered over 20 to 40 minutes using a gravity drip method or an infusion pump. The exact amount is determined by dividing the volume of formula required for meeting a patient's nutrient needs into several daily feedings, as shown in the "How to" on p. 674. Because of the relatively high volume of formula delivered at a time, intermittent feedings may be difficult for some patients to tolerate, and the risk of aspiration may be higher than with continuous feedings. An advantage of intermittent feedings is that they are similar to the usual pattern of eating and allow the patient freedom of movement between meals.

intermittent feedings: delivery of about 250 to 400 milliliters of formula over 20 to 40 minutes.

continuous feedings: slow delivery of formula at a constant rate over an 8- to 24-hour period.

HOW TO Help Patients Cope with Tube Feedings

The thought of being "force-fed" is frightening to many people. Some may envision thick feeding tubes or fear that the procedure will be painful. Others may associate tube feedings with disabling injury or irreversible illness. Patients may be less apprehensive once they understand the insertion procedure, the expected duration of the tube feeding, and the strategic role that nutrition plays in recovery from disease. The pointers that follow can help health professionals prepare patients for transnasal tube feedings:

- Allow the patient to see and touch the feeding tube. Seeing firsthand that the tube is soft and narrow (only about half the diameter of a pencil) often alleviates anxiety.
- Show the patient how the feeding apparatus is attached to the feeding tube, and explain how the feeding will work. For young children, use dolls or stuffed toys to demonstrate tube insertion and feeding procedures.
- Explain that the patient remains fully alert during the procedure and helps pass the tube by swallowing. A numbing solution sprayed on the back of the throat minimizes discomfort and prevents gagging during the procedure.
- Tell the patient that once the tube has been inserted, people have no problem talking, and they become accustomed to the tube's presence within a few hours. In most cases, the patient can easily swallow foods and liquids with the tube in place. If permitted, favorite foods or beverages can still be enjoyed.
- Assure the patient that the tube feeding will be temporary, if such assurance is appropriate.

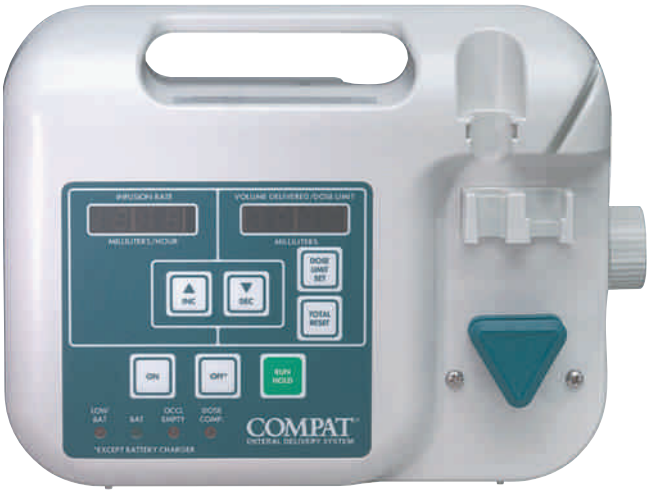
A tube feeding may be frightening for some patients, but others may be relieved to know that they can receive sound nutrition without any effort. As they feel better and begin to eat again, the volume of the feeding can be reduced and then tube feeding discontinued when oral intake is adequate.

Tube feedings may cause some patients to feel that they have lost control over an important aspect of their lives. They may also feel self-conscious about how the feeding tube looks or feel awkward when moving around with the equipment. A few measures can help:

- Involve patients in the decision-making and care process whenever possible. Patients can help to arrange their daily feeding schedules and can perform some of the feeding procedures themselves.
- Show patients how to manipulate the feeding equipment so that they can get out of bed and move around.
- Encourage patients to maintain contact with friends and keep busy with the hobbies and activities they enjoy. This measure is especially important for children, teens, and those on long-term feedings.

When caring for infants and children, keep the developmental age of the child in mind, and work with parents to ensure that appropriate feeding skills are mastered. Infants can be provided with a pacifier during feedings to help maintain the associations between sucking, swallowing, and fullness. When possible, the formula can be provided by bottle to an infant, or by spoon to a child, to further develop skills.

The more complex the procedure, the easier it becomes for health care professionals to focus on the procedure and disregard a patient's emotional response. No matter how many technicalities you have to keep in mind, remember to stay focused on the person receiving your care.



© Courtesy of Novartis Medical Nutrition

The delivery of intermittent and continuous feedings can be controlled with an infusion pump.

Rapid delivery of a large volume of formula into the stomach (250 to 500 milliliters in less than 20 minutes) is called a **bolus feeding.** This type of feeding may be given every 3 to 4 hours using a syringe. Bolus feedings can cause abdominal discomfort, nausea, and cramping in some patients, especially when the feeding is initiated. The risk of aspiration is also greater than with other methods of feeding. For these reasons, bolus feedings are used only in patients who are not critically ill.

Continuous feedings are delivered slowly and at a constant rate over a period of 8 to 24 hours. Continuous feedings are used in patients who receive intestinal feedings. This method of feeding is also recommended for critically ill patients, because delivering relatively small volumes at a time may reduce nausea, diarrhea, and possibly, the risk of aspiration. An infusion pump is required to ensure accurate and steady flow rates; consequently, the feedings can limit the patient's freedom of movement and are also more costly.

Formula Strength and Volume Formula administration techniques vary among institutions, so protocols should be reviewed carefully before working with patients. The patient's response can help in guiding formula delivery. Keep in mind that few studies have evaluated the various methods for initiating and progressing enteral feedings.

The formulas are typically provided full-strength, but they are occasionally diluted if the patient's fluid requirements are high and water needs cannot be met by other means.[13] In addition, dilution may sometimes be necessary to improve the flow of a viscous formula.

Intermittent feedings may start with 60 to 120 milliliters at the initial feeding and be increased by 30 to 60 milliliters at each feeding until the goal volume is reached. Continuous feedings may start at about 20 to 50 milliliters per hour and be raised by 10 to 25 milliliters per hour every 4 to 8 hours.[14] Concentrated formulas are often started at the slower rates. For both intermittent and continuous feedings, the delivery rate and amount of increase depend on the patient's tolerance to the formula. If the new rate is not tolerated, the rate of delivery progresses more slowly to give the person additional time to adapt. If a patient on intermittent feeding cannot tolerate the feeding, continuous feeding may be a better choice.

Checking Gastric Residuals When a patient receives a gastric feeding, the nurse regularly measures the **gastric residual volume** (the volume of formula remaining in the stomach after feeding) to ensure that the stomach is emptying properly. The gastric residual is measured by gently withdrawing the gastric contents through the feeding tube using a syringe, usually before each intermittent

bolus (BOH-lus) **feeding:** delivery of about 250 to 500 milliliters of formula in less than 20 minutes.

gastric residual volume: the volume of formula remaining in the stomach from a previous feeding.

HOW TO Determine the Formula Volumes to Administer in Tube Feedings

After selecting a formula that meets the patient's medical and nutrient needs, the clinician determines the volume of formula that meets those needs. Consider a patient who needs 2000 kcalories daily and is receiving a standard formula that provides 1.0 kcalorie per milliliter. The total volume of formula required would be 2000 milliliters per day:

$$x \text{ mL} \times 1.0 \text{ kcal/mL} = 2000 \text{ kcal}$$

$$x \text{ mL} = \frac{2000 \text{ kcal}}{1.0 \text{ kcal/mL}} = 2000 \text{ mL}$$

If the patient is to receive intermittent feedings 6 times per day, he will need about 330 milliliters of formula at each feeding:

$$2000 \text{ mL} \div 6 \text{ feedings} = 333 \text{ mL/feeding}$$

Alternatively, if he is to receive intermittent feedings 8 times per day, he will need 250 milliliters (or about 1 can of ready-to-feed formula) at each feeding:

$$2000 \text{ mL} \div 8 \text{ feedings} = 250 \text{ mL/feeding}$$

He will probably tolerate this volume of formula best if it is delivered over a 30-minute period at each feeding. If the patient is to receive the formula continuously over 24 hours, he will need about 85 milliliters of formula each hour:

$$2000 \text{ mL} \div 24 \text{ hours} = 83 \text{ mL/hr}$$

feeding and every 4 to 6 hours during continuous feedings.[15] Although opinions vary, some experts recommend that an evaluation be conducted if the gastric residual exceeds 200 milliliters and that feedings be withheld if it exceeds 500 milliliters. If the tendency to accumulate fluids persists, the physician may recommend intestinal feedings or begin drug therapy to stimulate gastric emptying.

Medication Delivery through Feeding Tubes

Patients receiving tube feedings sometimes require one or more medications that need to be delivered through feeding tubes. Because medications can interact with enteral formulas in the same ways that they interact with foods, potential diet-drug interactions must be considered. In addition, some medications may need to be exposed to the acidic stomach environment and thus cannot be administered via an intestinal feeding tube. Medications can also cause feeding tubes to clog. The "How to" below provides some guidelines about medication administration that may help to prevent complications.

Diarrhea Medications are a major cause of the diarrhea that frequently accompanies tube feedings. Diarrhea is especially associated with the administration of sorbitol-containing medications, laxatives, and some types of antibiotics.[16] The high osmolality of many liquid medications can cause diarrhea, so dilution of hypertonic medications may be helpful.

Medications and Continuous Feedings Continuous feedings are ordinarily stopped during the administration of medication so that the components of enteral formulas do not interfere with the medication's absorption. The feeding is typically halted for 15 minutes before and 15 minutes after medication delivery. Some medications may require a longer formula-free interval; for example, feedings need to be stopped for 1 to 2 hours before and after administering phenytoin, a medication that controls seizures.[17] In such cases, the formula's delivery rate needs to be increased so that the correct amount of formula can be delivered.

Tube Feeding Complications

Complications are a frequent occurrence during tube feedings. The following paragraphs discuss some of the common complications, which include gastrointestinal

HOW TO Administer Medications to Patients Receiving Tube Feedings

The pharmacist is your best resource for learning how and when medications can be administered via feeding tubes, especially when you are dealing with an unfamiliar medication. Check with the pharmacist to learn the following:

- Whether a particular medication is known to be incompatible with formulas.
- The proper timing of medication administration to avoid drug-nutrient interactions.
- For patients using intestinal feedings, whether a medication can be absorbed without exposure to stomach acid.
- Whether a liquid form of a medication is available, and if so, the appropriate dosage of the liquid form.
- If only tablets are available, whether the tablets can be crushed and mixed with water. Enteric-coated and sustained-release medications should not be crushed due to the potential for adverse effects.

In general, it is best to give medications by mouth instead of by tube whenever possible. In some cases, the injectable form of a medication may be the best option. For medications that must be given by feeding tube:

- Do not mix medications with enteral formulas. Do not mix medications together.
- Before administering medications, ensure that the feeding tube is placed correctly, that it is not clogged, and that the gastric residual is not excessive.
- Position the patient in a semiupright position (30 degrees or higher) to prevent aspiration.
- Flush the feeding tube with 15 to 30 milliliters of warm (body temperature) water before and after administering a medication. When more than one medication is administered, flush the tube with 5 milliliters of water after each medication is given.
- Use liquid forms of medications whenever possible. Dilute very viscous or hypertonic liquid medications with 10 to 30 milliliters of water before administering them through the feeding tube.
- If tablets are used, crush tablets to a fine powder and mix with 30 milliliters of warm water before administering.

problems, such as aspiration and diarrhea; mechanical problems directly related to the tube feeding process; and metabolic problems, such as biochemical alterations and nutrient deficiencies. Examples of these complications, along with preventive and corrective measures, are summarized in Table 20-3 on p. 677.

Gastrointestinal Complications Diarrhea may be caused by malabsorption problems, medications, bacterial overgrowth, malnutrition, or more rarely, hypertonic formulas. Constipation sometimes occurs due to dehydration, motility impairments, obstructions, and low-fiber intakes. Impaired gastric motility or inadequate functioning of the lower esophageal sphincter may result in aspiration of GI secretions or formula. Other GI complications include abdominal discomfort, nausea, and vomiting.

Mechanical Complications Mechanical problems include clogged feeding tubes, malfunctioning feeding pumps, and feeding tubes that become dislodged after placement. The feeding tube itself may be a physical irritant and may warrant a change to a different type of tubing or a different feeding route. Nasoenteric tube placement may cause a number of side effects, such as dry mouth from increased mouth breathing and reduced salivary secretions, blocked eustachian tubes and resultant middle ear infections, and sinus infections due to blocking of the sinus tract. Sometimes ostomies are associated with leakage of gastrointestinal secretions at the site of tube insertion.

Metabolic Complications Common metabolic complications include fluid imbalances (either dehydration or overhydration), electrolyte imbalances, and glucose intolerance. Routine blood tests may be necessary to monitor levels of potassium, phosphorus, sodium, and glucose until a patient has stabilized. Some patients may need insulin or medications to reverse hyperglycemia. Vitamin K and essential fatty acid deficiencies may result if formulas lacking these nutrients are used for a prolonged period.

Monitoring Tube Feedings Many complications of tube feeding can be prevented by choosing the most appropriate feeding route, formula, and delivery method. Attention to a patient's primary medical condition and medication use is important as well. The health practitioners responsible for the day-to-day care of the patient routinely monitor body weight, hydration status, and results of laboratory tests to detect problems before complications develop. Table 20-4 on p. 678 provides a monitoring schedule that may help with the early detection of common tube feeding problems.

Transition to Table Foods

Once the condition requiring a tube feeding resolves, the volume of formula can be tapered off as the patient gradually shifts to an oral diet. The steps in the transition depend on the patient's medical condition and the type of feeding the patient is receiving. Individuals using continuous feedings are often switched to intermittent feedings initially. In some patients, swallowing function may need to be evaluated before oral feedings begin. Patients receiving elemental formulas may begin the transition by using a standard formula, either orally or via tube feeding. If the patient has not consumed lactose for a month or longer, a low-lactose diet may be better tolerated. Oral intake should supply about two-thirds of estimated nutrient needs before the tube feeding is discontinued completely.[18] The Case Study on p. 678 allows you to consider the many factors involved in tube feedings.

TABLE 20-3 Causes and Prevention or Correction of Tube Feeding Complications

Complications	Possible Causes	Preventive/Corrective Measures
Aspiration of formula	Compromised lower esophageal sphincter, delayed gastric emptying	Use nasoenteric, gastrostomy, or jejunostomy feedings in high-risk patients; check tube placement; elevate head of bed during and for 45 minutes after feeding; check gastric residuals.
Clogged feeding tube	Formula too thick for tube	Select appropriate tube size; flush tubing with water before and after giving formula; use infusion pump to deliver thick formulas. Remedies that may help to unclog feeding tubes include flushes with warm water or solutions that contain pancreatic enzymes or bicarbonate; consult pharmacist for more options.
	Medications delivered through feeding tube	Use oral, liquid, or injectable medications whenever possible; dilute thick or sticky liquid medications with water before administering; crush tablets to a fine powder and mix with water (except enteric-coated or sustained-release medications); flush tubing with water before and after medications are given; give medications individually; do not add medications to the feeding container.
Constipation	Low-fiber formula	Provide additional fluids; use high-fiber formula.
	Lack of exercise	Encourage walking and other activities, if appropriate.
Dehydration and electrolyte imbalance	Excessive diarrhea	See items under *Diarrhea.*
	Inadequate fluid intake	Provide additional fluid.
	Carbohydrate intolerance	Use continuous drip administration of formula; monitor blood glucose; select a formula with a lower amount or different type of carbohydrate; provide a formula with a higher fat content.
	Excessive protein intake	Monitor blood electrolyte levels; reduce protein intake.
Diarrhea, cramps, abdominal distention	Bacterial contamination	Use fresh formula every 24 hours; store opened or mixed formula in a refrigerator; rinse feeding bag and tubing before adding fresh formula; change feeding apparatus every 24 hours; prepare formula with clean hands using clean equipment in a clean environment.
	Lactose intolerance	Use lactose-free formula in patients with current or potential lactose intolerance.
	Hypertonic formula	Use small volume of formula and increase volume gradually.
	Rapid formula administration	Use slow administration rate or use continuous drip feedings.
	Malnutrition/low serum albumin	Use small volume of dilute formula and increase volume and concentration gradually.
Hyperglycemia	Diabetes, hypermetabolism, drug therapy	Check blood glucose; slow administration rate; provide adequate fluids; select a formula with a lower amount or different type of carbohydrate; provide a formula with a higher fat content.
Nausea and vomiting	Obstruction	Discontinue tube feeding.
	Delayed gastric emptying	Check gastric residual; slow administration rate, use continuous drip feedings, or discontinue tube feeding.
	Intolerance to concentration or volume of formula	Use small volume of formula and increase volume and concentration gradually; use continuous drip feedings.
	Psychological reaction to tube feeding	Address patient's concerns.
Skin irritation at enterostomy site	Leakage of GI secretions and friction caused by the tube	Keep site clean; inspect area for redness, tenderness, and drainage; use protective skin cream.

NOTE: Many of the complications presented here can be caused by the patient's primary disorder or drug therapy rather than the tube feeding itself. In such a case, the corrective measure would include treatment of the disorder or a change in drug therapy. Additionally, other corrective measures that require a physician's order are not shown here.

TABLE 20-4 Monitoring Patients on Tube Feedings[a]

Before starting a new feeding:	Conduct a complete nutrition assessment. Check tube placement.
Before each intermittent feeding:	Check patient's position. Check tube placement. Check gastric residual volume. Flush feeding tube with water.
After each intermittent feeding:	Flush feeding tube with water.
Every hour:	Check infusion pump rate, when applicable.
Every 4 hours:	Check vital signs, including blood pressure, temperature, pulse, and respiration.
Every 4 to 6 hours of continuous feeding:	Check patient's position. Check gastric residual volume. Flush feeding tube with water.
Every day:	Check intake and output and hydration status. Check blood glucose; once stable, check blood glucose weekly (individuals without diabetes). Change feeding container and attached tubing. Clean feeding equipment.
Twice weekly:	Check body weight (check daily if patient is nutritionally unstable).
As necessary:	Observe patient for undesirable responses to tube feeding, such as delayed gastric emptying, nausea, vomiting, or diarrhea. Check results of laboratory tests. Check nitrogen balance.

[a]Guidelines vary among institutions. Monitoring frequency depends on the patient's medical condition. Patients beginning tube feedings and patients who are medically or nutritionally unstable need more intense monitoring.

CASE STUDY Graphics Designer Requiring Enteral Nutrition Support

Sharyn Eschler is a 24-year-old graphics designer who suffered multiple fractures when she fell from a cliff while hiking. She has been in the hospital for 2 weeks and has no appetite. Sharyn weighed 140 pounds upon her arrival in the hospital, but she has lost 8 pounds over the course of her hospitalization. Due to the nature of her injuries, she is in traction and is immobile, although the head of her bed can be elevated 45 degrees. From the diet history, it appears that Sharyn's nutrition status was adequate prior to hospitalization. The health care team agrees that nasoduodenal tube feeding should be instituted before her nutrition status deteriorates further. The standard formula selected for the feeding is lactose-free, and Sharyn's nutrient requirements can be met with 2200 milliliters of the formula per day.

1. What steps can be taken to prepare Sharyn for tube feeding? What are some general reasons why nasoduodenal placement of the feeding tube might be preferred over nasogastric placement?
2. What parameters should be monitored to ensure that Sharyn's fluid needs are being met? How can additional fluids be given? Estimate Sharyn's fluid needs using her current weight and the fluid intake range suggested in the margin on p. 671.
3. The physician's orders specify that the feeding should be given continuously over 18 hours. Using the method shown in the "How to" on p. 674, determine an appropriate feeding rate.
4. What steps can the health care team take to prevent aspiration? Describe precautions that should be taken if Sharyn is to receive medications through the feeding tube.
5. After three days of feeding, Sharyn develops diarrhea. Check pp. 675–676 and Table 20-3 to determine the possible causes. What measures can be taken to correct the diarrhea?

IN SUMMARY

To maximize the benefits of tube feedings, formulas should be prepared and administered using food safety techniques that minimize the risk of complications. Tube placement should be verified and monitored to reduce the risks of aspiration and inadvertent placement into the respiratory tract. Depending on the feeding route and medical condition, the formula can be delivered in bolus feedings, intermittently, or continuously. Medications should be given separately and accompanied by water flushes to prevent tube clogging. Complications of tube feedings can be gastrointestinal, mechanical, or metabolic in nature.

Clinical Portfolio

- Appendix K provides examples of enteral formulas on the market and lists their energy and macronutrient contents. Select one standard formula and one elemental formula from Tables K-1 and K-2, respectively. For the two formulas you selected, calculate the volume of formula that would meet the energy needs of a patient who requires about 1750 kcalories daily. Use these results in answering the following questions:

  a. What is the amount of protein, carbohydrate, and fat that the patient would obtain in a typical day? Determine the percentages of kcalories that come from carbohydrate and fat. Do these percentages fall within the Acceptable Macronutrient Distribution Ranges described in Chapter 1 (p. 18)?

  b. Tables J-1 and J-2 show the formula volumes that would meet the Reference Daily Intakes (RDI). Would the volumes you obtained meet typical vitamin and mineral needs?

- The administration of tube feedings requires attention to many technical details, which makes it easy to focus on the procedure rather than the patient. Imagine that your brother, sister, or a parent requires a transnasal tube feeding. How might this person react to the need for a tube feeding? How would you explain the benefits and possible problems associated with the procedure? Think about the ways you would want the health practitioner to help your relative.

NUTRITION ASSESSMENT CHECKLIST for People Receiving Tube Feedings

Medical History

Check the medical record for medical conditions that:

- Alter nutrient needs and influence the formula selection
- Influence the selection of tube placement sites (gastric versus intestinal) and feeding routes
- Suggest the length of time that the tube feeding will be needed

Monitor the medical record for complications or risks that may influence the formula selection or delivery technique, including:

- Aspiration
- Constipation
- Fluid and electrolyte imbalances
- Diarrhea
- Hyperglycemia
- Nausea and vomiting
- Skin irritation

Medications

Check medications for those that can cause side effects similar to the adverse effects associated with the tube feeding, such as:

- Nausea and vomiting
- Diarrhea
- Constipation
- GI discomfort

For medications delivered through the feeding tube, check:

- Form of medication and possible alternatives
- Viscosity of liquid medications
- Potential for diet-drug interactions

Dietary Intake

To assess nutritional adequacy, check to see whether:

- The formula is appropriate for patient's needs
- Supplemental water is provided to meet needs
- The formula is administered as prescribed

Anthropometric Data

Measure baseline height and weight, and monitor body weight regularly. If weight is not appropriate:

- Determine whether energy needs have been correctly assessed.
- Check to see if the formula is being delivered as prescribed.
- Check for signs of dehydration or overhydration.

Laboratory Tests

Check serum and urine tests for signs of:

- Fluid and electrolyte imbalances
- Glucose intolerance
- Adequacy of protein intake (serum protein levels)
- Improvement or deterioration of the medical condition

Physical Signs

Look for physical signs of:

- Dehydration or overhydration
- Delayed gastric emptying (gastric residual volume)
- Malnutrition

STUDY QUESTIONS

CENGAGENOW™

To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Characterize standard formulas, elemental formulas, specialized formulas, and modular formulas, and describe situations in which they are used. (pp. 664–665)
2. Discuss how macronutrient composition, energy density, fiber content, and osmolality vary in enteral formulas. (p. 665)
3. Identify reasons why oral intake of enteral formulas may be advised. Suggest ways for improving patient acceptance of formulas. (p. 666)
4. List the types of patients who may benefit from tube feedings. (pp. 666–667)
5. Describe the different tube feeding routes, and suggest reasons why each might be used. Discuss advantages and disadvantages of each. (pp. 667–669)
6. Identify measures that can help to prevent contamination of enteral formulas and equipment. (pp. 671–672)
7. Contrast the different methods of formula delivery, and discuss the possible advantages and disadvantages associated with each. Discuss how clinicians can help to relieve anxiety about tube feeding procedures. (p. 673–674)
8. Describe the problems that can occur when medications are delivered through feeding tubes. Suggest guidelines that can prevent these problems. (p. 675)
9. Discuss complications often associated with tube feedings. Summarize possible causes and some measures that can prevent or correct these complications. (pp. 676–677)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 681.

1. Which of the following statements is correct?
   a. Standard formulas contain whole proteins or protein isolates.
   b. Standard formulas contain free amino acids or small peptide chains.
   c. Modular formulas contain a mixture of proteins, carbohydrates, and fats.
   d. Elemental formulas may contain protein isolates or whole proteins.

2. *Osmolality* refers to an enteral formula's:
   a. energy density.
   b. nutrient density.
   c. fiber content.
   d. concentrations of molecules and ionic particles.
3. For a patient who is at high risk of aspiration and is not expected to be able to eat table foods for several months, an appropriate placement of a feeding tube might be:
   a. nasogastric.
   b. nasoenteric.
   c. gastrostomy.
   d. jejunostomy.
4. In selecting an appropriate enteral formula for a patient, the primary consideration is:
   a. formula osmolality.
   b. the patient's nutrient needs.
   c. availability of infusion pumps.
   d. formula cost.
5. An important measure that may prevent bacterial contamination in tube feeding formulas is:
   a. nonstop feeding of formula.
   b. using the same feeding bag and tubing each day.
   c. discarding opened containers of formula not used within 24 hours.
   d. adding formula to the feeding container before it empties completely.
6. Compared with intermittent feedings, continuous feedings:
   a. always require an infusion pump.
   b. allow greater freedom of movement.
   c. are more similar to normal patterns of eating.
   d. are associated with more GI side effects.
7. A patient needs 1800 milliliters of formula a day. If the patient is to receive formula intermittently every 4 hours, how many milliliters of formula will she need at each feeding?
   a. 225
   b. 300
   c. 400
   d. 425
8. The term that describes the volume of formula remaining in the stomach from a previous feeding is:
   a. residue.
   b. osmolar load.
   c. gastric residual.
   d. intermittent feeding.
9. The health professional using a feeding tube to deliver medications recognizes that:
   a. medications given by feeding tube generally do not cause GI complaints.
   b. medications can usually be added directly to the feeding container.
   c. enteral formulas do not interact with medications in the same way that foods do.
   d. thick or sticky liquid medications and crushed tablets can clog feeding tubes.
10. Tube feedings can gradually be discontinued when:
    a. discharge planning begins.
    b. the patient experiences hunger.
    c. the medical condition resolves.
    d. the patient is able to eat foods or drink formula in sufficient amounts.

Inborn Errors of Metabolism

© Miguel Gandert/Corbis

Chapter 20 described the use of enteral formulas for patients who are unable to meet their nutrient needs with conventional foods. Such is the case for individuals with some inborn errors of metabolism; for them, enteral formulas play a vital role in disease management. This highlight describes some inborn errors of metabolism and discusses the role of diet in two of these disorders: phenylketonuria and galactosemia. The accompanying glossary defines terms related to inborn errors of metabolism.

Inborn Errors of Metabolism

An **inborn error of metabolism** is an inherited trait, caused by a genetic **mutation,** that results in the absence, deficiency, or malfunction of a protein that has a critical metabolic role.[1] The protein may function as an enzyme, receptor, transport protein, or structural protein. When the body fails to make a protein, the functions that depend on that protein are impaired. For example, when an enzyme is missing or malfunctioning in a metabolic pathway that typically converts compound A to compound B, compound A will accumulate and compound B will not be made. The excess of compound A and the lack of compound B may have harmful effects. Furthermore, the imbalances in one pathway may affect other pathways and ultimately cause a number of metabolic and physiologic disturbances. The severity of the inborn error's effects are ultimately related to the degree of impairment caused by the altered or missing protein.

Treatment for Inborn Errors of Metabolism

Successful treatment for an inborn error of metabolism depends on the ability to screen newborns and diagnose metabolic diseases before irreversible damage can occur. After a genetic defect is identified, family members undergo **genetic counseling** to evaluate the likelihood that they may pass on the disorder to future offspring. During counseling, couples may learn about reproductive options such as artificial insemination, in vitro fertilization, or prenatal monitoring after conception.

Medical nutrition therapy is the primary treatment for many inborn errors that involve nutrient metabolism. Once the biochemical pathway affected by a mutation is identified, a health practitioner may be able to manipulate elements of the diet to compensate for deficiencies and excesses. Dietary intervention generally involves restricting substances that cannot be properly metabolized and supplying substances that cannot be produced. Thus, dietary changes may be able to improve outcomes of some inborn errors by:

- Preventing the accumulation of toxic metabolites
- Replacing nutrients that are deficient as a result of a defective metabolic pathway
- Providing a diet that supports normal growth and development and maintains health

GLOSSARY

cystic fibrosis: an inherited disorder that affects the transport of chloride across epithelial cell membranes; primarily affects the gastrointestinal and respiratory systems.

galactosemia (ga-LACK-toe-SEE-me-ah): an inherited disorder that affects galactose metabolism. Accumulated galactose causes damage to the liver, kidneys, and brain in untreated patients.

gene therapy: treatment for inherited disorders, in which DNA sequences are introduced into the chromosomes of affected cells, prompting the cells to express the protein needed to correct the disease.

genetic counseling: support for families at risk of genetic disorders; involves diagnosis of disease, identification of inheritance patterns within the family, and review of reproductive options.

hemophilia (HE-moh-FEEL-ee-ah): inherited bleeding disorders characterized by deficiency or malfunction of plasma proteins needed for clotting blood.

inborn error of metabolism: an inherited trait (one that is present at birth) that causes the absence, deficiency, or malfunction of a protein that has a critical metabolic role.

metabolites: products of metabolism; compounds produced by a biochemical pathway.

mutation: an inheritable alteration in the DNA sequence of a gene.

phenylketonuria (FEN-il-KEY-toe-NU-ree-ah) or *PKU:* an inherited disorder that affects the conversion of the essential amino acid phenylalanine to the amino acid tyrosine.

Nondietary therapies can treat some inborn errors of metabolism, although the options are somewhat limited. In some cases, the missing protein is infused; this is the primary means of treating **hemophilia,** caused by deficiency of one of the plasma proteins needed for clotting blood. Drug therapy is the main treatment for some inborn errors, including **cystic fibrosis** (discussed in Chapter 24), which is characterized by a defect that prevents normal chloride transport across cell membranes. Future approaches may include **gene therapy,** a treatment that introduces DNA sequences into the chromosomes of affected cells, prompting the cells to express the protein needed to correct the abnormality.

The following sections of this highlight present a sampling of inborn errors that benefit primarily from medical nutrition therapy. A classic example is phenylketonuria, a metabolic disorder that affects one's ability to metabolize the essential amino acid phenylalanine.

Phenylketonuria

One of many inborn errors affecting amino acid metabolism, **phenylketonuria (PKU)** affects approximately 1 out of every 10,000 births in the United States each year.[2] The screening of newborns for PKU is one of the most common genetic tests in the United States and many other countries. The early detection and treatment of PKU have successfully prevented most of the damaging consequences of this disorder.

The Error in PKU

In PKU, the missing or defective protein is a liver enzyme that converts the essential amino acid phenylalanine to the amino acid tyrosine (see Figure H20-1). Without this enzyme, phenylalanine and its **metabolites** (metabolic products) accumulate and damage the developing nervous system. The impairment in the metabolic pathway also prevents liver synthesis of tyrosine and tyrosine-derived compounds (such as the neurotransmitter epinephrine). Under these conditions, tyrosine becomes essential: the body cannot produce tyrosine, and therefore the diet must supply it.

Although PKU's most debilitating effect is on brain development, other symptoms may manifest if the condition is untreated. Infants with PKU may have poor appetites and grow slowly. They may be irritable or have tremors or seizures. Their bodies and urine may have a musty odor. Their skin may be unusually pale, and they may develop skin rashes. In older children and adults who discontinue treatment, neurological and psychological problems are common.

FIGURE H20-1 Biochemical Alterations in PKU

Normal:

Normally, the amino acid phenylalanine follows two pathways, one in the liver and the other in the kidneys. In the liver, the enzyme phenylalanine hydroxylase adds a hydroxyl group (OH) to produce the amino acid tyrosine. Tyrosine, in turn, produces melanin, the pigmented compound found in skin and brain cells; the neurotransmitters epinephrine and norepinephrine; and the hormone thyroxin. In the kidneys, enzymes convert phenylalanine to by-products that are excreted.

In the liver:

Phenylalanine —(Phenylalanine hydroxylase)→ Tyrosine → Melanin, Epinephrine, Norepinephrine, Thyroxin

In the kidneys:

Phenylalanine → Phenylpyruvic acid (a ketone body) → Other phenyl acids (excreted)

In PKU:

Individuals with PKU lack the liver enzyme phenylalanine hydroxylase, impairing conversion of phenylalanine to tyrosine. Phenylalanine accumulates in the liver and blood, reaching the kidneys in abnormally high concentrations. In the kidneys, an aminotransferase enzyme converts phenylalanine to the ketone body phenylpyruvic acid, which spills into the urine—thus the name phenylketonuria.

In the liver:

Phenylalanine (accumulates) —(Phenylalanine hydroxylase (deficient))→ Tyrosine (deficient)

In the kidneys:

Phenylalanine (accumulates) → Phenylpyruvic acid (accumulates) → Other phenyl acids (accumulate)

Detecting PKU

PKU is not evident at birth, but diagnosis in the first few days of life and early treatment prevent its devastating effects. For this reason, newborns are screened for PKU in all 50 states.[3] A standard blood test for phenylalanine is typically conducted by heel puncture, often after the infant has consumed several meals containing protein. Abnormal results require further testing. Before widespread newborn screening, infants with PKU demonstrated developmental delays (for example, inability to crawl) by six to nine months of age. By the time parents recognized the problem, the damage was irreversible.

Medical Nutrition Therapy for PKU

The only current treatment for PKU is a diet that restricts phenylalanine and supplies tyrosine so that the blood levels of these amino acids are maintained within safe ranges. Because phenylalanine is an essential amino acid, the diet cannot exclude it completely. Children with PKU need phenylalanine to grow, but they cannot handle excesses without detrimental effects. Therefore, their diets must provide enough phenylalanine to support growth and health but not so much as

© Ted Horowitz/Corbis

A simple blood test screens newborns for PKU—a common inborn error of metabolism.

to cause harm. The diets must also provide tyrosine, which is an essential nutrient for individuals with PKU. To ensure that blood concentrations of phenylalanine and tyrosine are close to normal, blood tests are performed periodically, and diets are adjusted when necessary. If the dietary treatment is conscientiously followed, it can prevent the symptoms described earlier. Adults must continue to follow the PKU diet as well to prevent deterioration in brain function.

The PKU Diet

Central to the PKU diet (for all ages) is the use of an enteral formula that is phenylalanine-free yet supplies energy, amino acids, vitamins, and minerals. In infants, the phenylalanine-free formula is supplemented with measured amounts of breast milk or regular infant formula, which provide the phenylalanine that an infant needs for growth. Low-phenylalanine infant formulas are also available and are useful for infants who meet most or all of their nutrient needs by consuming formula. Formula requirements need to be recalculated periodically to accommodate the growing infant's shifting needs for protein, phenylalanine, tyrosine, and energy.

Once food consumption begins, a phenylalanine-free formula supplies the needed amino acids, and foods that contain phenylalanine are carefully monitored. All proteins contain some phenylalanine; therefore, high-protein foods such as meat, fish, poultry, milk, cheese, legumes, and nuts (including peanut butter) are omitted. Fruits, vegetables, and cereals also contain phenylalanine, so only limited amounts are allowed. Low-protein flours and mixes are available for making low-phenylalanine breads, pasta, cakes, and cookies. Foods that do not contain phenylalanine, such as jams, jellies, and most sweeteners, can be used freely. Growth rates and nutrition status are monitored to ensure that the diet is adequate.

Parents and children may need to develop creative ways to make these diets enjoyable. The formula can be flavored or combined with fruits or juices to make smoothies or frozen juice bars. Sandwiches can include low-phenylalanine breads and fillings such as mashed bananas or avocados, shredded carrots and olives, or tomato slices with mayonnaise. Children often enjoy creating special recipes with permitted foods to make their choices more varied and to share meals with friends.

Continuing Dietary Restrictions

Lifelong adherence to a phenylalanine-restricted diet is currently recommended for all individuals with PKU. (Adults continue to use phenylalanine-free formulas, which generally provide about half of their protein and energy needs.) Elevated phenylalanine levels can adversely affect cognitive function at any age. Case studies have suggested that individuals with PKU who discontinue dietary management may have problems with attention span, concentration, and memory. It is especially important that women with PKU maintain safe phenylalanine concentrations during pregnancy. Elevated phenylalanine levels, especially during the first trimester, have been associated with mental retardation and organ malformations in the offspring of PKU mothers who have discontinued dietary treatment.[4]

Galactosemia

Galactosemia is an example of an inborn error of carbohydrate metabolism. Individuals with galactosemia are deficient in one of the enzymes needed to metabolize galactose, a sugar that is primarily found in milk products (recall that each lactose molecule contains a molecule of galactose). An accumulation of galactose can cause damage in multiple tissues. Infants with galactosemia who are given milk react with severe vomiting and liver jaundice within days of the initial feeding. Serious liver damage can develop and progress to symptomatic cirrhosis. Other complications may include kidney failure, cataracts, and brain damage. Treatment in the first weeks of life can prevent the most detrimental effects of galactose accumulation, but if treatment is delayed, the damage to the brain is irreversible.[5]

The Galactosemia Diet

The diet for galactosemia is much simpler than the diet for PKU. For one thing, galactose is not an essential nutrient. The galactosemia diet essentially eliminates galactose from the diet and does not need to provide a carefully determined amount of any nutrient, as the PKU diet does. In addition, dietary galactose is primarily obtained from lactose (the milk sugar), so the main focus of dietary treatment is the exclusion of milk and milk products. A

number of other foods that contain galactose in substantial amounts, such as organ meats and some legumes, fruits, and vegetables, must also be avoided or restricted. Patients receive food lists that identify the galactose content of common foods.

Infants diagnosed with galactosemia are given lactose-free formulas to meet their nutrient needs. Once a child can consume adequate amounts of regular foods, special formulas are unnecessary. However, care must be taken to ensure that the diet supplies adequate calcium.

Long-Term Complications

Although the early introduction of a galactose-restricted diet can eliminate the acute toxic effects of galactosemia, complications of the disease may develop despite an individual's compliance with diet therapy. For example, most patients experience delays in speech and language development. Ovarian failure occurs in up to 85 percent of women who have galactosemia.[6] In addition, some evidence suggests that IQ declines as a person with galactosemia ages. The reasons for these long-term complications are not fully understood.

As our scientific understanding of human genetics and biochemistry increases, more inborn errors of metabolism are being recognized. Mainstays of management for these diseases include effective diagnosis, early treatment, and control of environmental factors that cause toxicity. In some cases, dietary changes are central to treatment and can prevent serious complications. Not all inborn errors are easily treated, however. Future developments in biotechnology may someday allow medical practitioners to correct genetic errors using gene therapy.

Nutrition in the Clinical Setting

The science of medical nutrition was dramatically changed in 1968 by the demonstration that all nutrient needs could be met intravenously. Since then, health practitioners have had a way to feed people who otherwise might have died from malnutrition. Although intravenous feeding techniques have advanced considerably since 1968, parenteral nutrition remains expensive and is sometimes associated with serious complications. For these reasons, health practitioners subscribe to the adage "If the GI tract works, use it."

CHAPTER 21

Parenteral Nutrition Support

CHAPTER OUTLINE

Indications for Parenteral Nutrition

Parenteral Solutions • Parenteral Nutrients • Solution Preparation

Administering Parenteral Nutrition • Insertion and Care of Intravenous Catheters • Administration of Parenteral Solutions • Discontinuing Intravenous Feedings • Managing Metabolic Complications

Nutrition Support at Home • Candidates for Home Nutrition Support • Planning Home Nutrition Care • Quality-of-Life Issues

HIGHLIGHT 21 Ethical Issues in Nutrition Care

Chapter 20 described how enteral formulas can supplement or replace conventional foods to meet nutritional needs. Enteral formulas cannot be used when intestinal function is inadequate, however, and therefore the ability to meet nutrient needs intravenously is a lifesaving option for critically ill persons. Unfortunately, the procedure is costly and associated with a number of potentially dangerous complications. If the gastrointestinal (GI) tract is functional, enteral nutrition support is preferred, partly to avoid the expense and complications associated with intravenous feedings and partly to preserve healthy GI function. Figure 21-1 on p. 688 summarizes the decision-making process for selecting the most appropriate feeding method.

Indications for Parenteral Nutrition

As with other nutrition therapies, the decision to use parenteral nutrition is based on a thorough assessment of the patient's medical condition and nutrient needs. Generally, parenteral nutrition is indicated for patients who do not have functioning GI tracts and who are either malnourished or likely to become so. Parenteral support may also be of benefit if using the GI tract would cause harm to the patient, as when severe tissue damage in the small intestine requires bowel rest for an extended period. Thus, patients with the following conditions are often considered candidates for parenteral nutrition:

- Intestinal obstructions or fistulas
- Paralytic ileus (intestinal paralysis)
- Short-bowel syndrome (a substantial portion of the small intestine has been removed)
- Intractable vomiting or diarrhea
- Severe electrolyte, mineral, and glucose imbalances
- Severe pancreatitis

FIGURE 21-1 Selecting a Feeding Route

The peripheral veins can provide access to the blood for delivery of parenteral solutions.

peripheral veins: small-diameter veins that carry blood from the arms and legs.

central veins: large-diameter veins located close to the heart.

peripheral parenteral nutrition (PPN): a type of nutrition support in which intravenous feedings are delivered into peripheral veins.

osmolarity: the concentration of osmotically active particles in a solution, expressed as milliosmoles per liter (mOsm/L). *Osmolality* is an alternative expression of a solution's osmotic properties that is used in clinical practice and is expressed as milliosmoles per kilogram (mOsm/kg).

- Bone marrow transplants
- Severe malnutrition and intolerance to enteral nutrition

Some clinical studies suggest that parenteral nutrition is not always effective in the patient populations in which it is routinely used; thus, the decision to use it should be considered in light of the most recent research evidence.[1] In addition, parenteral nutrition is unlikely to be beneficial when used for periods of less than 7 to 14 days.[2]

Once the decision to use parenteral nutrition has been made, the access site must be selected. The access sites for intravenous feedings fall into two main categories: nutrients may be delivered into the **peripheral veins** located in the arms and legs or into the large-diameter **central veins** located near the heart.

Peripheral Parenteral Nutrition In **peripheral parenteral nutrition (PPN),** nutrient needs are met using only the peripheral veins. Peripheral veins can be damaged by overly concentrated solutions, however: phlebitis (inflammation of the vein) may result, characterized by redness, swelling, and tenderness at the infusion site. Therefore, the **osmolarity** of parenteral solutions is usually kept between 600 and 900 milliosmoles per liter,[3] so PPN can supply only limited amounts of energy and protein. The "How to" on p. 689 compares the expressions for *osmolarity* and *osmolality,* both of which can be used to express the osmolar concentration of a solution.

PPN is used most often in patients who require short-term nutrition support (about 7 to 10 days) and who do not have high nutrient needs or fluid restrictions. The use of PPN is not possible if the peripheral veins are too weak to tolerate the procedure. In most cases, it is necessary to rotate venous access sites to prevent inflammation.

Total Parenteral Nutrition Most patients meet their nutrient needs using the larger, central veins, where blood volume is greater and nutrient concentrations

HOW TO Express the Osmolar Concentration of a Solution

Chapter 12 described the concept of osmosis and explained how the solute concentration influences a solution's osmotic pressure. *Osmolarity* and *osmolality* are both used to express the osmolar concentration of a solution—that is, the concentration of osmotically active solutes in a solution:

- Osmolarity refers to the milliosmoles per liter of solution (mOsm/L).
- Osmolality refers to the milliosmoles per kilogram of solvent (mOsm/kg).

The *milliosmole* is a unit that represents the ions and molecules that contribute to the solution's osmotic pressure.

Whereas osmolarity refers to a volume of solution that includes the solutes of interest, osmolality refers to the solutes separately from the solvent in which they are dissolved. A second difference between the expressions is that osmolarity is expressed in terms of the solution's volume, whereas osmolality is expressed in terms of the solvent's weight.

Osmolarity and osmolality are both used in clinical practice, but they are derived in different ways. Osmolarity is typically calculated using equations that account for the nutrients and electrolytes in biological solutions. Osmolality is usually a measured value obtained using an *osmometer,* a common instrument in hospital laboratories.

Osmolarity and osmolality are roughly equivalent when describing dilute aqueous solutions at room or body temperature. This is because 1 liter of water weighs 1 kilogram, and the solutes contribute little to the volume of the solution.

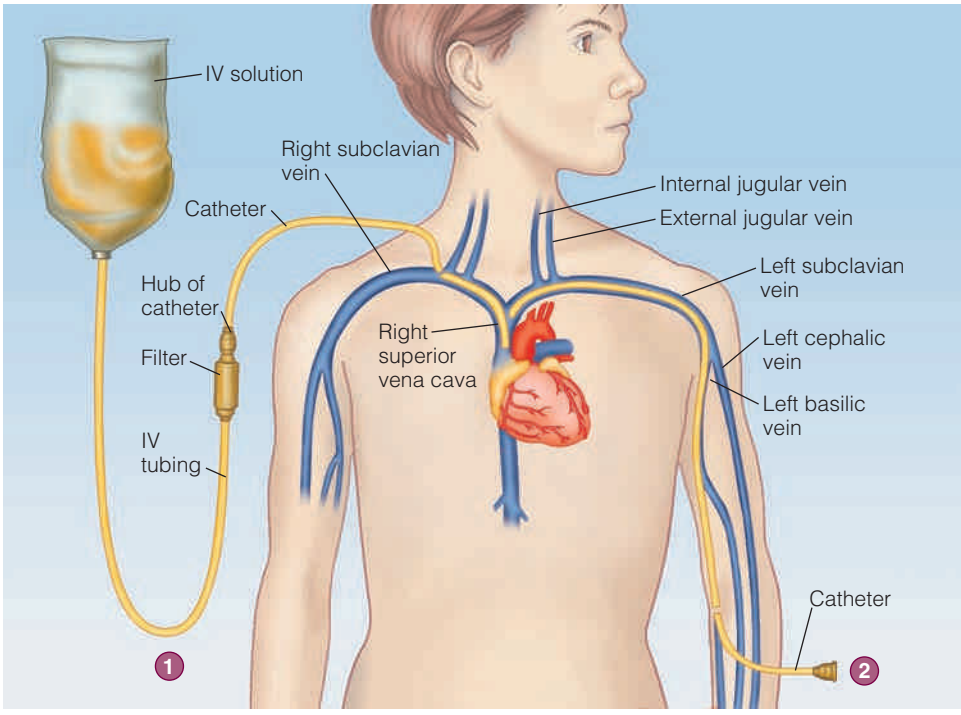
do not need to be limited. Because this method can reliably meet a person's complete nutrient requirements, it is called **total parenteral nutrition (TPN).** Central veins lie close to the heart, where the large volume of blood rapidly dilutes parenteral solutions. Therefore, patients with very high nutrient needs or fluid restrictions are able to receive the nutrient-dense solutions they require. TPN is also preferred for patients who require long-term intravenous feedings.

There are several ways to access central veins. The tip of a central venous **catheter** can be placed directly into a large-diameter central vein or threaded into a central vein through a peripheral vein (see Figure 21-2). Peripheral insertion of

total parenteral nutrition (TPN): a type of nutrition support in which intravenous feedings are delivered into a central vein.

catheter: a thin tube placed within a narrow lumen (such as a blood vessel) or body cavity; can be used to infuse or withdraw fluids or keep a passage open.

FIGURE 21-2 Accessing Central Veins for Total Parenteral Nutrition



1 Traditionally, central catheters enter the circulation at the right subclavian vein and are threaded into the superior vena cava with the tip of the catheter lying close to the heart. Sometimes catheters are threaded into the superior vena cava from the left subclavian vein, the internal jugular vein, or the external jugular vein.

2 Peripherally inserted central catheters usually enter the circulation at the basilic or cephalic vein and are guided up toward the heart so that the catheter tip rests in the superior vena cava.

central catheters is less invasive and lower in cost than the direct insertion of catheters into central veins; this method is usually preferred for short-term venous access (about two months or less in duration).[4]

IN SUMMARY

Parenteral nutrition support delivers nutrients intravenously. It is used in patients whose GI tract is not functioning and who may readily become malnourished. Patients receiving parenteral nutrition generally have intestinal disorders or are critically ill. If nutrients are infused directly into peripheral veins (peripheral parenteral nutrition), nutrient concentrations must be limited to avoid inflammation of the veins. The infusion of nutrients into central veins (total parenteral nutrition) can supply nutrient-dense solutions and is used for long-term intravenous feedings.

Parenteral Solutions

The pharmacies located within health care institutions are often responsible for preparing parenteral solutions. This arrangement is convenient because the pharmacist can customize formulations to meet patients' nutrient needs and because the solutions have a limited shelf life. This section describes the nutrients and characteristics of parenteral solutions.

Parenteral Nutrients

Parenteral solutions provide the combinations of amino acids, carbohydrate, lipids, vitamins, and minerals that are best suited to meet patients' requirements. Because the nutrients are provided intravenously, they must be given in forms that are safe to inject directly into the bloodstream.

Amino Acids Parenteral solutions contain all of the essential amino acids and various combinations of the nonessential amino acids. Amino acid concentrations range from 3.5 to 15 percent; ◆ the more concentrated solutions are used only for TPN. Just as in regular foods, the amino acids provide 4 kcalories per gram. Disease-specific amino acid solutions are available for patients with liver failure, kidney failure, and metabolic stress.

◆ A 10 percent amino acid solution supplies 10 g of amino acids per 100 mL of solution.

Carbohydrate Glucose is the main source of energy in parenteral feedings. It is provided in the form dextrose monohydrate, in which each glucose molecule is associated with a single water molecule. Dextrose monohydrate provides 3.4 kcalories per gram, slightly less than pure glucose, which provides 4 kcalories per gram. Dextrose solutions are available in concentrations between 2.5 and 70 percent. ◆ Concentrations greater than 12.5 percent are used only in TPN solutions.[5]

◆ A 10 percent dextrose solution provides 10 g of dextrose monohydrate per 100 mL of solution.

In parenteral solutions, the dextrose concentration is indicated by a "D" followed by its concentration in water (W) or normal saline (NS). For example, D5 or D5W indicates that a solution contains 5 percent dextrose in water. Similarly, D5/NS means that a solution contains 5 percent dextrose in normal saline.

Lipids Lipid emulsions supply essential fatty acids and are a significant source of energy. The emulsions usually contain triglycerides from soybean oil and safflower oil, phospholipids to serve as emulsifying agents, and glycerol to make the solutions isotonic. Lipid emulsions are available in 10, 20, and 30 percent solutions, containing 1.1, 2.0, and 3.0 kcalories per milliliter, respectively. Therefore, a 500-milliliter container of 10 percent lipid emulsion would provide 550 kcalories; the same volume of a 20 percent lipid emulsion would provide 1000 kcalories. ◆ In the United States, the 30 percent lipid emulsion can be used for preparing mixed parenteral solutions but cannot be directly infused into patients.[6]

◆ 500 mL of a 10% lipid emulsion:
500 mL × 1.1 kcal/mL = 550 kcal

500 mL of a 20% lipid emulsion:
500 mL × 2 kcal/mL = 1000 kcal

Lipid emulsions are often provided daily and may supply 20 to 30 percent of total kcalories. Including lipids as an energy source reduces the need for energy from dextrose and lowers the risk of hyperglycemia in glucose-intolerant patients. Lipid infusions must be restricted in patients with hypertriglyceridemia, however. There is also some concern that lipid emulsions that contain excessive linoleic acid can suppress some aspects of the immune response.

Fluids and Electrolytes Daily fluid needs are estimated to be about 30 to 40 milliliters per kilogram of body weight in young adults and 25 to 30 milliliters per kilogram of body weight in older adults, averaging between 1500 and 2500 milliliters for most people. The amounts are adjusted according to daily fluid losses and the results of hydration assessment.

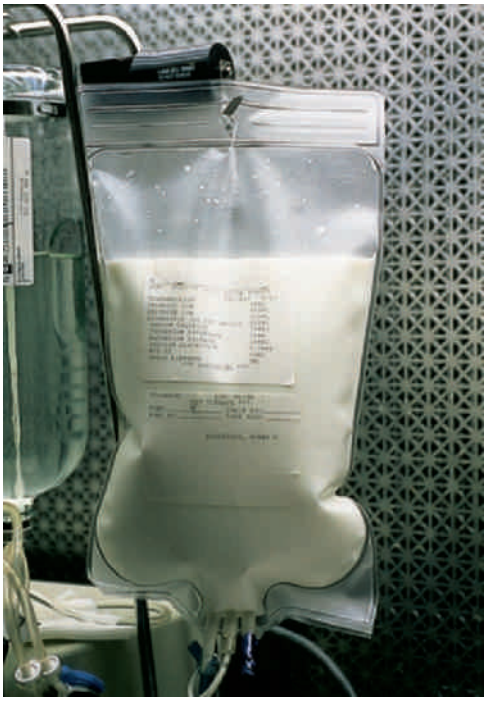
The electrolytes added to parenteral solutions include sodium, potassium, chloride, calcium, magnesium, and phosphorus. The amounts in parenteral solutions differ from DRI values because the nutrients are infused directly into the blood and are not influenced by absorption, as they are when consumed orally. Because electrolyte imbalances can be lethal, electrolyte management by experienced professionals is necessary whenever intravenous therapies are used. Blood tests are administered daily to monitor electrolyte levels until patients have stabilized.

The electrolyte content of parenteral solutions is expressed in *milliequivalents (mEq),* which are units indicating the number of ionic charges provided by electrolytes. ◆ The body's fluids are neutral solutions that contain equal numbers of positive and negative charges.

Vitamins and Trace Minerals Commercial multivitamin and trace mineral preparations are routinely added to parenteral solutions. All of the vitamins are usually included, although a preparation without vitamin K is available for patients using warfarin therapy.[7] ◆ The trace minerals usually added to parenteral solutions include zinc, copper, chromium, selenium, and manganese. Iron is excluded because it alters the stability of other ingredients in parenteral mixtures; therefore, special forms of iron need to be injected separately.

Osmolarity Recall that the osmolarity of PPN solutions is limited to 900 milliosmoles per liter because peripheral veins are sensitive to high nutrient concentrations, whereas TPN solutions may be as nutrient dense as necessary. The components of a solution that contribute most to its osmolarity are amino acids, dextrose, and electrolytes: as concentrations of these nutrients increase, the osmolarity of a solution increases. Because lipids contribute little to osmolarity, lipid emulsions are used to increase the energy provided in PPN solutions. Table 21-1 on p. 692 presents a method for estimating the osmolarity of a parenteral solution.

Medications To avoid the need for a separate infusion site, medications are occasionally added directly to parenteral solutions or infused through a separate port (attached via a Y-connector). The administration of a second solution using a separate port in a catheter is called a **piggyback.** Insulin, for example, is sometimes added by piggyback to improve glucose tolerance. Heparin (an anticoagulant) may be added to prevent clotting at the catheter tip. In practice, few medications are added to parenteral solutions so that potential drug-nutrient interactions can be avoided.



© Steve Gerard/Science Photo Library/Photo Researchers, Inc.

A lipid emulsion gives a parenteral solution a milky white color.

◆ Milliequivalents are determined by dividing an ion's molecular weight (MW) by its number of charges. For example:
- For calcium, MW = 40, and the ion has 2 positive charges: 40 ÷ 2 = 20. Thus, 1 mEq of Ca^{++} is equivalent to 20 mg of calcium.
- For sodium, MW = 23, and the ion has 1 positive charge: 23 ÷ 1 = 23. Thus, 1 mEq of Na^{+} is equivalent to 23 mg of sodium.
- *1 mEq of* Ca^{++} has the same number of charges as *1 mEq of* Na^{+}.

◆ Reminder: The anticoagulant warfarin works by interfering with vitamin K's blood-clotting function (see Chapter 19).

Solution Preparation

The parenteral solution prescribed depends on the patient's medical condition and nutrition status and the method of venous access. Prescriptions for parenteral solutions are highly individualized and may need to be recalculated daily until the patient's condition is stable. Figure 21-3 (p. 693) provides an example of a parenteral nutrition order form.

Parenteral Formulations When a parenteral solution contains dextrose, amino acids, and lipids, it is called a **total nutrient admixture (TNA),** a **3-in-1**

piggyback: the administration of a second solution using a separate port in an intravenous catheter.

total nutrient admixture (TNA): a parenteral solution that contains dextrose, amino acids, and lipids; also called a **3-in-1 solution** or an **all-in-one solution.**

TABLE 21-1 Osmolarity Contribution of Nutrients in Parenteral Solutions

For an estimate of the osmolarity of a 1-liter parenteral solution:

- Multiply the grams of amino acids in the solution by 10.
- Multiply the grams of dextrose in the solution by 5.
- Multiply the milliequivalents of electrolytes in the solution by 2.
- Multiply the grams of lipids in the solution by 1.5.

Add the values obtained to determine the approximate osmolarity.

Example:
A liter of a TPN solution has the approximate composition shown below. Calculate the osmolarity contribution of each component and estimate the total osmolarity of the solution.

Amino acids: 40 g	Sodium: 40 mEq	Calcium: 4.8 mEq
Dextrose: 250 g	Potassium: 35 mEq	Magnesium: 8 mEq
Lipids: 40 g	Chloride: 77 mEq	Phosphate: 21 mEq

Answer:
Amino acids: 40 g × 10 = 400 mOsm/L.
Dextrose: 250 g × 5 = 1250 mOsm/L.
Electrolytes: (40 + 35 + 77 + 4.8 + 8 + 21) × 2 = 371.6 mOsm/L.
Lipids: 40 g × 1.5 = 60 mOsm/L.
Total osmolarity: 400 + 1250 + 371.6 + 60 = 2081.6 mOsm/L.

NOTE: mEq = milliequivalents; mOsm/L = milliosmoles per liter.
SOURCE: Adapted from A. M. Coulston, C. L. Rock, and E. R. Monsen, eds., *Nutrition in the Prevention and Treatment of Disease* (San Diego: Academic Press, 2001), Table 7; p. 254.

solution, or an **all-in-one solution.** A **2-in-1 solution** excludes lipids, and the lipid emulsion is administered separately, often by piggyback administration. The administration of TNA solutions is simpler because only one infusion pump is required; however, the addition of lipid emulsion to solutions reduces their stability, a major concern when TNA solutions are compounded. Generally, a TNA with a high lipid concentration is more stable than one with a low lipid concentration, because diluting the lipids reduces the concentration of the phospholipids that emulsify the solution. Lipids are often administered separately when they are not a major energy source and are used only to provide essential fatty acids. The "How to" below describes a method for calculating the macronutrient and energy content of a parenteral solution.

2-in-1 solution: a parenteral solution that contains dextrose and amino acids, but excludes lipids.

nonprotein kcalorie-to-nitrogen ratio: a ratio between the nonprotein kcalories and nitrogen content of the diet; used to assess whether the nitrogen intake is sufficient for maintaining muscle tissue.

Nonprotein kCalorie-to-Nitrogen Ratio Some practitioners calculate the **nonprotein kcalorie-to-nitrogen ratio** to assess whether the nitrogen provided by the solution is sufficient for maintaining muscle tissue. A ratio of 150:1 to 200:1 is

HOW TO Calculate the Macronutrient and Energy Content of a Parenteral Solution

Suppose a patient is receiving 1.25 liters (1250 milliliters) of a parenteral solution that contains 5 percent amino acids and 30 percent dextrose, supplemented by 250 milliliters of a 20 percent lipid emulsion daily. How many grams of protein and carbohydrate is the person receiving, and what is the total energy intake for the day?

Amino acids:

$$5\%\ \text{amino acids} = \frac{5\ \text{g amino acids}}{100\ \text{mL}}$$

$$\frac{5\ \text{g amino acids}}{100\ \text{mL}} \times 1250\ \text{mL} = 62.5\ \text{g of amino acids}$$

$$62.5\ \text{g amino acids} \times 4.0\ \text{kcal/g} = 250\ \text{kcal}$$

Carbohydrate:

$$30\%\ \text{dextrose} = \frac{30\ \text{g dextrose}}{100\ \text{mL}}$$

$$\frac{30\ \text{g dextrose}}{100\ \text{mL}} \times 1250\ \text{mL} = 375\ \text{g of dextrose}$$

$$375\ \text{g dextrose} \times 3.4\ \text{kcal/g} = 1275\ \text{kcal}$$

Lipids:
Recall that a 20 percent lipid emulsion provides 2.0 kcalories per milliliter. If the patient is given 250 milliliters of the emulsion:

$$250\ \text{mL} \times 2.0\ \text{kcal/mL} = 500\ \text{kcal}$$

Total energy intake:

$$250\ \text{kcal} + 1275\ \text{kcal} + 500\ \text{kcal} = 2025\ \text{kcal}$$

SEND COMPLETED ORDERS TO PHARMACY

considered adequate for stable patients, whereas a ratio of 100:1 or less is preferred for critically ill patients who have difficulty maintaining muscle mass. The ratio is sometimes used as a guideline for preparing parenteral solutions, in conjunction with information related to the patient's clinical condition and nutrition status.[8] The "How to" on p. 694 shows how to calculate the nonprotein kcalorie-to-nitrogen ratio.

HOW TO Calculate the Nonprotein kCalorie-to-Nitrogen Ratio

The nonprotein kcalorie-to-nitrogen ratio of the diet is sometimes used to determine whether a patient is receiving adequate nitrogen to maintain muscle tissue. A ratio between 150:1 and 200:1 is often adequate for stable patients, whereas ratios of 100:1 and below may be necessary for patients who are critically ill.

To calculate the nonprotein kcalorie-to-nitrogen ratio, determine the energy intake from carbohydrates and lipids and compare this amount to the nitrogen intake. To determine the nitrogen intake, multiply the amino acid or protein intake by 16% (protein contains about 16% nitrogen by weight).

The "How to" on p. 692 describes a parenteral solution that provides 1275 kcalories from dextrose, 500 kcalories from lipids, and 62.5 grams of amino acids. Using these values to calculate the nonprotein kcalorie-to-nitrogen ratio:

Nonprotein kcalories:

1275 kcal (dextrose) + 500 kcal (lipids) = 1775 kcal

Nitrogen content:

62.5 g amino acids × 16% nitrogen = 62.5 g × 0.16 = 10 g

Nonprotein kcalorie-to-nitrogen ratio:

1775 ÷ 10 = 178:1

Thus, the parenteral solution in the example has a nonprotein kcalorie-to-nitrogen ratio of 178:1, which is likely to be adequate for a stable hospital patient.

Safety Concerns Intravenous feedings are similar to tube feedings in that careful attention to solution preparation and handling can minimize complications. To prevent bacterial contamination and maintain stability, parenteral solutions are compounded in the pharmacy under aseptic conditions, shielded from light, and refrigerated. Prior to infusion, the solutions are removed from the refrigerator and allowed to reach room temperature. During feedings, the solution and catheter need to be checked frequently for signs of contamination.

IN SUMMARY

Prescriptions for parenteral solutions are individualized to meet each patient's needs. The solutions are compounded in hospital pharmacies using commercial nutrient preparations and include amino acids, dextrose, electrolytes, vitamins, and trace minerals. Lipid emulsions may be included in the solution or may be administered separately. A parenteral solution that includes lipids is called a total nutrient admixture, a 3-in-1 solution, or an all-in-one solution. Few medications are added to parenteral solutions due to the potential for drug-nutrient interactions. Parenteral solutions are prepared and handled using aseptic techniques to prevent contamination.

Administering Parenteral Nutrition

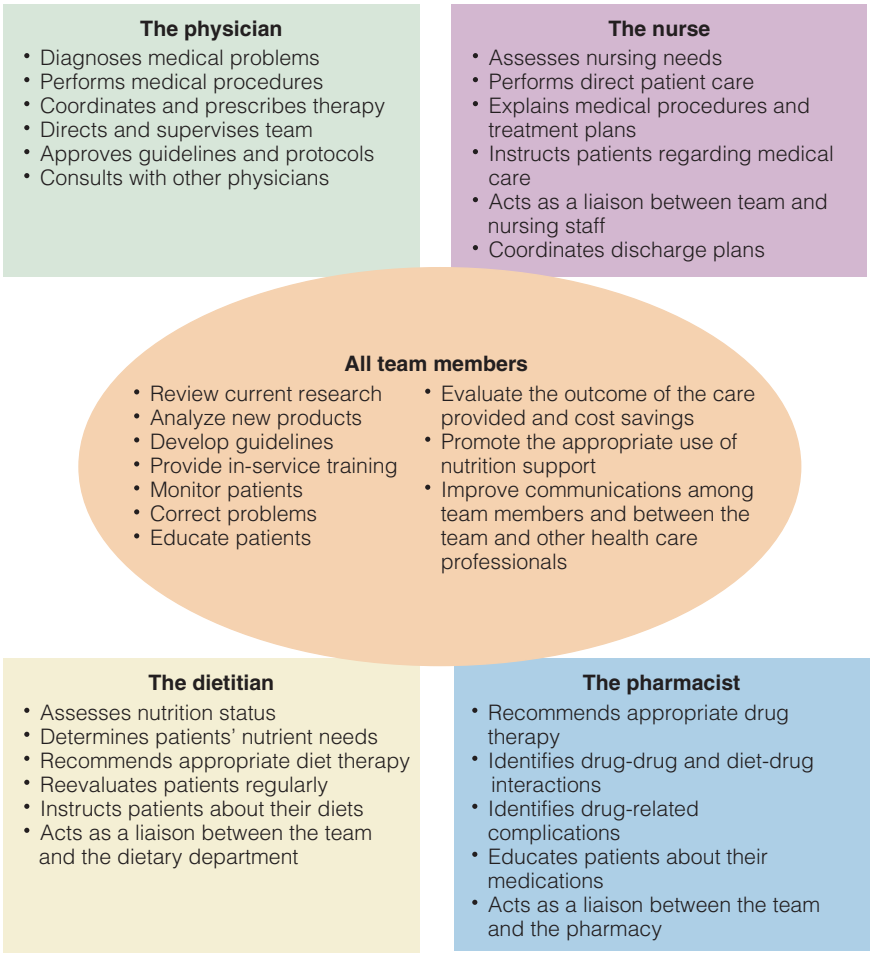
Parenteral nutrition is a complex treatment that requires skills from a variety of disciplines. Many hospitals organize nutrition support teams, ◆ consisting of physicians, nurses, dietitians, and pharmacists, that specialize in the provision of both intravenous and tube feedings. Members of the team may serve as advisers to other clinicians or may manage nutrition support directly. They may also have administrative responsibilities, such as receiving patients, purchasing supplies, developing guidelines, and keeping records. Figure 21-4 describes the typical roles of each member of the nutrition support team.

◆ Reminder: A *nutrition support team* is a multidisciplinary team of health care professionals who are responsible for the provision of nutrients by tube feeding or intravenous infusion.

Insertion and Care of Intravenous Catheters

Although skilled nurses can place catheters into peripheral veins, only qualified physicians can insert catheters directly into central veins. Patients may be awake for the procedure and be given local anesthesia. Unnecessary apprehension can be avoided by explaining the procedure to the patient beforehand.

FIGURE 21-4 The Nutrition Support Team



Catheter-related problems frequently cause complications (see Table 21-2). Catheters may be improperly positioned or may dislodge after placement. Air can leak into catheters, obstructing blood flow. Catheters in peripheral veins may cause phlebitis, necessitating reinsertion at an alternate site. A catheter may become clogged from blood clotting or from a buildup of scar tissue around the catheter tip. Catheters are also a leading cause of infection: contamination may be introduced during insertion or may develop at the placement site.

To reduce the risk of complications, nurses use aseptic techniques when inserting catheters, changing tubing, or changing a dressing that covers the catheter

TABLE 21-2 Potential Complications of Parenteral Nutrition

Catheter-Related	Metabolic
Air embolism	Abnormalities in liver function
Blood clotting at catheter tip	Electrolyte imbalances
Clogging of catheter	Gallbladder disease
Dislodgment of catheter	Hyperglycemia, hypoglycemia
Improper placement	Hypertriglyceridemia
Infection, sepsis	Metabolic bone disease
Phlebitis	Nutrient deficiencies
Tissue injury	Refeeding syndrome

TABLE 21-3 Patient Monitoring during Parenteral Nutrition

Before Starting

- Perform a nutrition assessment.
- Record body height, weight, and body mass index.
- Confirm catheter placement by X-ray.
- Check laboratory tests: blood glucose, sodium, potassium, calcium, phosphorus, magnesium, bicarbonate, serum proteins, liver enzymes, triglycerides, blood urea nitrogen, creatinine, bilirubin, complete blood count.

Every 4 to 8 Hours

- Check vital signs, including body temperature.
- Check blood glucose (once stabilized, check daily).
- Inspect catheter site for signs of inflammation or infection (frequency depends on patient condition).
- Check pump infusion rate and appearance of parenteral solution and tubing.

Daily

- Replace parenteral solution and tubing.
- Check blood glucose and serum electrolytes until stabilized.
- Monitor weight changes.
- Record fluid intake and output.

Several Times Weekly (or as needed)

- Reassess nutrition status.
- Check laboratory tests to monitor blood chemistry (once stabilized, may check less frequently).

site. Unusual bleeding or a wet dressing suggests a problem with catheter placement. A change in infusion rate may indicate a clogged catheter. Infection may be indicated by redness or swelling around the catheter site or by an unexplained fever. Routine inspections of equipment and frequent monitoring of patients' symptoms help to minimize the problems associated with catheter use.

Administration of Parenteral Solutions

Before determining the best method for administering the parenteral solution, the nutrition support team must consider the patient's clinical condition and the potential for complications.[9] The preferred protocols for initiating and advancing parenteral infusions vary among institutions. One approach is to start the infusion at a slow rate and increase the rate gradually over a 2- to 3-day period. For example, 40 milliliters per hour can be infused during the first 24 hours of administration (supplying 960 milliliters), and the rate can be increased by 1 liter per day until the goal rate is reached. Another method is to give the full volume of a nutrient-dilute solution on the first day and advance nutrient concentrations as tolerated. Some protocols suggest starting solutions at full strength unless there is a risk that the patient will become hyperglycemic. If complications are unlikely, the solution can usually be advanced to full volume and full strength by the second day of the infusion.[10]

Parenteral solutions can be infused continuously over 24 hours **(continuous parenteral nutrition)** or during 10- to 16-hour periods only **(cyclic parenteral nutrition).** Continuous feedings are given to critically ill and malnourished patients who cannot receive adequate nutrition in the shorter time periods. Cyclic feedings are often provided at night so that patients can participate in routine activities during the day. This method is especially suited to patients who require long-term parenteral support or who will be infusing parenteral solutions at home. Patients may begin with continuous feedings and transition to cyclic feedings as their condition improves.

Regular monitoring can help to prevent complications. The parenteral solution and tubing are checked daily for signs of contamination. Routine testing of glucose, lipids, and electrolyte levels helps to determine tolerance to solutions. Frequent reassessment of nutrition status may be necessary until a patient has stabilized. Rapid changes in infusion rate are discouraged in some patients due to a risk of developing hyperglycemia or hypoglycemia.[11] Table 21-3 lists some guidelines for monitoring patients undergoing intravenous feedings.

Discontinuing Intravenous Feedings

The method used for transitioning a patient to oral feedings depends on the patient's overall health and medical condition. The patient must have adequate GI function before parenteral feedings can be tapered off and enteral feedings begun. Other factors to consider include the length of time that the patient was receiving parenteral support, the type of intravenous feeding, and the follow-up treatment planned.

During the transition to oral feedings, a combination of feeding methods is often necessary. Parenteral feedings are usually tapered off at the same time that tube feedings or oral feedings are begun, such that the two feeding methods can together supply the needed nutrients. Clear liquids are generally the first foods offered and include pulp-free fruit juices, soft drinks, and clear broths; small amounts are given initially to determine tolerance. ◆ Later feedings include beverages and solid foods that are unlikely to cause discomfort. If gastrointestinal symptoms (such as nausea, vomiting, bloating, or diarrhea) develop, oral feedings are limited in size or frequency until the intestines adapt. Once about two-thirds to three-fourths of nutrient needs can be provided enterally, the intravenous feedings may be discontinued.

◆ Chapter 18 provides more information about the clear liquid diet.

continuous parenteral nutrition: continuous administration of parenteral solutions over a 24-hour period.

cyclic parenteral nutrition: administration of a parenteral solution over a 10- to 16-hour period.

Transitioning to an oral diet is sometimes difficult because a person's appetite remains suppressed for several weeks after parenteral nutrition is terminated. Patients receiving continuous parenteral feedings may have better appetites during the day if they are switched to nocturnal cyclic feedings before beginning oral intakes.

Managing Metabolic Complications

As has been discussed, the catheters used for parenteral nutrition may cause a number of serious complications. This section describes some metabolic complications that may result from parenteral feedings (review Table 21-2) and some suggestions for managing them.[12]

Hyperglycemia Hyperglycemia ◆ most often occurs in patients who are glucose intolerant or undergoing severe metabolic stress. It can be prevented by providing insulin along with feedings or by restricting the amount of dextrose in a solution. Dextrose infusions are generally limited to less than 5 milligrams per kilogram of body weight per minute in critically ill adult patients so that the carbohydrate intake does not exceed the maximum glucose oxidation rate. Premature infants are especially likely to develop hyperglycemia, because their pancreas and liver are not fully functioning.

◆ For most patients receiving parenteral nutrition, blood glucose levels should not exceed 200 mg/dL.

Hypoglycemia Although uncommon, hypoglycemia sometimes occurs when feedings are interrupted or discontinued or if excessive insulin is given. In patients at risk, such as young infants, feedings may be tapered off over several hours before discontinuation. Another option is to infuse a 10 percent dextrose solution at the same time that the parenteral feedings are interrupted or stopped.[13]

Hypertriglyceridemia Hypertriglyceridemia may develop in critically ill patients who cannot tolerate the amount of lipid emulsion supplied. Patients at risk include those with severe infection, liver disease, kidney failure, hyperglycemia, and use of immunosuppressant or corticosteroid medications. If blood triglyceride levels exceed 500 milligrams per deciliter, lipid infusions should be reduced or stopped.[14]

Refeeding Syndrome Severely malnourished patients who are fed aggressively (parenterally or otherwise) may develop **refeeding syndrome,** characterized by electrolyte and fluid imbalances and hyperglycemia. These effects occur because dextrose infusions raise circulating insulin levels, which promote anabolic processes that quickly remove phosphate, potassium, and magnesium from the blood. The altered electrolyte levels can lead to fluid retention and life-threatening changes in organ systems. Heart failure and respiratory failure are possible consequences.

Refeeding syndrome generally develops within two weeks of beginning parenteral feedings.[15] The patients at highest risk are those who have experienced chronic malnutrition or substantial weight loss. Symptoms include edema, cardiac arrhythmias, muscle weakness, and confusion. To prevent refeeding syndrome, health practitioners start parenteral feedings slowly and carefully monitor electrolyte and glucose levels when malnourished patients begin receiving nutrition support.

Abnormal Liver Function Fatty liver often results from parenteral support, but it is usually corrected when the parenteral feedings are discontinued. Long-term parenteral nutrition, however, may result in chronic, irreversible liver disease that can eventually lead to liver failure. The cause of the liver abnormalities is unclear.

Liver enzyme levels are monitored weekly during parenteral support, and abnormal values are often seen within weeks of beginning the feedings. The patients at highest risk are those with pre-existing GI or liver disorders, malnutrition, and severe infection.[16] To minimize the risk, practitioners are careful to avoid giving the patient excess energy, dextrose, or lipids. Some amount of enteral intake may be encouraged to reduce the amount of parenteral support necessary. Cyclic feedings may be less problematic than continuous feedings. Note that various critical illnesses and disease treatments can also cause liver complications, so parenteral nutrition cannot be assumed to be the underlying cause.[17]

refeeding syndrome: a condition that sometimes develops when a severely malnourished person is aggressively fed; characterized by electrolyte and fluid imbalances and hyperglycemia.

Gallbladder Disease Gallbladder problems frequently develop when the GI tract is not used for long periods. When parenteral nutrition continues for more than four weeks, sludge (thickened bile) often builds up in the gallbladder and may eventually lead to gallstone formation. Prevention is sometimes possible by initiating enteral feedings before problems develop. Patients requiring long-term parenteral nutrition may be given cholecystokinin injections to cause gallbladder contraction and bile release or may have their gallbladders removed surgically.

Metabolic Bone Disease Long-term parenteral nutrition has been associated with lower bone density and bone mineralization, which may be related to altered calcium, phosphorus, magnesium, and sodium metabolism. Imbalanced intakes of vitamin D, vitamin K, and phosphorus have also been implicated. Therefore, nutrition status and bone density are routinely monitored during long-term parenteral nutrition. The ideal intervention for metabolic bone disease varies among patients; it may include dietary adjustments, nutrient supplements, medications, and physical activity.[18]

IN SUMMARY

A nutrition support team, which is made up of physicians, nurses, dietitians, and pharmacists, may administer parenteral nutrition support or serve as advisers to other clinicians. Parenteral solutions may be initiated gradually or provided at full volume and full strength in selected patients. Critically ill patients may require continuous feedings, whereas healthier patients and long-term users may prefer cyclic feedings. Catheters are frequently the cause of complications, which include improper placement or dislodgment, infection, clotting, embolism, and phlebitis. Metabolic complications include hyperglycemia and hypoglycemia; hypertriglyceridemia; fluid and electrolyte imbalances; and diseases affecting the liver, gallbladder, and bone. When the need for parenteral nutrition resolves, patients are transitioned to an enteral diet as the volume of parenteral nutrition is gradually reduced. The Case Study can be used to check your understanding of the concepts introduced in this chapter.

Nutrition Support at Home

Occasionally, a patient must continue to receive nutrition support, either tube feedings or parenteral nutrition, after a medical condition has stabilized. For such a person, home nutrition support might be an option.

The use of home nutrition support is rapidly expanding. Current technology allows for the safe administration of nutrition support in home settings, and insurance coverage often pays a substantial portion of the costs. Home health services and home infusion pharmacies can provide the equipment, enteral formulas or parenteral solutions, and services necessary for home nutrition care. Most important, patients using these services can continue to receive specialized nutrition care while leading normal lives.

Candidates for Home Nutrition Support

Individuals referred for home nutrition support usually need long-term nutrition care for chronic medical conditions. Users of home nutrition services (or their families and other caregivers) must be intellectually capable of learning the necessary procedures, monitoring the treatment, and managing complications as necessary. The home should be clean and have adequate storage for formulas or solutions and

CASE STUDY Geologist Requiring Parenteral Nutrition

Jerry Huang, a 27-year-old geologist with an inflammatory intestinal disease, underwent a surgical procedure in which a substantial portion of his small intestine was removed. He had received TPN prior to surgery and continued to receive it afterwards. After 10 days, tube feeding was begun, which initially delivered very small feedings.

1. List some reasons why the nutrition support team initially chose TPN to provide nutrition support to this patient. How would you explain the need for parenteral feedings to Jerry?
2. Describe the components of a typical TPN solution. Calculate the energy content of 1 liter of a solution that provides 140 grams of dextrose monohydrate, 45 grams of amino acids, and 90 milliliters of 20 percent lipid emulsion. Then calculate the nonprotein kcalorie-to-nitrogen ratio in the solution. If Jerry's energy requirement is 2100 kcalories per day, how many liters of solution will he need each day?
3. Why is it important that Jerry begin enteral feedings as soon as possible? Assuming that Jerry eventually tolerates a tube feeding, in what ways can the health care team help Jerry make the transition from parenteral feedings to tube feedings? Consider some of the physiological problems that Jerry might face when he begins eating an oral diet.
4. If Jerry is unable to meet his nutrient needs orally, he may need to continue tube feeding or TPN at home. As you read through the section on nutrition support at home, consider the factors that would make Jerry a good candidate for a home nutrition support program. Consider both the benefits of a proposed program and the problems he could encounter.

equipment. The costs should be clearly explained to families who cannot get insurance reimbursement. Candidates for home nutrition support include the following:

- For home enteral nutrition, individuals who have functioning GI tracts and illnesses that prevent food from reaching the digestive tract. Examples include patients with head and neck cancers and individuals with neurological impairments that cause difficulties with swallowing.
- For home parenteral nutrition, individuals who have illnesses that severely impair nutrient absorption or cause motility problems in the stomach or intestines. Examples include persons who have had large portions of their small intestine removed and those with intestinal obstructions or malabsorption conditions.

Courtesy of Kendall Healthcare

Portable pumps and convenient carrying cases allow people who require nutrition support at home to move about freely.

Planning Home Nutrition Care

As with the nutrition support provided in health care facilities, planning for home nutrition care involves decisions about access sites, formulas, and nutrient delivery methods. Users of home services should be involved in the decision making to ensure long-term compliance and satisfaction.

Home Enteral Nutrition Access to the GI tract is possible using either nasal tubes or enterostomies. People sometimes learn to place nasogastric tubes themselves, which may improve acceptance of the therapy. Active children and adults often prefer low-profile gastrostomy tubes, which allow them to lead a more normal lifestyle. Jejunostomy tubes may be required for some individuals but are less convenient, because the frequent feedings required for people with jejunostomies can interfere with daytime activities.

The choice of formula for home use is influenced by its cost and availability. Insurance reimbursements do not always include the cost of formula, which is considered to be a "food" product. Fo r this reason, some people choose to prepare simple formulas at home. Blenderizing home-cooked foods is possible, but the foods need to be strained to remove particles and clumps that may obstruct the tube. Closed (ready-to-hang) feeding systems are useful for avoiding contamination risk

but are not appropriate for intermittent feedings that require smaller amounts of formula.

The advantages and disadvantages associated with the different administration methods should be fully discussed with patients. For gastric feedings, bolus infusions are simplest and can be quickly delivered. Gravity drip infusions eliminate the need for an infusion pump, but the delivery rates are less reliable. If intermittent feedings are appropriate, they should be tailored to daily routines. Portable pumps can free individuals from the need to infuse formula at home and can also be used when traveling.

Home Parenteral Nutrition Although both peripheral parenteral nutrition and total parenteral nutrition (TPN) can be provided at home, long-term therapy requires access to the larger, central veins that are appropriate for TPN. The catheter can be inserted so that the exit site is in a region that is accessible to the patient.

Parenteral solutions need to be sterile and aseptically prepared, and people who mix their own solutions must be carefully trained. Ready-made parenteral solutions require refrigeration and are stable for limited periods; for example, TNA (total nutrient admixture) solutions may be stable for only one week when refrigerated.

Most people prefer cyclic infusions over continuous infusions and transition to cyclic infusions before discharge from the hospital. Because an infusion pump is required for home TPN, sufficient battery backup should be on hand in case electrical service is interrupted. Portable pumps are helpful for individuals who lead an active lifestyle or prefer to infuse during the day.

Quality-of-Life Issues

Although home nutrition programs can help to improve health and extend life, consumers of home services and their families may struggle with the lifestyle adjustments required. In addition to the economic impact of nutrition support, home feedings are often time-consuming and inconvenient. Activities and work schedules must be planned around feedings. Extra planning is needed and precautions must be taken when a person wants to travel or participate in sports activities. Explaining one's medical needs to friends and acquaintances may be embarrassing.

Among physical difficulties, people receiving nocturnal feedings often cite disturbed sleep as a major problem. Disruptions may be due to multiple nighttime bathroom visits, noisy infusion pumps, or difficulty finding a comfortable sleeping position when "hooked up." People using parenteral support sometimes prefer infusing solutions during the day to improve their sleeping patterns.

Among social issues, the inability to consume meals with family and friends is often a great concern. Some individuals may be able to eat small amounts of food or may decide to sit at the table to participate in the conversation. Joining friends at restaurants and attending certain types of social events, however, can be problematic.

People who depend on nutrition support face a number of stressful issues that can affect quality of life. Although parenteral and enteral nutrition are life-sustaining therapies, both are associated with serious complications. Many people find that their lifestyles need to be greatly altered to accommodate nutrition therapy and may experience fear, anxiety, and depression. Support groups or counseling resources may help patients cope with ongoing stresses. ◆

◆ The Oley Foundation is an excellent source of outreach services, emotional support, and current information for people who require home nutrition support (**www.oley.org**).

IN SUMMARY

Candidates for home enteral nutrition services have functional GI tracts but are unable to consume food orally. Candidates for home parenteral nutrition have illnesses that impair nutrient absorption or cause motility problems. Patients and caregivers should participate in decisions about access sites, formulas, and nutrient delivery methods. Enteral formulas and parenteral solutions can be prepared in the home. The use of portable pumps may help individuals lead a normal lifestyle. Nevertheless, lifestyle adjustments to nutrition support may be difficult and stressful.

Clinical Portfolio

CENGAGENOW™
academic.cengage.com/login

- A liter of a TPN solution contains 500 milliliters of 50 percent dextrose solution and 500 milliliters of 5 percent amino acid solution. Determine the daily energy and protein intakes of a person who receives 2 liters of such a solution. Calculate the average daily energy intake if the person also receives 500 milliliters of a 20 percent fat emulsion 3 times a week.
- Consider the social, psychological, clinical, and financial ramifications of using home parenteral nutrition, with no foods allowed by mouth, in answering the following questions:

  a. What would be the advantages of living at home instead of in a hospital or other residential facility? Can you think of some disadvantages?
  b. Think about how you, as the patient, might manage daily feedings: consider the time, cost, and commitment required to maintain the therapy.
  c. If not allowed to consume foods, what possible difficulties might you encounter? How would you handle holidays and special occasions that center around food?

NUTRITION ASSESSMENT CHECKLIST for People Receiving Parenteral Nutrition

Medical History

Check the medical record for medical conditions that:

- Prevent the use of enteral nutrition
- Indicate the appropriate feeding route (peripheral versus central)
- Suggest the length of time that parenteral nutrition will be required

Monitor the medical record for complications or risks that may influence the parenteral solution formulation or delivery technique, including:

- Acid-base imbalances
- Fluid and electrolyte imbalances
- Hyperglycemia or hypoglycemia
- Hypertriglyceridemia
- Pre-existing GI or liver disease
- Refeeding syndrome

Medications

For medications added to the parenteral solution, determine the:

- Medication's compatibility with the parenteral solution
- Length of time that the medication can remain stable in solution

For medications infused separately, determine:

- Length of time that the feeding may need to be stopped
- Adjustments in solution infusion to compensate for the medication delivery

Dietary Intake

To assess nutritional adequacy, check to see whether:

- Patient's nutrient needs were correctly determined
- Solution is administered as prescribed
- Infusion pump is operating correctly

Anthropometric Data

Measure baseline height and weight, and monitor daily weights. If weight is not appropriate:

- Determine whether energy needs have been correctly assessed.
- Check to see if the parenteral solution is being delivered as prescribed.
- Check for signs of dehydration or overhydration.

Laboratory Tests

Check serum and urine tests for signs of:

- Fluid, electrolyte, and acid-base imbalances
- Hyperglycemia or hypoglycemia
- Hypertriglyceridemia
- Abnormal liver function
- Adequacy of protein intake (serum protein levels)
- Improvement or deterioration of medical condition

Physical Signs

Routinely monitor the following:

- Catheter insertion site for signs of infection or inflammation
- Blood pressure, temperature, pulse, and respiration for signs of fluid, electrolyte, and acid-base imbalances

Look for physical signs of:

- Dehydration or overhydration
- Protein-energy malnutrition
- Malnutrition

STUDY QUESTIONS

CENGAGENOW™

To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Identify the individuals who are most likely to benefit from parenteral nutrition support. (pp. 687–688)
2. Compare the general characteristics of peripheral parenteral nutrition (PPN) and total parenteral nutrition (TPN). Discuss the advantages and disadvantages of each of these methods. (pp. 688–690)
3. Describe how amino acids, carbohydrate, and lipids are provided in parenteral solutions. List the vitamins and minerals that are usually included. (pp. 690–691)
4. Identify the components of parenteral solutions that contribute to osmolarity. Explain how the osmolarity of a solution can be estimated. (pp. 691–692)
5. Compare the components of total nutrient admixtures (TNA) and 2-in-1 solutions. Describe the advantages and disadvantages associated with the use of TNA solutions. (pp. 691–692)
6. Compare the different methods for administering parenteral solutions. List the parameters that are typically monitored during parenteral feedings. (p. 696)
7. Explain how patients make the transition from parenteral to oral feedings. (pp. 696–697)
8. Discuss the potential complications associated with parenteral nutrition. Suggest ways in which these complications can be prevented or corrected. (pp. 697–698)
9. Discuss how home nutrition support is administered. Identify ideal candidates for these services and the problems that patients may experience. (pp. 698–700)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 703.

1. TPN is preferred over PPN for a patient who:
   a. does not have high nutrient requirements.
   b. needs long-term parenteral nutrition support.
   c. has strong peripheral veins and moderate nutrient needs.
   d. needs parenteral feedings as a supplement to tube feedings.
2. Which of the following cannot be delivered intravenously?
   a. dextrose
   b. amino acids
   c. lipid emulsions
   d. hydrolyzed enteral formulas

3. How many kcalories are supplied by 500 milliliters of an 8.5 percent amino acid solution?
   a. 60
   b. 170
   c. 340
   d. 500
4. For a patient receiving central TPN who also receives intravenous lipid emulsions two or three times a week, the lipid emulsions serve primarily as a source of:
   a. essential fatty acids.
   b. cholesterol.
   c. fat-soluble vitamins.
   d. concentrated energy.
5. Which nutrient is often omitted from parenteral solutions because it may destabilize other ingredients in the solution?
   a. calcium
   b. vitamin K
   c. iron
   d. chromium
6. Complications associated with parenteral feedings may include:
   a. hyperglycemia.
   b. hypertriglyceridemia.
   c. infection.
   d. all of the above.
7. Routine monitoring of patients on TPN requires all of the following *except:*
   a. serum electrolyte measurement.
   b. monitoring for daily weight changes.
   c. indirect calorimetry.
   d. liver enzyme tests.
8. The transition from parenteral feedings to an oral diet is primarily designed to:
   a. improve appetite.
   b. prevent hypoglycemia.
   c. prevent apprehension about eating.
   d. ensure that nutrient needs will continue to be met.
9. Refeeding syndrome causes dangerous fluctuations in:
   a. electrolytes.
   b. liver enzymes.
   c. triglycerides.
   d. ketone bodies.
10. Patients using home parenteral nutrition:
   a. are unable to use TNA solutions.
   b. are usually given continuous rather than cyclic infusions.
   c. require infusion pumps for use at home.
   d. are generally unable to work out of the home or travel.

Ethical Issues in Nutrition Care

© Carolyn A. McKeone/Photo Researchers, Inc.

As with other medical technologies, the availability of specialized nutrition support forces health care professionals and members of our society to face difficult **ethical** issues. When medical treatments prolong life by merely delaying death, the lifetime that remains may be of extremely low quality. This highlight examines the ethical dilemmas that clinicians must face when dealing with patients in critical care. The glossary below defines the relevant terms.

Ethical Considerations

If providing nutrition care can do little to promote recovery, is it morally and legally appropriate to withhold or to withdraw nutrition support? Do patients and family members have the rights to make these types of decisions themselves? How important is the input of the health professional? In attempting to answer questions such as these, health professionals must consider the following ethical principles:[1]

- A patient has the right to make decisions concerning his or her own well-being **(patient autonomy),** even if refusing treatment could result in death. It is generally accepted that a patient's preferences should take precedence over the desires of others.[2]
- A patient should be fully informed of a treatment's benefits and risks in a fair and honest manner **(disclosure).** A patient's acceptance of a treatment that has been adequately disclosed is considered **informed consent.**
- A patient must have the mental capacity to make appropriate health care decisions **(decision-making capacity).** If a patient is mentally incapable of doing so, a person designated by the patient should serve as a **surrogate** decision maker.

GLOSSARY

advance directive: written or oral instruction regarding one's preferences for medical treatment to be used in the event of becoming incapacitated.

beneficence (be-NEF-eh-sense): the act of performing beneficial services rather than harmful ones.

cardiopulmonary resuscitation (CPR): life-sustaining treatment that supplies oxygen and restores a person's ability to breathe and pump blood.

decision-making capacity: the ability to understand pertinent information and make appropriate decisions; known as *decision-making competency* within the legal system.

defibrillation: life-sustaining treatment in which an electronic device is used to shock the heart and reestablish a pattern of normal contractions. Defibrillation is used when the heart has arrhythmias or has experienced cardiac arrest.

dialysis: life-sustaining treatment in which a patient's blood is filtered using selective diffusion through a semipermeable membrane; substitutes for kidney function.

disclosure: the act of revealing pertinent information. For example, clinicians should accurately describe proposed tests and procedures, their benefits and risks, and alternative approaches.

distributive justice: the equitable distribution of resources.

do-not-resuscitate (DNR) order: a request by a patient or surrogate to withhold cardiopulmonary resuscitation.

durable power of attorney: a legal document (sometimes called a *health care proxy*) that gives legal authority to another (a *health care agent*) to make medical decisions in the event of incapacitation.

ethical: in accordance with accepted principles of right and wrong.

futile: medical care that will not improve the medical circumstances of a patient.

health care agent: a person given legal authority to make medical decisions for another in the event of incapacitation.

informed consent: a patient's or caregiver's agreement to undergo a treatment that has been adequately disclosed. Persons must be mentally competent in order to make the decision.

living will: a written statement that specifies the medical procedures desired or not desired in the event that a person is unable to communicate or is incapacitated; also called a *medical directive.*

maleficence (mah-LEF-eh-sense): the act of doing evil or harm.

mechanical ventilation: life-sustaining treatment in which a mechanical ventilator is used to substitute for a patient's failing lungs.

patient autonomy: a principle of self-determination, such that patients (or surrogate decision makers) are free to choose the medical interventions that are acceptable to them, even if they choose to refuse interventions that may extend their lives.

persistent vegetative state (PVS): a vegetative mental state resulting from brain injury that persists for at least one month. Individuals lose awareness and the ability to think but retain noncognitive brain functions, such as motor reflexes and normal sleep patterns.

surrogate: a substitute; a person who takes the place of another.

- The potential benefits **(beneficence)** of any treatment should outweigh its potential harm **(maleficence).**
- Health care providers must determine whether the provision of health care to one patient would unfairly limit the care of other patients **(distributive justice).**

Although these principles may seem simple and obvious, it is often difficult to determine the appropriate action to take during intensive care.[3] When clinicians and families disagree, the courts may be asked to decide.

When a patient's preferences are unknown, the medical staff is obligated to provide any and all available care that is likely to sustain the patient's life. Nutrition support and hydration are both considered life-sustaining treatments because withholding or withdrawing either can result in death. Other life-sustaining treatments include **cardiopulmonary resuscitation (CPR),** which supplies oxygen and restores a person's ability to breathe and pump blood; **defibrillation,** in which an electronic device shocks the heart and reestablishes normal contractions; **mechanical ventilation,** which substitutes for lung function; and **dialysis,** which substitutes for kidney function.

Ethical Dilemmas

Although life-sustaining treatments are readily provided to patients who have a reasonable chance of recovering from illness, it is sometimes difficult to determine the best course of action for patients who are dying or who are unlikely to regain consciousness. Under such circumstances, such treatments may be considered **futile** because they are unable to improve the outcome of disease or increase the patient's comfort and well-being. If patients or caregivers demand treatment that health practitioners have determined to be useless, a legal resolution may be required. Conversely, medical personnel may find it objectionable to withdraw life support when they know that the inevitable consequence will be the patient's death.

Legal Decisions

One of the landmark cases involving nutrition support concerned Nancy Cruzan, who suffered permanent and irreversible brain damage after a car crash in 1983, when she was 26 years of age.[4] After she had been in a **persistent vegetative state (PVS)** for five years, her parents requested permission to discontinue tube feeding, but hospital staff refused to honor the request, and the matter was taken to court. The Missouri Supreme Court determined that Nancy had never definitively stated her "right to die" wishes and that her parents were unable to make such a request for her. The court also stated that preserving life, no matter what its quality, should take precedence over all other considerations. Nancy's parents appealed the ruling, but in 1990, the U.S. Supreme Court upheld the Missouri Supreme Court in a five-to-four decision. Three witnesses were eventually found who could testify that Nancy would not desire life-sustaining treatment under the circumstances, and the court finally granted permission to remove the feeding tube. This case illustrates the importance of having an **advance directive** (discussed in a later section) that clearly indicates one's preferences for medical treatment in the event of incapacitation.

In a more recent case that received widespread media attention, the spouse and parents of a patient in a persistent vegetative state fought a ten-year legal battle over her medical care. In 1990, at the age of 25, Terri Schiavo suffered a full cardiac arrest.[5] She initially fell into a coma, but her condition evolved into a persistent vegetative state that was considered irreversible. Despite the neurologists' diagnosis and a series of computed tomography (CT) and magnetic resonance imaging (MRI) scans showing extensive brain atrophy, her parents maintained that she was minimally conscious and could improve with rigorous treatment. Her husband, who was legally responsible for her care, insisted that she would never have wanted to be kept alive in a vegetative state. Like Nancy Cruzan, Terri had never expressed her wishes in an advance directive.

In 1998, Terri's husband filed a petition to have her feeding tube removed, and a Florida court approved the motion in February 2000. Although Terri's parents appealed, an appeals court affirmed the decision, and the Florida Supreme Court declined to review the case. In April 2001, Terri's physicians removed her feeding tube, but within days, a federal circuit court judge ordered it to be reinserted and reopened the case. Eventually, the motions filed by the parents were dismissed, and Terri's feeding tube was removed for the second time in October 2003. Within days, the Florida legislature passed a bill known as "Terri's Law" that gave the governor the authority to intervene, and Governor Jeb Bush ordered the feeding tube reinserted**.** A year later, Florida's Supreme Court declared Terri's Law to be unconstitutional. Although the governor appealed the decision, his appeal was rejected in January 2005. Terri's feeding tube was removed for the third time in March 2005. Despite emergency petitions by her parents and an attempt by the U.S. Congress to have her case reconsidered, the courts refused to grant a restraining order, and Terri died 13 days after her feeding tube was removed.

Religious Viewpoints

The withdrawal of nutrition support and other life-sustaining treatments may not be acceptable to persons of some religious faiths. For example, Orthodox Jews believe that the soul is present in people who are alive (even if permanently unconscious) and disallow any actions that would hasten death.[6] If a person's or family's religious beliefs are not in accord with medical recommendations, health practitioners are expected to consider the viewpoint and try to resolve the issue in some way. If practitioners are unable to comply with the wishes of a patient or caregiver, the care of the patient should be transferred elsewhere.

Advance Planning

Health care professionals should discuss the importance of advance directives with competent patients. Individuals are encouraged to discuss their medical preferences with family members and surrogate decision makers so that their wishes will be considered in the

event that they become incapacitated. Advance directives are incorporated into the medical record and updated when appropriate. They take effect only if a physician determines that a patient lacks the ability to understand and make decisions about available treatments. If a person's preferences are unknown, decisions are based on a patient's best interests as determined by a caregiver or family member.[7]

Advance Directives

A person may declare preferences about medical treatments in a **living will,** sometimes called a *medical directive.* Living wills can include detailed instructions about life-sustaining procedures that a person does or does not want. Another important directive is a **durable power of attorney** (sometimes called a *health care proxy*), in which another person (a **health care agent**) is appointed to act as decision maker in the event of incapacitation. The agent should understand one's medical preferences and be absolutely trustworthy. Only one person can be designated, although one or two alternates may also be listed. If an agent is given comprehensive power to supervise care, he or she may make decisions about medical staff, health care facilities, and medical procedures.

Laws regarding advance directives vary from state to state. In some states, nutrition and hydration are not considered life-sustaining treatments, and a person's instructions about them may need to be indicated separately. Some states restrict the use of advance directives to terminal illness or disallow them if a woman is pregnant. State statutes also specify characteristics of people who may serve as health care agents and witnesses. Generally, advance directives created in one state are honored in another.

The Do-Not-Resuscitate Order

A **do-not-resuscitate (DNR) order** is frequently used to withhold CPR in the event of cardiopulmonary arrest, which occurs too suddenly for deliberate decision-making.[8] A DNR order is written in the medical record as other directives are, but it does not exclude the use of other life-prolonging measures. A DNR order is most often used in patients with serious illnesses or advanced age. Some institutions allow a physician to write a DNR order for a patient who has a poor prognosis, but the physician must inform the patient or surrogate if this is done.

Organ and Tissue Donation

End-of-life decisions invariably raise questions about a dying patient's preferences concerning organ and tissue donation. Even if a donor card has been signed, it is important to let family members know one's wishes, as the family may need to sign a consent form in order for donation to occur. Although organ donation is a difficult topic to bring up near the time of death, potential donors can be assured that their gift could greatly enhance or save the lives of others.

Ethical questions sometimes arise when organs are donated. A physician must alert an organ procurement team about a donor's existence and arrange to maintain organ functions until organs are retrieved. Treatments that maintain the viability of organs and tissues cannot be used if they may harm the donor. Sometimes the care of a donor and the needs of a potential recipient may appear to be in conflict, but the care of donors and recipients is always kept separate and performed by different physicians.

Ongoing Issues

Despite the availability of advance directives, only about 20 percent of people in the United States have completed one.[9] Furthermore, advance directives are often unavailable when intensive care decisions are made: one study found that only 57.5 percent of patient charts indicating the existence of an advance directive actually contained a copy.[10] In addition, advance directives are sometimes too general or vague to guide treatment decisions.

Physicians must often make treatment decisions before they have a chance to discuss them with patients or caregivers.[11] In many cases, life-sustaining treatments are begun without the prior knowledge of patients or their decision makers, or treatments continue even if patients want them stopped. Patients who are fully aware of treatment options and clearly state their preferences are more likely to be successful at obtaining the care they desire.

Medical decisions that are planned in advance and discussed with close friends and family can help to prevent decision-making dilemmas during emergency situations. Health practitioners should strive to provide the best information possible so that patients can consider all of the medical options available and make their preferences known to medical personnel.

Nutrition in the Clinical Setting

The body's dramatic response to severe stress can alter metabolism enough to threaten survival. Many patients with severe stress require life support measures and intensive monitoring. Stress also raises nutritional needs considerably—increasing the risk of malnutrition even in previously healthy individuals. Providing nutrition care for these patients is not only challenging; it is often ineffective for preventing weight loss and muscle tissue losses. Despite these difficulties, the health care professional must determine the best measures to take in order to limit damage and promote recovery.

CHAPTER 22

Metabolic and Respiratory Stress

CHAPTER OUTLINE

The Body's Responses to Stress and Injury • Hormonal Responses to Stress • The Inflammatory Response

Nutrition Treatment of Acute Stress • Determining Nutritional Requirements • Approaches to Nutrition Care in Acute Stress • Patients with Burn Injuries

Nutrition and Respiratory Stress • Chronic Obstructive Pulmonary Disease • Respiratory Failure

HIGHLIGHT 22 Multiple Organ Dysfunction Syndrome

This chapter addresses the nutrition care provided to patients who undergo certain types of physiological stress. **Metabolic stress,** a disruption in the body's internal chemical environment, can result from uncontrolled infections or extensive tissue damage, such as deep, penetrating wounds or multiple broken bones. As the first part of this chapter explains, the body's stress response is an attempt to restore balance, but it can have both helpful and harmful effects. Later sections of this chapter describe **respiratory stress,** which is characterized by inadequate oxygen and excessive carbon dioxide in the blood and tissues. Both metabolic and respiratory stress can lead to **hypermetabolism** (above-normal metabolic rate), **wasting** (breakdown of muscle mass and loss of strength), and in severe circumstances, life-threatening complications. The highlight following this chapter discusses the causes and consequences of **multiple organ dysfunction syndrome,** the simultaneous dysfunction of two or more organ systems, which is often fatal.

The Body's Responses to Stress and Injury

The **stress response** is the body's *nonspecific* response to a variety of stressors, such as infection, fractures, surgery, and burns. During stress, the body's metabolic processes focus on immediate survival, while functions of lesser consequence are delayed. Energy is of primary importance, and therefore the energy nutrients are mobilized from storage and made available in the blood. Heart rate and respiration (breathing rate) increase to deliver oxygen and nutrients to cells more quickly, and blood pressure rises. Meanwhile, energy is diverted from processes that are not life sustaining, such as growth, reproduction, and long-term immunity. If

metabolic stress: a disruption in the body's chemical environment due to the effects of disease or injury. Metabolic stress is characterized by changes in metabolic rate, heart rate, blood pressure, hormonal status, and nutrient metabolism.

respiratory stress: abnormal gas exchange between the air and blood, resulting in lower-than-normal oxygen levels and higher-than-normal carbon dioxide levels.

hypermetabolism: a higher-than-normal metabolic rate.

wasting: the breakdown of muscle tissue that results from disease or malnutrition.

multiple organ dysfunction syndrome: the dysfunction of two or more organ systems that develops during intensive care; often results in death.

stress response: the chemical and physical changes that occur within the body during stress.

© Bruce Ayres/Getty Images

Although severe metabolic stress can have damaging consequences, the healthy body handles minor stresses quickly and efficiently.

◆ The catecholamines, glucagon, and cortisol have actions that oppose those of insulin and are therefore referred to as *counterregulatory hormones*.

stress continues for a long period, interference with these processes begins to cause damage, possibly resulting in growth retardation and illness.

Hormonal Responses to Stress

The stress response is mediated by several hormones, which are released into the blood soon after the onset of injury (see Table 22-1).[1] The catecholamines (epinephrine and norepinephrine), often called the *fight-or-flight hormones,* stimulate heart muscle, raise blood pressure, and increase metabolic rate. Epinephrine also promotes glucagon secretion by the pancreas, prompting the release of nutrients from storage. The steroid hormone cortisol enhances protein degradation, raising amino acid levels in the blood and making amino acids available for conversion to glucose. All of these hormones have similar effects on glucose and fat metabolism, causing the breakdown of glycogen (glycogenolysis), the production of glucose from amino acids (gluconeogenesis), and the breakdown of triglycerides in adipose tissue (lipolysis). ◆ Thus, the combined effects of these hormones contribute to hyperglycemia, which often accompanies critical illness. Two other hormones induced by stress, aldosterone and antidiuretic hormone, help to maintain blood volume by stimulating the kidneys to reabsorb more sodium and water, respectively.

Cortisol's effects can be detrimental when stress is prolonged. In excess, cortisol causes the depletion of protein in muscle, bone, connective tissue, and skin. It impairs wound healing, so high cortisol levels are especially dangerous for a patient with severe injuries. Because cortisol inhibits protein synthesis, consuming more protein cannot easily reverse tissue losses. Excess cortisol also leads to insulin resistance, contributing to hyperglycemia. In addition, cortisol suppresses immune responses, increasing susceptibility to infection. Note that the pharmaceutical forms of cortisol are common anti-inflammatory medications (such as *cortisone* and *prednisone*); their long-term use can cause undesirable side effects such as muscle wasting, thinning of the skin, diabetes, and early osteoporosis.

The Inflammatory Response

Cells of the immune system mount a quick, nonspecific response to infection or tissue injury. This so-called **inflammatory response** serves to contain and destroy infectious agents (and their products) and prevent further tissue damage. The inflammatory response also triggers various events that promote healing. As in the stress response, however, there is a delicate balance between a response that protects tissues from further injury and an excessive response that can cause additional damage to tissue.

TABLE 22-1 Metabolic Effects of Hormones Released during the Stress Response

Hormone	Metabolic Effects
Catecholamines	• Increase in metabolic rate • Glycogen breakdown in liver and muscle • Glucose production from amino acids • Release of fatty acids from adipose tissue • Glucagon secretion from pancreas
Glucagon	• Glycogen breakdown in liver • Glucose production from amino acids • Release of fatty acids from adipose tissue
Cortisol	• Protein degradation • Enhancement of glucagon's action on liver glycogen • Glucose production from amino acids • Release of fatty acids from adipose tissue
Aldosterone	• Retention of sodium
Antidiuretic hormone	• Retention of water

inflammatory response: a group of nonspecific immune responses to infection or injury.

The Inflammatory Process The inflammatory response begins with the dilation of blood vessels that deliver blood to the site of an injury (arterioles) and the constriction of small blood vessels that carry blood away from an infected area (venules). The capillaries within the damaged tissue become more permeable, allowing some blood plasma to escape and causing local edema. These changes in blood vessels ◆ limit or prevent the spread of infection and encourage the entry of immune cells that can destroy foreign agents (see Figure 22-1). Among the first cells to arrive are the **phagocytes,** which slip through gaps between the endothelial cells that form the vessel walls. The phagocytes engulf microorganisms and destroy them with hydrolytic enzymes and reactive forms of oxygen. When inflammation becomes chronic, these normally useful products of phagocytes can damage healthy tissue.

◆ The classic signs of inflammation that accompany altered blood flow are:
- *Swelling*—from the accumulation of fluid at the site of injury
- *Redness*—from the dilation of small blood vessels in the injured area
- *Heat*—from the influx of warm arterial blood
- *Pain*—from the pressure of edema within the damaged tissue and the actions of certain chemical mediators on pain receptors

Mediators of Inflammation Numerous chemical substances control the inflammatory process. These *mediators* are released from damaged tissue, blood vessel cells, and activated immune cells. Many of them help to regulate more than one step in the process. Some of the examples that follow were introduced in Highlight 17's discussion of immunity. Histamine, a small molecule similar to an amino acid in structure, is released from granules within **mast cells,** causing vasodilation and capillary permeability. ◆ Fragments of complement proteins ◆ trigger histamine's release from mast cells and help to recruit and activate phagocytes. Other compounds that participate in the inflammatory process include several cytokines ◆ (especially interleukin-1, interleukin-6, and tumor necrosis factor-α) and various **eicosanoids** (which are derived from dietary fatty acids). Note that most anti-inflammatory medications, including steroidal drugs (such as cortisone and prednisone) and nonsteroidal anti-inflammatory drugs (such as aspirin and ibuprofen), act by blocking eicosanoid synthesis.

◆ *Antihistamines* are medications taken to reduce the effects of histamine.

◆ Reminder: *Complement* is a collective term for a group of plasma proteins that assist the activities of antibodies.

◆ Reminder: *Cytokines* are hormone-like proteins that regulate immune responses.

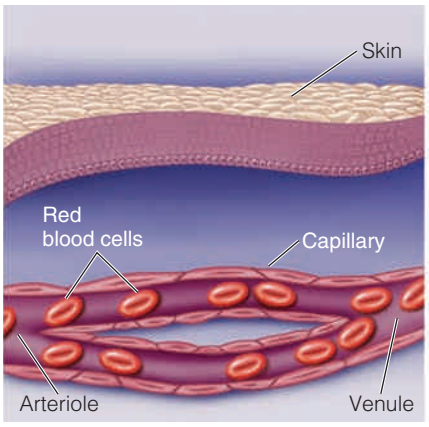
Changing dietary fat sources can have subtle effects on the inflammatory process.[2] The major precursor for the eicosanoids is arachidonic acid, which derives from the omega-6 fatty acids in vegetable oils. Some omega-3 fatty acids compete with arachidonic acid and inhibit the production of the most powerful inflammatory mediators. Partially replacing vegetable oils rich in omega-6 fatty acids with food sources high in omega-3 fatty acids (such as fish oil) helps to suppress inflammation, but it is not a reliable treatment.

phagocytes (FAG-oh-sites): white blood cells (neutrophils and macrophages) that have the ability to engulf and destroy antigens.
- **phagein** = to eat

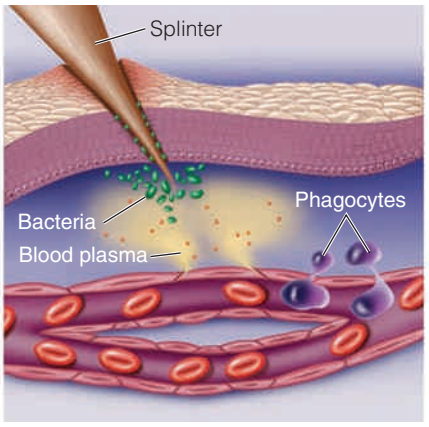
mast cells: cells within connective tissue that produce and release histamine.

eicosanoids (eye-KO-sa-noids): 20-carbon molecules derived from dietary fatty acids that help to regulate blood pressure, blood clotting, and other body functions. (Eicosanoids were introduced on p. 154.)
- **eicosa** = twenty

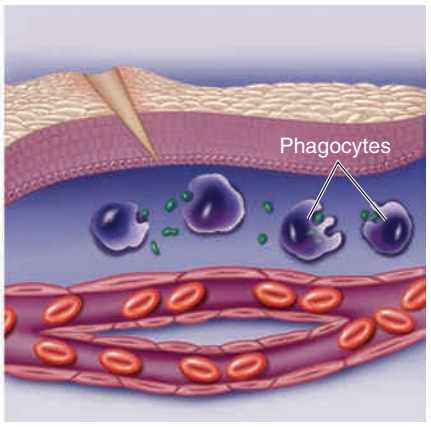
FIGURE 22-1 The Inflammatory Process



Cells lining the blood vessels lie close together, and normally do not allow the contents to cross into tissue.



When tissues are damaged, immune cells release histamine, which dilates some blood vessels, increasing blood flow to the damaged area. Fluid leaks out of capillaries (causing swelling), and phagocytes escape between the small gaps in the blood vessel walls.



Phagocytes engulf bacteria and disable them with hydrolytic enzymes and reactive forms of oxygen.

◆ C-reactive protein, the best clinical indicator of the acute-phase response, becomes elevated during many chronic diseases.

Systemic Effects of Inflammation Cytokines released during the inflammatory process induce **systemic** effects as well as the localized effects described earlier. Within hours (or, in some cases, days) after inflammation, infection, or severe injury, the liver steps up its production of certain proteins in an effort known as the **acute-phase response.**[3] These acute-phase proteins include **C-reactive protein,** ◆ complement, blood-clotting proteins such as fibrinogen and prothrombin, and others. At the same time, plasma concentrations of albumin, iron, and zinc fall (recall from Chapter 17 that albumin levels are often measured to assess health and nutrition status). The acute-phase response is accompanied by muscle catabolism to make amino acids available for glucose production, tissue repair, and immune protein synthesis; consequently, negative nitrogen balance (and wasting) frequently results. Other clinical features include an elevated metabolic rate, increased neutrophils in the blood, lethargy, anorexia, and often, fever.

Severe inflammation that persists for more than a few days can lead to a life-threatening condition: **systemic inflammatory response syndrome (SIRS).** SIRS is a whole-body response to unresolved inflammation and is diagnosed when a patient's condition becomes severe enough to raise heart rate, respiratory rate, white blood cell counts, and/or body temperature to critical levels. If identical symptoms result from infection, the condition is called **sepsis.** Complications associated with SIRS or sepsis include fluid retention and tissue edema, low blood pressure, and impaired blood flow. If the reduction of blood flow is severe enough to deprive the body's tissues of oxygen and nutrients (a condition known as **shock**), multiple organs may fail simultaneously, as discussed in Highlight 22.

IN SUMMARY

The stress and inflammatory responses are nonspecific responses to stressors that cause infection and injury. The stress response is mediated by the catecholamine hormones, cortisol, and glucagon, which together raise nutrient levels in blood, stimulate heart rate, raise blood pressure, and increase metabolic rate. Aldosterone and antidiuretic hormone help to maintain adequate blood volume. The inflammatory process—mediated by compounds released from damaged tissues, immune cells, and blood vessels—results in systemic effects that alter nutrient metabolism, heart rate, blood pressure, body temperature, and immune cell functions. Signs of inflammation in injured tissues include swelling, redness, heat, and pain. Persistent, severe inflammation may result in shock and lead to multiple organ dysfunction.

systemic (sih-STEM-ic): relating to the entire body.

acute-phase response: changes in body chemistry resulting from infection, inflammation, or injury; characterized by alterations in plasma proteins.

C-reactive protein: an acute-phase protein released from the liver during acute inflammation or stress.

systemic inflammatory response syndrome (SIRS): a whole-body response to acute inflammation; characterized by raised heart and respiratory rates, abnormal white blood cell counts, and abnormal body temperature.

sepsis: an acute inflammatory response caused by infection; characterized by symptoms similar to those of SIRS.

shock: a severe reduction in blood flow that deprives the body's tissues of oxygen and nutrients; characterized by reduced blood pressure, raised heart and respiratory rates, and muscle weakness.

abscesses (AB-sess-es): accumulated pus that is surrounded by inflamed tissue.

debridement: the surgical removal of dead, damaged, or contaminated tissue resulting from burns or wounds; helps to prevent infection and hasten healing.

Nutrition Treatment of Acute Stress

As described earlier, an excessive response to metabolic stress can worsen illness and even threaten survival. Therefore, a critical care unit must manage both the acute medical condition that initiated stress and the complications that arise as a result of the stress and inflammatory responses. Immediate concerns during severe stress are to restore lost fluids and electrolytes and to remove underlying stressors. Thus, initial treatments include administering intravenous solutions to correct fluid and electrolyte imbalances, treating infections, repairing wounds, draining **abscesses** (pus), and removing dead tissue **(debridement).** After stabilization, nutrient needs can be estimated and medical nutrition therapy provided.

Determining Nutritional Requirements

The most critical metabolic changes in patients undergoing metabolic stress include hypermetabolism, negative nitrogen balance, hyperglycemia, and insulin

resistance. Hypermetabolism and negative nitrogen balance can result in wasting, which may impair organ function and delay recovery. Hyperglycemia increases the risk of infection, a dangerous problem during critical illness. Thus, the principal goals of medical nutrition therapy are to provide a diet that preserves lean tissue, maintains immune defenses, and promotes healing.

Feeding an acutely stressed patient is challenging. Overfeeding increases the risks of refeeding syndrome ◆ and its associated hyperglycemia. Underfeeding may worsen negative nitrogen balance and increase lean tissue losses. Assessment of nutritional needs can be complicated, however, because fluid imbalances prevent accurate measurements of weight, and laboratory data may reflect the metabolic alterations of illness rather than the person's nutrition status.

◆ Reminder: *Refeeding syndrome* can develop when a severely malnourished person is aggressively fed; it is associated with fluid and electrolyte imbalances and hyperglycemia.

The amounts of protein and energy to provide during acute illness are controversial and still under investigation. Research results have been mixed, in part because the wide assortment of conditions that cause metabolic stress makes each patient's situation somewhat different. Moreover, protein and energy needs can vary substantially over the course of illness. The guidelines presented here are subject to change as new findings help to resolve the complex issues related to nutrient intakes and delivery methods. In all cases, clinicians need to closely observe patients' responses to feedings and readjust nutrient intakes as necessary.

Estimating Energy Needs for Acute Stress A common method for determining the energy needs of acutely stressed individuals is to estimate resting metabolic rate (RMR) and then multiply the result by a stress factor to account for the increased energy requirements of stress and healing.[4] This method was introduced in the "How to" on p. 621 (Chapter 18); Table 18-3 (p. 620) lists some common predictive equations used for estimating RMR.

Stress factors depend on the severity of the illness and the patient's nutrition status. Generally, energy needs are increased by fever, mechanical ventilation, restlessness, and the presence of open wounds; patients with burns and infections often have the highest energy needs. For many critically ill patients, the stress factor 1.2 provides adequate energy, and higher factors may result in overfeeding.[5] Note that patients who are critically ill are usually bedridden and inactive, so the energy needed for physical activity is minimal. Table 22-2 outlines the use of stress factors during acute metabolic stress and provides examples that are appropriate for critical care patients; keep in mind that the particular values used can vary somewhat among institutions.

A number of predictive equations with "built-in" stress factors have been developed for use in critical care populations. As an example, the Ireton-Jones equation,

TABLE 22-2 Estimating Energy Needs for Patients with Acute Metabolic Stress

Step 1. Estimate energy needs to support resting metabolic rate (RMR) using indirect calorimetry or a predictive equation (see Table 18-3, p. 620).

Step 2. Multiply the patient's RMR by an appropriate stress factor for acute illness (see the example in the "How to" box on p. 621). Examples of stress factors include:

- Advanced liver disease: 1.0 to 1.16
- Inflammatory bowel disease (active): 1.05 to 1.10
- Pancreatitis: 1.13 to 1.21
- Surgery: 1.2 to 1.4
- Leukemia: 1.25 to 1.35

SOURCES: American Dietetic Association, *Nutrition Care Manual* (Chicago: American Dietetic Association, 2007); N. Barak, E. Wall-Alonso, and M. D. Sitrin, Evaluation of stress factors and body weight adjustments currently used to estimate energy expenditure in hospitalized patients, *Journal of Parenteral and Enteral Nutrition* 26 (2002): 231–238.

HOW TO Estimate the Energy Needs of a Critical Care Patient

Equations that estimate the energy needs of critically ill patients sometimes include "built-in" stress factors. The Ireton-Jones equation, shown here, was developed for use in critically ill populations and includes factors for traumatic injury and burns:

$$\text{Energy needs (kcal per day)} = 1925 + [5 \times \text{wt (kg)}] - [10 \times \text{age (yr)}] + (281 \times \text{sex}) + (292 \times \text{trauma}) + (851 \times \text{burn})$$

where sex is male (× 1) or female (× 0), trauma is the presence of physical injury (× 1) or not (× 0), and burn is the presence of a burn injury (× 1) or not (× 0).

Example: Erin is a 27-year-old female patient who weighs 140 pounds (63.6 kilograms). Two days ago, she was severely injured in an automobile accident and is currently being cared for in a critical care unit. She did not suffer a burn injury. Using the Ireton-Jones equation, her daily energy needs can be estimated as follows:

Energy needs (kcal per day)

$$= 1925 + (5 \times 63.6 \text{ kg}) - (10 \times 27 \text{ yr}) + (281 \times 0) + (292 \times 1) + (851 \times 0)$$

$$= 1925 + 318 - 270 + 0 + 292 + 0 = 2265 \text{ kcal}$$

SOURCES: D. Frankenfield, Prediction of resting metabolic rate in critically ill adult patients: Results of a systematic review of the evidence, *Journal of the American Dietetic Association* 107 (2007): 1552–1561; C. S. Ireton-Jones and coauthors, Equations for the estimation of energy expenditures in patients with burns with special reference to ventilatory status, *Journal of Burn Care and Rehabilitation* 13 (1992): 330–333.

described in the "How to" above, includes multipliers for the presence of trauma and burn injuries; this equation provides relatively accurate results in both obese and nonobese patients.[6] Several other equations in current use include factors for other pertinent variables, such as body temperature, respiratory rate, and use of mechanical ventilation.[7]

A quick method for estimating energy needs is to multiply a person's body weight by a factor appropriate for the medical condition. For example, daily energy needs for critical care patients often fall within the range of 25 to 30 kcalories per kilogram of body weight[8]; a patient weighing 160 pounds (72.7 kilograms) may therefore require between 1818 and 2181 kcalories per day. ◆ The energy intake can be started within this range and then adjusted as the patient's body weight and other determinants of nutrition status change.

◆ 72.7 kg × 25 kcal/kg = 1818 kcal
72.7 kg × 30 kcal/kg = 2181 kcal

Protein Requirements in Acute Stress To protect lean tissue, the protein intakes recommended during acute stress are higher than DRI values. ◆ In most critically ill patients, protein needs range between 1 and 2 grams per kilogram body weight per day[9]; burn patients often require between 2 and 3 grams per kilogram body weight each day due to the substantial losses of protein associated with burn wounds.[10] Even with adequate protein, however, negative nitrogen balance cannot be prevented during acute stress, because the accompanying metabolic processes encourage the degradation of body protein. The bed rest required during critical illness also contributes substantially to muscle breakdown.

◆ Reminder: The protein RDA for adults is 0.8 grams per kilogram body weight.

The amino acids glutamine and arginine are sometimes added to the diets of acutely stressed and immune-compromised patients. Several studies have suggested that glutamine supplementation may improve immune function, preserve muscle mass, and reduce mortality rates in critically ill patients.[11] Arginine supplementation has been shown to have beneficial effects on the immune responses and nitrogen balance of critically ill and postoperative patients.[12] Although glutamine and arginine are often added to enteral formulas promoted for wound healing and enhanced immunity, their use remains controversial.

Carbohydrate and Fat Intakes in Acute Stress The bulk of energy needs are supplied from carbohydrate and fat. Carbohydrate is usually the main source of

energy, providing 50 to 60 percent of total energy requirements.[13] When parenteral feedings are necessary, dextrose is provided to critically ill patients at no more than 5 milligrams per kilogram body weight per minute to prevent hyperglycemia (see p. 697).

Fat provides both energy and essential fatty acids. In critically ill patients who are not at risk for hypertriglyceridemia (blood triglyceride levels are less than 300 milligrams per deciliter), fat intakes should range between 1.0 and 1.5 grams per kilogram body weight per day.[14] In patients with severe hyperglycemia, fat may supply up to 50 percent of kcalories, although high fat intakes may suppress immune function and increase the risks of developing infections and hypertriglyceridemia. Patients with blood triglyceride levels above 300 to 400 milligrams per deciliter may require fat restriction.[15]

Micronutrient Needs in Acute Stress Acutely stressed patients may have increased micronutrient needs, but specific requirements remain unknown.[16] In hypermetabolic patients, the need for B vitamins may be higher to support the increase in energy metabolism. A number of micronutrients, such as vitamin A, vitamin C, and zinc, have critical roles in immunity and wound healing, and their supplementation may speed recovery under certain circumstances. Patients with burns and tissue injuries may have increased requirements for trace minerals due to tissue losses; in several studies, supplementation of zinc, copper, and selenium improved immune responses in severely burned patients.[17]

Plasma levels of micronutrients are often altered during critical illness. The acute-phase response causes a redistribution of some micronutrients (such as zinc and iron) that lowers their blood levels; therefore, micronutrient status is sometimes difficult to interpret. Blood concentrations of trace minerals should be monitored in patients receiving parenteral nutrition support to ensure that excessive amounts are not given intravenously.

Approaches to Nutrition Care in Acute Stress

As mentioned earlier, the initial care following acute stress focuses on maintaining fluid and electrolyte balances. Simple intravenous solutions often contain dextrose, providing minimal kcalories. Once feedings begin, patients may require a combination of methods to meet their nutritional needs. If poor appetite, the medical condition, or a medical procedure (such as mechanical ventilation) interferes with food intake, nutrition support may be warranted.

As Chapter 20 explained, enteral nutrition support is preferred over parenteral nutrition in patients with normal intestinal function. However, parenteral nutrition support may be required if patients cannot achieve adequate nutrient intakes from enteral feedings. In one study of critically ill patients, only 53 percent were able to meet nutrient needs from enteral feedings alone, and energy intakes averaged 77 percent of the amounts prescribed.[18] Consequently, parenteral nutrition is sometimes used to supplement enteral feedings; for patients who are likely to become malnourished during critical illness, it may be the main source of nutrients.

Once patients transition to oral feedings, meeting protein and energy needs may be difficult, and enteral formulas are often given to supplement the diet. Many such formulas have high nutrient density, and some contain extra amounts of nutrients believed to promote healing, such as vitamin A, zinc, and the amino acids arginine and glutamine. A high-kcalorie, high-protein diet is often prescribed, although care must be taken not to overfeed patients who are at risk of developing refeeding syndrome or hyperglycemia. Nutrient needs should be reassessed frequently until the patient's condition stabilizes.

Patients with Burn Injuries

Burns are among the most severe injuries that a person may experience, and they have destructive effects on growth and health that may persist long after the

A second-degree burn damages the epidermis and a portion of the dermis and causes redness, swelling, and blistering.

© Bart's Medical Library/Phototake

A third-degree burn destroys both the epidermis and dermis and may involve the tissues beneath the skin.

◆ Chapter 18 provides information about the high-kcalorie, high-protein diet (see pp. 624–625).

hypovolemia (HIGH-poe-voe-LEE-me-ah): low blood volume.

epidermis (eh-pih-DER-miss): the outer layer of the skin.

dermis: the connective tissue layer underneath the epidermis that contains the skin's blood vessels and nerves.

burns have healed. Causes of burns include flames or scalding water, chemical agents, electricity, and irradiation. Frequent complications include infection and **hypovolemia,** which can increase the risk of death.[19]

Burn Classification Burns are classified according to how deeply they penetrate the skin and underlying tissue. First-degree burns affect only the **epidermis** and are pink or red, dry, and painful (for example, a sunburn). Second-degree burns (also called partial-thickness burns) involve both the epidermis and a portion of the **dermis.** They are red, wet, and blistery, and extremely painful because nerve endings are exposed. Third-degree burns (also known as full-thickness burns) destroy both the epidermis and dermis and may extend into the tissues below; their appearance may be waxy white, brown and leathery, or black and charred. These burns are deep enough to destroy nerves and are therefore painless.[20]

Burn size in adults is often estimated by dividing the body into 11 parts; each part represents about 9 percent of the total body surface area (TBSA).[21] The head and neck region and each arm are equivalent to about 9 percent TBSA each; the front torso, the back torso, and each leg represent approximately 18 percent TBSA each (see the margin drawing on p. 717). The severity of a burn is based both on its thickness and on the amount of surface area involved.

Treatment for Burn Injuries Emergency measures after a burn include the removal of clothing and smoldering material from the skin. Burns caused by acid or chemical compounds must be flushed with copious amounts of water. Wounds are cleaned and debris removed. Blisters and dead tissue are debrided, if necessary. Finally, the surface is covered with topical antibacterial agents and sterile dressings. Immediate care also includes fluid replacement, as the fluid losses through burned skin can be considerable. Some burn victims need immediate oxygen support or mechanical ventilation. Pain relief medication is also required soon after injury.

Metabolic Changes in Burn Patients Burn injuries cause severe metabolic stress and the inflammatory response, as discussed earlier in this chapter, and therefore they result in hypermetabolism, tissue breakdown, and altered nutrient metabolism. With the protective skin barrier partially destroyed, burns are accompanied by losses of evaporative water and body heat. Second- and third-degree burns can cause substantial losses of protein and micronutrients. Extensive burns can disrupt gastrointestinal function.

Medical Nutrition Therapy for Burn Patients The objectives of nutrition care for burn patients are to achieve nitrogen balance and minimize tissue losses. The nutrition prescription is typically a high-kcalorie, high-protein diet.[22] ◆ Energy needs can be calculated as described previously (see Table 22-2 on p. 713 and the "How to" on p. 714), although equations that consider additional factors such as burn severity and ventilator use are sometimes used during peak recovery periods. The suggested protein intake is 2 to 3 grams per kilogram body weight or 20 to 25 percent of total kcalories in individuals with burns greater than 10 percent TBSA.[23] For less extensive burns, a protein intake of 1.2 grams per kilogram body weight is usually adequate. Adequacy of protein intake is assessed by monitoring nitrogen balance, serum proteins, and wound-healing ability. Micronutrient supplements are often provided and may include high amounts of vitamin A, vitamin C, and zinc, which are thought to support immunity and promote wound healing. Fluid needs must be monitored carefully during the recovery period; the patient's hydration status is evaluated by monitoring urine output and serum electrolyte levels.

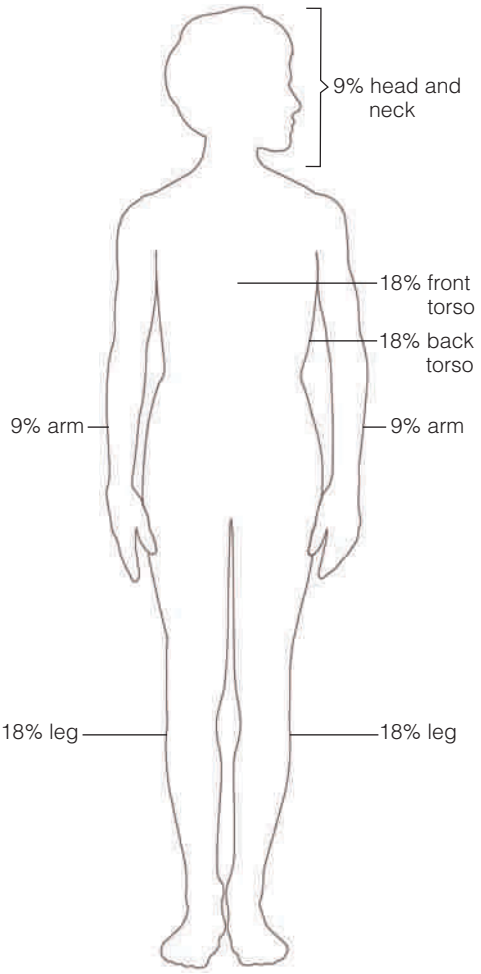
Some patients may need to be evaluated for feeding ability; problems that may interfere with eating include burns on the face, hands, and arms; bulky dressings; frequent dressing changes; and pain medications that cause sedation. Patients who are able to eat are often offered small, frequent meals rather than large meals and are provided with oral supplements and nutrient-dense snacks to help them meet energy and protein needs. A combination of oral feedings and tube feedings is often necessary. Some burn patients develop gastroparesis or intestinal ileus (stomach or intestinal paralysis) and may require nasoenteric feedings (discussed

CASE STUDY Mortgage Broker with a Severe Burn

David Bray, a 42-year-old mortgage broker, has been admitted to intensive care. He suffered a severe burn covering 35 percent of his body when he was trapped inside a burning building. His wife told the nurse that Mr. Bray's height is 6 feet and that he usually weighs about 175 pounds. The physician ordered lab work, including serum protein concentrations, but the results have not yet been received.

1. Identify Mr. Bray's immediate needs after the injury. Describe the initial concerns of the health care team and the measures they might take soon after Mr. Bray's arrival at the hospital.
2. Considering Mr. Bray's condition, what problems might the health care team encounter when they attempt to obtain information that can help them assess his nutrition status? What additional concerns might they have if Mr. Bray was malnourished before he experienced the burn?
3. Estimate Mr. Bray's energy and protein needs (use a protein factor of 2.5 grams per kilogram). What problems may interfere with Mr. Bray's ability to meet his nutrient needs?
4. Due to complications that developed during tube feeding, Mr. Bray was able to obtain only 65 percent of his energy requirements. What other feeding options may be considered?

in Chapter 20). Parenteral support may be required if intestinal function is lacking, if complications that interfere with enteral feedings develop, or if nutrient requirements cannot be met by tube feeding alone. The accompanying Case Study reviews the nutrition care of a burn patient.



Burn size can be estimated by sectioning the total body surface area (TBSA) as shown.

IN SUMMARY

Severe metabolic stress causes hypermetabolism and negative nitrogen balance and may result in wasting. The objectives of nutrition care during stress are to provide a diet that can preserve muscle tissue, maintain immune defenses, and promote healing. Energy intake should sustain nitrogen balance but should not result in overfeeding. Protein recommendations are increased to help prevent tissue losses and allow healing of damaged tissue. Enteral and parenteral feedings are sometimes needed to meet the high nutrient requirements of acutely stressed patients. Burn patients require fluid replacement immediately after a burn injury, and a high-kcalorie, high-protein diet during recovery.

Nutrition and Respiratory Stress

Some medical problems upset the gas exchange process between the air and blood and result in respiratory stress, which is characterized by a reduction in the blood's oxygen supply and an increase in carbon dioxide levels. In some individuals, the excessive carbon dioxide in the blood disrupts the breathing pattern and thereby interferes with food intake. Moreover, the labored breathing caused by respiratory disorders entails a higher energy cost than normal breathing does, raising energy needs and increasing carbon dioxide production further. Lung diseases make physical activity difficult and can lead to muscle wasting. Weight loss and malnutrition therefore become dangerous outcomes of some types of respiratory illnesses.

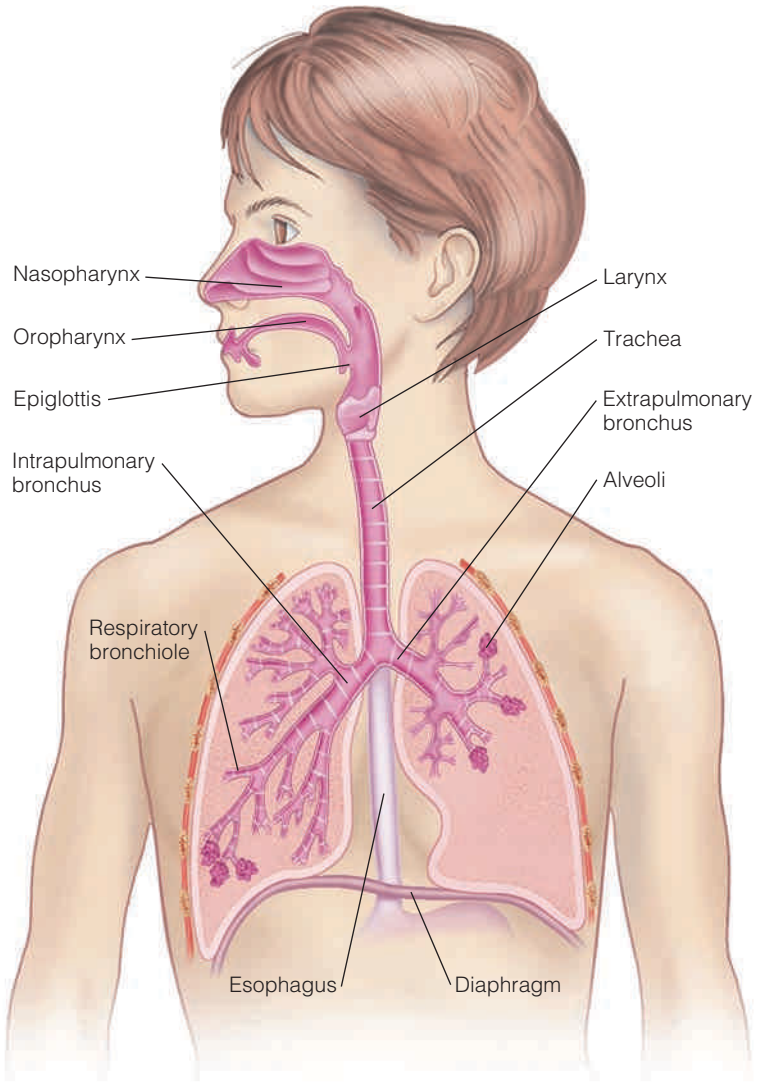
Chronic Obstructive Pulmonary Disease

Chronic obstructive pulmonary disease (COPD) refers to a group of conditions characterized by the persistent obstruction of airflow through the lungs.

chronic obstructive pulmonary disease (COPD): a group of lung diseases characterized by persistent obstructed airflow through the lungs and airways; includes chronic bronchitis and emphysema.

FIGURE 22-2 The Respiratory System

Inhaled air travels via the trachea to the bronchi and bronchioles, the major airways of the lungs. Oxygen and carbon dioxide are exchanged across the thin-walled alveoli, which are surrounded by capillaries.



SOURCE: Based on a drawing in Carol Mattson Porth, *Pathophysiology,* 5th ed. (Lippincott Williams & Wilkins, 1998).

bronchi (BRON-key), **bronchioles** (BRON-key-oles): the main airways of the lungs. The singular form of bronchi is *bronchus.*

alveoli (al-VEE-oh-lie): air sacs in the lungs. One sac is an *alveolus.*

chronic bronchitis (bron-KYE-tis): a lung disorder characterized by persistent inflammation and excessive secretions of mucus in the main airways of the lungs; diagnosis is based on the presence of a chronic, productive cough for at least three months of the year for two successive years.

emphysema (EM-fih-ZEE-mah): a progressive lung condition characterized by the breakdown of the lungs' elastic structure and destruction of the walls of the bronchioles and alveoli, reducing the surface area involved in respiration.

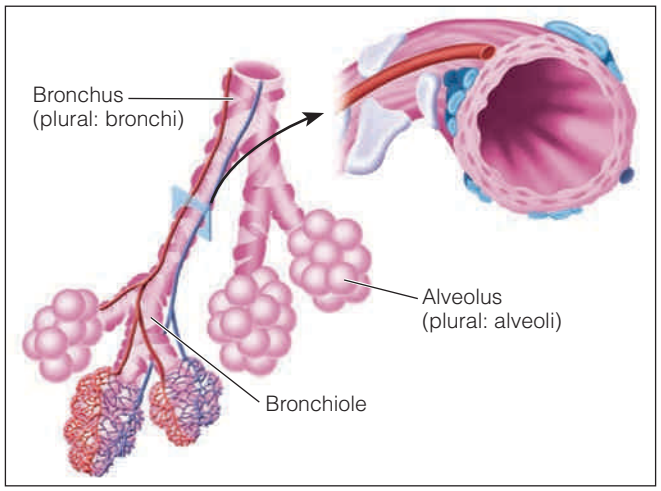
dyspnea (DISP-nee-ah): shortness of breath.

Figure 22-2 illustrates the main airways **(bronchi** and **bronchioles)** and air sacs **(alveoli)** of the normal respiratory system, and Figure 22-3 shows how they are altered in COPD. The two main types of COPD are **chronic bronchitis** and **emphysema,** and many patients display features of both conditions[24]:

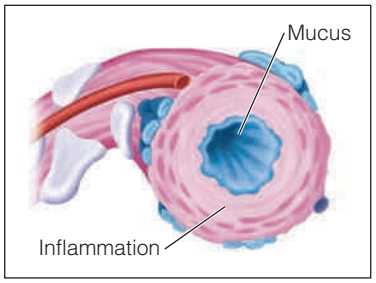
- *Chronic bronchitis* is characterized by persistent inflammation and excessive secretions of mucus in the main airways of the lungs, which may ultimately thicken and become too narrow for adequate mucus clearance. Chronic bronchitis is diagnosed when a chronic, productive cough persists for at least three months of the year for two consecutive years.
- *Emphysema* is characterized by the breakdown of the lungs' elastic structure and destruction of the walls of the bronchioles and alveoli, changes that significantly reduce the surface area needed for respiration. Emphysema is diagnosed on the basis of clinical signs and the results of lung function tests.

Both chronic bronchitis and emphysema are associated with abnormal levels of oxygen and carbon dioxide in the blood and shortness of breath **(dyspnea).**

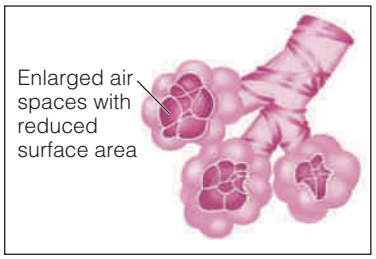
FIGURE 22-3 Chronic Obstructive Pulmonary Disease



Healthy bronchi provide an open passageway for air. Healthy alveoli permit gas exchange between the air and blood.



Chronic bronchitis is characterized by inflammation, excessive secretion of mucus, and narrowing of the bronchi – factors that reduce normal airflow.



Emphysema is characterized by gradual destruction of the walls separating the alveoli and reduced lung elasticity.

COPD may eventually lead to respiratory or heart failure and ranks as the fourth leading cause of death in the United States.[25]

COPD is a debilitating condition. Generally, dyspnea worsens as the condition progresses, resulting in dramatic reductions in physical activity and quality of life. Activities of daily living such as bathing or dressing may cause exhaustion or breathlessness. Weight loss and wasting are common in the advanced stages of disease and may result from hypermetabolism, poor food intake, and the actions of various inflammatory proteins. As with other chronic illnesses, anxiety and depression are a concern, and psychological distress may reduce a COPD patient's ability to cope with the demands of treatment.

Causes of COPD Cigarette smoking is the primary risk factor in 90 percent of COPD cases[26] and is especially damaging when combined with respiratory infections or an occupational exposure to dusts or chemicals. Only a minority of smokers (about 15 percent) develop COPD, however; thus genetic susceptibility also contributes to its development. Genetic factors are especially likely in patients with early-onset COPD. Alpha-1-antitrypsin deficiency, an inherited disorder, occurs in 1 to 2 percent of patients with COPD.[27] These individuals have inadequate blood levels of a plasma protein (alpha-1 antitrypsin) that normally inhibits enzymatic breakdown of the lungs' connective tissue.

Treatment of COPD The primary objectives of COPD treatment are to prevent the disease from progressing and relieve major symptoms (dyspnea and coughing). Individuals with COPD are encouraged to quit smoking to prevent disease progression and to get vaccinated against influenza and pneumonia to avoid complications. The most frequently prescribed medications are bronchodilators, which improve airflow, and corticosteroids (anti-inflammatory medications), which help to prevent symptom recurrence; note that corticosteroids promote catabolic processes and can exacerbate the muscle loss that often accompanies COPD. For people with severe COPD, supplemental oxygen therapy (12 hours daily) can maintain normal oxygen levels in the blood and reduce mortality risk. The Diet-Drug Interactions feature on p. 720 lists nutrition-related effects of the medications used to treat COPD.

DIET-DRUG INTERACTIONS

Check this table for notable nutrition-related effects of the medications discussed in this chapter.

	Gastrointestinal Effects	Interactions with Dietary Substances	Metabolic Effects
Bronchodilators (theophylline, dyphylline)	Increased gastric acid secretion, acid reflux.	Caffeine may enhance drug effects.	
Corticosteroids (prednisone)			Glucose intolerance, sodium retention, negative nitrogen balance, appetite stimulation, weight gain, growth suppression in children.

Medical Nutrition Therapy for COPD The main goals of nutrition therapy for COPD are to correct the malnutrition that affects up to 60 percent of patients with COPD,[28] promote the maintenance of a healthy body weight, and prevent muscle wasting. Research studies have found that COPD patients with low body weights have higher mortality rates[29]; thus, encouraging adequate food intake is usually the main focus of the nutrition care plan. The hypermetabolism in COPD patients is due to the increased workload of the muscles involved in breathing; resting metabolic rates are about 15 percent above the values predicted by RMR equations.[30] Note that some patients with COPD may be overweight or obese, which puts an additional strain on the respiratory system; such patients may benefit from energy restriction and gradual weight reduction.

Food intake often declines as COPD progresses, although the causes of poor intake vary among patients. Dyspnea may interfere with chewing or swallowing. Appetite may be affected by medications, depression or anxiety, or altered taste perception. ◆ Physical changes in the diaphragm and lungs may reduce abdominal volume, leading to early satiety. Some patients may become too disabled to shop or prepare food or may lack adequate support at home. The health practitioner must assess the unique needs of a COPD patient before proposing a nutrition care plan.

◆ The altered sense of taste in patients with COPD may be due to chronic mouth breathing, which dries the mouth. Taste is also affected by the use of certain medications, including some bronchodilators.

Some patients may benefit by eating small, frequent meals rather than two or three large ones. The lower energy content of small meals reduces the carbon dioxide load,[31] plus abdominal discomfort and dyspnea may be reduced when less food is consumed. If bloating is a problem, patients should avoid foods that increase gas formation. Some individuals may eat better if they receive supplemental oxygen at mealtimes. Consuming adequate fluids should be encouraged to help prevent the secretion of overly thick mucus; however, some patients should consume liquids between meals so as not to interfere with food intake. For undernourished patients, a high-kcalorie, high-protein diet may be helpful, but excessive energy intakes may increase carbon dioxide output and increase respiratory stress. Liquid supplements are sometimes given between meals to improve weight gain or exercise endurance, but high-energy supplements (those containing more than 250 kcalories) may induce satiety and reduce energy intake at mealtime.[32]

© Courtesy of Airsep Corporation

Patients who need supplemental oxygen can use lightweight, portable equipment that allows them to move about freely.

Pulmonary Formulas Some enteral formulas available for use in pulmonary disease provide more kcalories from fat and fewer from carbohydrate than standard formulas. The ratio of carbon dioxide production to oxygen consumption in cells is lower when fat is consumed, so theoretically these formulas should lower respiratory requirements. However, research studies have not confirmed that the reduced-carbohydrate formulas improve clinical outcomes more than moderate energy intakes, so the benefits of using these pulmonary formulas are uncertain.[33]

Incorporating an Exercise Program Loss of muscle can be more readily prevented or reversed if the treatment plan includes a carefully designed exercise program.[34] With exercise, patients are likely to see improvements in their endurance and become less fearful of their physical limitations. For some patients, the combination of an exercise plan and oral supplements may be better for maintaining weight and improving muscle status than either component of treatment alone.[35] The accompanying Case Study allows you to review the nutrition care for a patient with COPD.

Respiratory Failure

In respiratory failure, the gas exchange between the air and the circulating blood is severely impaired, causing abnormal levels of tissue gases that can be life threatening. Respiratory failure can develop from chronic disease (such as COPD) or may arise suddenly (*acute* respiratory failure). Various conditions that affect lung function can be the underlying cause of failure. For example, respiratory failure may result from obstruction in the upper airways or from weakness or paralysis of the muscles involved in respiration. An embolus lodged within the lungs may prevent blood flow, or toxic substances may damage lung tissue. Surgery sometimes results in respiratory failure due to the depressive effects of anesthesia or because some abdominal procedures can affect breathing. Severe trauma and infection are common triggers of **acute respiratory distress syndrome (ARDS),** an acute form of respiratory failure marked by extensive lung damage. ARDS is a life-threatening condition that usually requires the use of mechanical ventilation to restore normal oxygen and carbon dioxide levels.

Consequences of Respiratory Failure Impaired gas exchange results in **hypoxemia** (low oxygen levels in the blood) and **hypercapnia** (excessive carbon dioxide in the blood). An inadequate oxygen supply within tissues **(hypoxia)** inhibits cellular function and can ultimately cause cell death. Hypercapnia can lead to **acidosis,** which interferes with the functions of the central nervous system. To compensate for respiratory failure, a person breathes more rapidly, and the heart rate increases. The skin may become sweaty and develop a bluish cast **(cyanosis).** Headache, confusion, and drowsiness may occur. Severe cases of respiratory failure can cause heart arrhythmias and ultimately, coma.

Acute Respiratory Distress Syndrome (ARDS) Acute respiratory distress syndrome (ARDS) typically occurs in individuals who have no history of lung disease, and it often follows acute lung injury due to sepsis, trauma, severe pneumonia,

CASE STUDY Elderly Person with Emphysema

John Norback is an 82-year-old man who has emphysema that severely affects both lungs. He is 5 feet 9 inches tall and currently weighs 150 pounds, about 20 pounds less than his weight in earlier years. He lives with a daughter and son-in-law and eats meals with their family. He becomes breathless when eating and when walking around the house, and he feels tired all the time. A medical clinic recently ordered oxygen therapy for home use, but supplies have not yet arrived. Mr. Norback's daughter is concerned about her father's recent weight loss and breathlessness.

1. Assess Mr. Norback's risk of malnutrition, using information from Table 17-9 in Chapter 17 (p. 602). What factors may have contributed to his weight loss?
2. What are possible reasons for Mr. Norback's difficulty with eating? List some dietary suggestions that may help to improve his appetite and food intake. How might the use of oxygen therapy help?
3. Based on the history given, what factors may account for Mr. Norback's tiredness? What suggestions would you give Mr. Norback and his daughter regarding physical activity?

acute respiratory distress syndrome (ARDS): respiratory failure triggered by severe lung injury; a medical emergency that causes dyspnea and pulmonary edema and usually requires assisted (mechanical) ventilation.

hypoxemia (high-pock-SEE-me-ah): a low level of oxygen in the blood.

hypercapnia (high-per-CAP-nee-ah): excessive carbon dioxide in the blood.

hypoxia (high-POCK-see-ah): a low amount of oxygen in body tissues.

acidosis: acid accumulation in body tissues; depresses the central nervous system and can lead to disorientation and, eventually, coma.

cyanosis (sigh-ah-NOH-sis): a bluish cast in the skin due to the color of deoxygenated hemoglobin. Cyanosis is most evident in individuals with lighter, thinner skin; it is mostly seen on lips, cheeks, and ears and under the nails.

© Yoav Levy/Phototake

Mechanical ventilation controls the rate and amount of oxygen supplied to a patient's airways.

inhalation of smoke or toxic chemicals, or aspiration of gastric contents.[36] It can develop over 12 to 48 hours or may take several days to appear. The lungs exhibit extensive inflammation and fluid buildup (pulmonary edema) that interfere with lung ventilation and with gas exchange in the alveoli. Blood oxygen levels are typically very low. The later stages of ARDS are associated with a proliferation of lung cells, which causes fibrosis and disrupts lung structure. A dangerous complication of ARDS is a progression to multiple organ dysfunction syndrome, which is described in the highlight following this chapter.

Treatment of Respiratory Failure The treatment of respiratory failure focuses on supporting lung function and correcting the underlying disorder. Because respiratory failure can be caused by a number of different conditions, treatment plans vary considerably. In individuals with chronic lung disease, providing oxygen therapy via a face mask or nasal tubing can relieve symptoms, but patients with ARDS usually require mechanical ventilation until they are able to breathe independently. Fluids may need careful monitoring to maintain fluid balance and prevent overload; diuretics are sometimes prescribed to mobilize the fluid that has accumulated in lung tissue. Medications may be given to treat infections, keep airways open, or relieve inflammation. Complications are common in ARDS and must be forestalled to prevent multiple organ dysfunction.

Medical Nutrition Therapy for Acute Respiratory Failure Dietary recommendations are individualized according to the patient's condition. The primary concern is to supply enough energy and protein to support lung function without overtaxing the compromised respiratory system.[37] Fluid restrictions may be necessary to help reverse pulmonary edema. As usual, when nutrition support is necessary, enteral nutrition is preferred over parenteral nutrition.

Energy Needs Energy needs can be estimated by using a predictive equation to determine the RMR and adjusting the result with an appropriate stress factor. The body weight used in the equation may need to be corrected for edema, which is often present in patients with acute respiratory failure. A stress factor of 1.2 can be used initially, although needs may be higher in malnourished patients or if fever or infections are present.[38] Energy intakes above 1.5 times RMR are not recommended for patients with acute respiratory failure because excessive energy intakes generate extra carbon dioxide and increase the risk for complications.

For patients using mechanical ventilation, the stress factors 1.34 and 1.32 are often appropriate for men and women, respectively.[39] Predictive equations that include respiratory rates (in breaths per minute or liters per minute) and lung volume (in liters) are also used for determining energy needs in ventilated patients. Note that mechanical ventilation can sometimes reduce energy expenditure, because patients using ventilators are often heavily sedated and immobile, which lowers energy requirements.

Fluids Dehydration may develop due to a low fluid intake, an increase in bronchial secretions, or diuretic therapy. Although dehydration can impede the clearance of lung secretions, pulmonary edema is often present, so fluid restriction may be required to prevent the accumulation of additional fluids in lung tissue. The edema may make it difficult to assess whether a critically ill patient is maintaining weight.

Nutrition Support Patients with acute respiratory failure are often unable to eat meals and may need nutrition support. Tube feedings are usually used if the intestine is functional, and intestinal feedings are preferred over gastric feedings because they reduce the risk of aspiration. Nutrient-dense formulas (2 kcalories per milliliter) are generally recommended for patients with fluid restrictions. Formulas enriched with omega-3 fatty acids and vitamins A, C, and E have been found to be helpful in patients with ARDS.[40] If the risk of aspiration is too high to continue enteral feedings, parenteral nutrition support may be considered.

IN SUMMARY

Respiratory stress from chronic or acute disease affects body weight, muscle mass, and the normal functioning of all body tissues. Chronic obstructive pulmonary disease (COPD) is a debilitating, progressive illness that can lead to malnutrition, muscle wasting, and activity intolerance. Depending on individual needs, the goals of nutrition therapy are to improve food intake, maintain proper weight, preserve muscle tissue, and improve exercise endurance. Acute respiratory failure can develop from COPD or arise in persons with no history of lung disease. It often follows acute lung injury due to infection, trauma, or inhalation of toxic substances. Medical nutrition therapy may include nutrition support and fluid restrictions.

Clinical Portfolio

CENGAGENOW™
academic.cengage.com/login

- Adam is a 49-year-old male who is 6 feet 2 inches tall and has a usual body weight of 180 pounds. He was physically injured by an explosion in the chemistry lab where he works and is now in the intensive care unit. Using the method described in the "How to" on p. 714, estimate Adam's energy requirement. Estimate his protein requirement, using the factor 1.5 grams per kilogram of body weight.
- Turning again to the case described in the first item, assume that Adam requires a tube feeding and can tolerate a standard enteral formula. Check Appendix K to find at least three formulas that the nutrition support team might select for tube feeding. Determine the volume of each formula that would be needed to meet Adam's energy and protein needs. Would this volume also meet the recommendations for vitamins and minerals?
- Ayla is a 23-year-old law student admitted to the hospital following an automobile accident in which she broke several bones and ruptured part of her small intestine. She has been in the hospital for several weeks and has just begun eating table foods. Her brother, who was driving the vehicle, was also seriously injured and nearly lost his life. Aside from the increased nutritional needs imposed by the stress of the accident, discuss how the following factors might interfere with Ayla's ability to improve her nutrition status:
  - Ayla's injuries are painful.
  - Ayla's medications cause drowsiness.
  - Ayla is depressed.
  - Ayla is often out of her room for X-rays and other diagnostic tests when the menus and food trays arrive.
  - Ayla's food intake is sometimes restricted due to the procedures she is undergoing.

  How might these problems be resolved to improve Ayla's food intake?

NUTRITION ON THE NET

NUTRITION ASSESSMENT CHECKLIST for People Undergoing Metabolic or Respiratory Stress

Medical History
Check the medical record to determine:

- Cause of stress
- Severity of stress
- Route of feeding (oral, tube feeding, or parenteral)
- Whether any organ system is compromised

For patients with COPD, check to determine:

- Degree of breathing difficulty
- Use of oxygen therapy
- Activity tolerance

Review the medical record for complications related to underfeeding or overfeeding, such as:

- Dehydration or fluid overload
- Electrolyte imbalances
- Fatty liver
- Hyperglycemia
- Hypertriglyceridemia

Medications
Record all medications and note:

- Side effects that may alter food intake or nutrition status
- Use of theophylline, in patients who may need to avoid caffeine

Dietary Intake
If the patient is not meeting nutrition goals:

- Monitor intakes to ensure that the patient is receiving the diet prescribed.
- Investigate appetite problems or difficulties with eating.
- Consider interventions to improve food intake.
- Consider the need for supplementation.
- In patients with COPD, consider problems that may hamper the patient's ability to prepare or consume foods.

Anthropometric Data
Measure baseline height and weight, and monitor daily weights. Remember that body weight can fluctuate in acutely ill patients who undergo fluid resuscitation. Once a patient's weight has stabilized:

- Reevaluate protein and energy needs.
- Consider the need to alter the energy prescription to meet weight goals.

Laboratory Tests
Laboratory tests that may be affected by stress and therefore require careful interpretation include:

- Albumin
- Transferrin
- Prealbumin
- C-reactive protein
- Serum iron and zinc
- Total lymphocyte count (white blood cell counts are often elevated)

Monitor laboratory tests for signs of:

- Dehydration or fluid overload
- Electrolyte and acid-base imbalances
- Hyperglycemia
- Hypertriglyceridemia
- Nutrient deficiencies
- Negative nitrogen balance
- Organ dysfunction or organ function that has normalized

Physical Signs
Regularly assess vital signs, including:

- Blood pressure
- Pulse
- Body temperature
- Respiration

Look for physical signs of:

- Protein-energy malnutrition
- Dehydration or fluid overload
- Nutrient deficiencies and excesses

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Describe the effects of the stress response on the body. Specify the main hormones involved and their metabolic effects. (pp. 709–710)
2. Discuss the main effects of the inflammatory response following infection or injury. Identify the chemical mediators involved, and explain how they help to regulate the inflammatory process. (pp. 710–712)
3. Characterize the acute-phase response, giving examples of the clinical symptoms and changes in blood chemistry that usually result. (p. 712)

4. How does metabolic stress affect nutrition status? Explain why nutrition status may be difficult to evaluate in an acutely stressed individual. (pp. 712–713)
5. Describe how energy and protein needs are estimated during acute stress. Which micronutrients are sometimes supplemented? (pp. 713–715)
6. Characterize first-, second-, and third-degree burns. What measures are taken immediately after a burn occurs? (p. 716)
7. Identify the objectives of nutrition care for burn patients. Explain how the energy and protein needs of patients with burns are estimated. What measures are taken to provide adequate nutrient intakes? (pp. 716–717)
8. What is chronic obstructive pulmonary disease (COPD)? Describe its causes and treatment. Discuss the possible effects of COPD on body composition. (pp. 717–720)
9. Describe respiratory failure and its consequences. Identify the key elements of medical treatment and medical nutrition therapy. What are potential causes of acute respiratory distress syndrome (ARDS)? (pp. 721–722)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 726.

1. Which of the following metabolic changes accompanies acute stress?
   a. reduced plasma concentrations of glucose and fatty acids
   b. reduced blood volume and blood pressure
   c. increased insulin action
   d. catabolism of protein in skeletal muscle and connective tissue
2. Tissue injury is followed by:
   a. fluid accumulation in damaged tissue.
   b. reduced blood flow to injured tissue.
   c. reduced capillary permeability.
   d. decreased body temperature.
3. What is a possible effect of replacing vegetable oils rich in omega-6 fatty acids with oils rich in omega-3 fatty acids?
   a. improvement in blood circulation
   b. suppression of inflammation
   c. protection against sepsis
   d. hypertriglyceridemia
4. The acute-phase response results in increased plasma concentrations of:
   a. albumin.
   b. iron.
   c. C-reactive protein.
   d. zinc.
5. Which of the following statements concerning protein and energy recommendations during acute metabolic stress is true?
   a. Protein and energy recommendations are similar to those for healthy people.
   b. Protein and energy recommendations are reduced because a stressed individual cannot metabolize nutrients normally.
   c. Acutely stressed individuals can benefit from as much protein and energy as can be provided.
   d. Protein and energy recommendations are high in order to minimize muscle tissue losses.
6. The immediate treatment provided to a patient with a severe burn includes:
   a. parenteral feedings.
   b. fluid replacement.
   c. blood transfusions.
   d. micronutrient supplementation.
7. The primary risk factor for COPD is:
   a. alpha-1 antitrypsin deficiency.
   b. occupational exposure to dusts or chemicals.
   c. cigarette smoking.
   d. respiratory infections.
8. A primary feature of emphysema is:
   a. obstruction within the bronchi.
   b. obstruction within the bronchioles.
   c. destruction of the walls separating the alveoli.
   d. excessive lung elasticity.
9. The weight loss and wasting that often occur in COPD can be caused by:
   a. reduced food intake.
   b. increased metabolic rate.
   c. reduced exercise tolerance.
   d. all of the above.
10. Medical nutrition therapy for a person with respiratory failure includes:
    a. careful attention to providing enough, but not too much, energy.
    b. a generous fluid intake to facilitate mucus clearance.
    c. a high-fat intake to prevent weight loss.
    d. a high-carbohydrate intake to limit carbon dioxide production.

Multiple Organ Dysfunction Syndrome

© Hein Hopmans/Phototake

Multiple organ dysfunction syndrome (MODS), also called *multiple organ failure,* is a frequent cause of death in intensive care patients. Described as the progressive dysfunction of two or more of the body's organ systems, MODS most often involves the lungs, liver, kidneys, and gastrointestinal (GI) tract. MODS is not a disease per se, but rather a late stage of severe illness or injury that results from a severe inflammatory response (discussed in Chapter 22).[1] MODS can be initiated by a number of very different critical illnesses and conditions, including acute respiratory failure, trauma, sepsis, burn injuries, extensive surgery, and pancreatitis. This highlight discusses how MODS develops, the manner in which it is treated, and the importance of its prevention.

Multiple organ dysfunction syndrome was recognized as a clinical entity only after World War II. Prior to the mid-20th century, patients with severe illnesses or multiple injuries frequently died of shock or circulatory failure. After fluid replacement and blood transfusions became standard treatments, the kidneys became the organs at highest risk, and kidney failure became the most common cause of death. Eventually, physicians learned to better support kidney function by providing appropriate electrolyte solutions and improving urine output. With improved kidney care, the lungs became the most vulnerable organ after severe injury. Improved treatment of respiratory failure eventually led to the current situation: advances in critical care allow patients to survive severe illnesses and injuries, but the body's defenses often overburden organs that were not originally injured.

Development of MODS

As discussed in Chapter 22, injury and infection cause the release of chemical mediators that have systemic (whole-body) effects. A severe, persistent inflammatory response can lead to systemic inflammatory response syndrome (SIRS), which is associated with a constellation of symptoms including fever, raised heart and respiratory rates, and abnormal white blood cell counts. SIRS is a normal adaptive response to a severe insult, but if not reversed quickly enough it can progress to shock, which is characterized by extremely low blood pressure and an inadequate blood supply for the tissues and organs of the body.[2]

As might be expected from a systemic reduction in blood availability, shock can impair numerous organ systems. The abnormal delivery of oxygen and nutrients to tissues and insufficient removal of wastes result in irreversible injury to cells and tissues. Although each organ system is affected differently, ultimately one or more organs may begin to fail. The failure of one organ may place excessive demands on another, causing the second to fail as well. The progression of SIRS to MODS reflects the inability of the body's defenses and medical treatments to counter the detrimental effects of a sustained and potent inflammatory response.

The sequence of organ dysfunction often follows a similar pattern among patients: first the lungs fail, then the liver, and finally the kidneys, GI tract, or heart.[3] Other organs or systems may also become involved, and each additional failure reduces the likelihood of survival. Table H22-1 lists the organs and systems most often involved in MODS and the potential consequences of their failure.

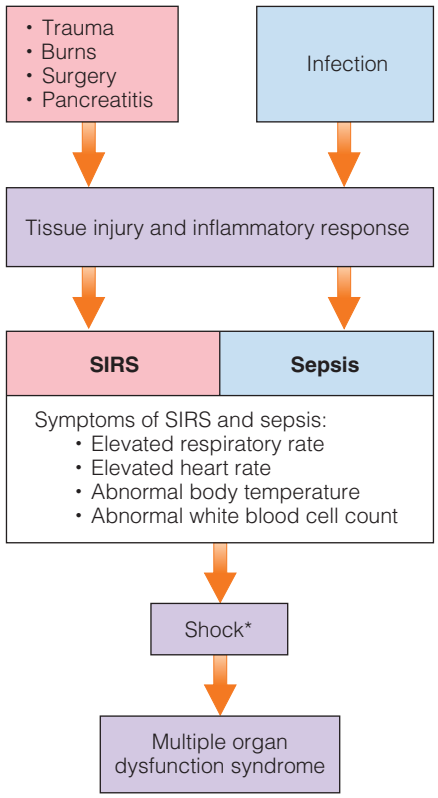
Factors That Influence Organ Dysfunction

The specific pathophysiology of MODS is poorly understood. Although early reports attempted to link the development of MODS directly to sepsis, sepsis is not present in all cases. Infection often results from impaired immune function and therefore is a frequent consequence of MODS, but it is not necessarily the underlying trigger of organ dysfunction. Recall from Chapter 22 that sepsis gives rise to symptoms identical to those seen in SIRS. Figure H22-1 on p. 728 illustrates the relationships among SIRS, infection, sepsis, and MODS.

TABLE H22-1 Physiological Effects of Organ or System Failure

Organ or System	Effects of Failure
Lungs	Inability to maintain gas exchange
Liver	Altered metabolic processes
Kidneys	Inability to regulate blood volume, maintain electrolytes, remove wastes
Heart	Low cardiac output, low blood pressure, inadequate circulation, shock
GI tract	Impaired digestion and absorption, abnormal bleeding, bacterial translocation
Immune system	Infection, sepsis
Coagulation system	Excessive bleeding or coagulation
Central nervous system	Decreased perceptions, brain injury, coma

FIGURE H22-1 Relationships among SIRS, Sepsis, and Multiple Organ Dysfunction Syndrome



*After critical injury, shock may sometimes precede and be the cause of SIRS.

Finding the exact cause of MODS is difficult because its clinical course differs greatly among patient populations. Epidemiological studies have, however, identified a number of factors that increase risk. For example, people who develop MODS are often older, have multiple or severe injuries, and develop severe infections. Table H22-2 lists the major risk factors associated with MODS, some of which are discussed in the following sections.

TABLE H22-2 Factors That Influence Risk of Multiple Organ Dysfunction Syndrome

Age over 55 years
Prior chronic disease
Persistent SIRS
Major infection
Blood transfusions
Severity of tissue injury
Length of time between injury and arrival at hospital
Malnutrition

Age

Patients over 55 years old are several times more likely to develop MODS than are younger patients. In elderly patients, the increased risk may be due to the presence of chronic illnesses that directly affect organ function, such as heart disease, lung disease, diabetes, or liver damage. Aging also decreases the functional reserve of organs, thereby reducing an older patient's ability to deal with the additional stress that arises during critical illness.

Severity of SIRS

The length of time that SIRS persists is related to the development of MODS. In one study, patients who had SIRS that persisted for more than three days were more likely to develop MODS than patients who had SIRS for less than two days.[4]

Infection

Prolonged SIRS can suppress immune function and increase the risk of developing an infection. During hospital stays, critically ill patients often contract pneumonia—the principal infection associated with MODS. The risks of infection and sepsis greatly increase with the use of invasive catheters, which are frequently needed during intensive care to provide oxygen support, intravenous fluid resuscitation, nutrition support, and urine clearance.

Blood Transfusions

Blood transfusions are immunosuppressive and may increase a patient's risks of developing infection or sepsis. Blood transfusions frequently have adverse effects that can add further stress; they may cause acute lung injury, allergic reactions, red blood cell hemolysis (breakdown), and other complications.

Treatment for MODS

Once MODS has developed, extensive medical support is needed until the inflammatory response has abated. Unfortunately, aggressive treatments can have damaging effects of their own and may cause further injury to organs that are already weakened by illness. Health practitioners must be aware of the adverse effects of aggressive therapies and remain alert to a patient's responses to treatments. Therapies that are often used to manage MODS include:

- *Lung support.* Mechanical ventilation is used to assist injured lungs and sustain gas exchange.
- *Fluid resuscitation.* Fluids and electrolytes are supplied to restore blood volume and maintain electrolyte balance.
- *Support of heart and blood vessel function.* Medications help to sustain or increase cardiac output and maintain adequate blood pressure.
- *Kidney support.* Hemofiltration or dialysis helps to prevent the buildup of toxic metabolites in blood.

- *Protection against infection.* Antibiotic therapy may reverse or prevent infections.
- *Nutrition support.* Enteral and parenteral nutrition support provides nutrients, helps to prevent excessive wasting, and promotes recovery.

Because mortality rates for MODS are so high, prevention must be considered at the earliest stages of injury and treatment, before an excessive inflammatory response can cause further damage. Health practitioners have learned to identify the conditions that can increase organ stress whether they are due to a disease process, an inflammatory response, or an aggressive treatment that is intended to provide organ support. Although improvements in care over the past few decades have reduced some of the complications that arise during intensive care, rates of mortality from MODS have not changed. Thus a focus on prevention is critical until a better understanding of the pathophysiology of MODS is achieved, which may lead to additional therapeutic options.

Nutrition in the Clinical Setting

Gastrointestinal illnesses account for a significant fraction of hospital admissions and visits to health practitioners each year. Diagnosis is not always straightforward, however, as many patients with gastrointestinal complaints exhibit no physical abnormalities. Evaluation therefore requires a detailed review of a patient's symptoms and responses to dietary adjustments. Because gastrointestinal complications frequently accompany other illnesses, the medical history can sometimes uncover the underlying source of distress.

CHAPTER 23

Upper Gastrointestinal Disorders

CHAPTER OUTLINE

Conditions Affecting the Esophagus • Dysphagia • Gastroesophageal Reflux Disease

Conditions Affecting the Stomach • Dyspepsia • Nausea and Vomiting • Gastritis • Peptic Ulcer Disease

Gastric Surgery • Gastrectomy • Bariatric Surgery

HIGHLIGHT 23 Dental Health and Chronic Illness

The remarkable gastrointestinal (GI) tract provides a means of delivering nutrients to the body's interior. When various medical conditions impair some of the GI tract's functions, dietary adjustments can help to ease symptoms and prevent malnutrition. This chapter discusses common upper GI tract symptoms and disorders; the next chapter describes conditions that affect the lower GI tract. Highlight 23 presents several mouth and dental problems and their associations with chronic disease.

Figure 23-1 on p. 732 illustrates the upper GI tract and reviews its functions. ◆ In the mouth, the teeth and jaw muscles work together to break down food to a consistency that is easily swallowed. Upon swallowing, a bolus of food passes through the pharynx to the esophagus, where peristaltic contractions move the bolus toward the stomach. The lower esophageal sphincter relaxes to allow the bolus to enter the stomach and then closes to prevent reflux (backward flow) of stomach contents.

◆ See Chapter 3 for a complete review of the GI tract and its functions; common digestive problems and simple self-help measures were introduced in Highlight 3.

Conditions Affecting the Esophagus

Disorders of the esophagus may be accompanied by difficulty with swallowing, a sensation of something "stuck in the throat," or pain in the chest area. This section examines the causes and treatments of the two most common problems affecting the esophagus. Dysphagia (difficulty swallowing), introduced in Chapter 18, is discussed in more detail here. Gastroesophageal reflux disease, often referred to as "heartburn," was introduced and defined in Highlight 3.

Dysphagia

The act of swallowing involves multiple processes. In the initial, or **oropharyngeal,** phase of swallowing, muscles in the mouth and tongue propel the bolus of

oropharyngeal (OR-oh-fah-ren-JEE-al): involving the mouth and pharynx.

FIGURE 23-1 The Upper GI Tract

Mouth
Chews and mixes food with saliva.

Pharynx
Directs food from mouth to esophagus.

Epiglottis
Protects airway during swallowing.

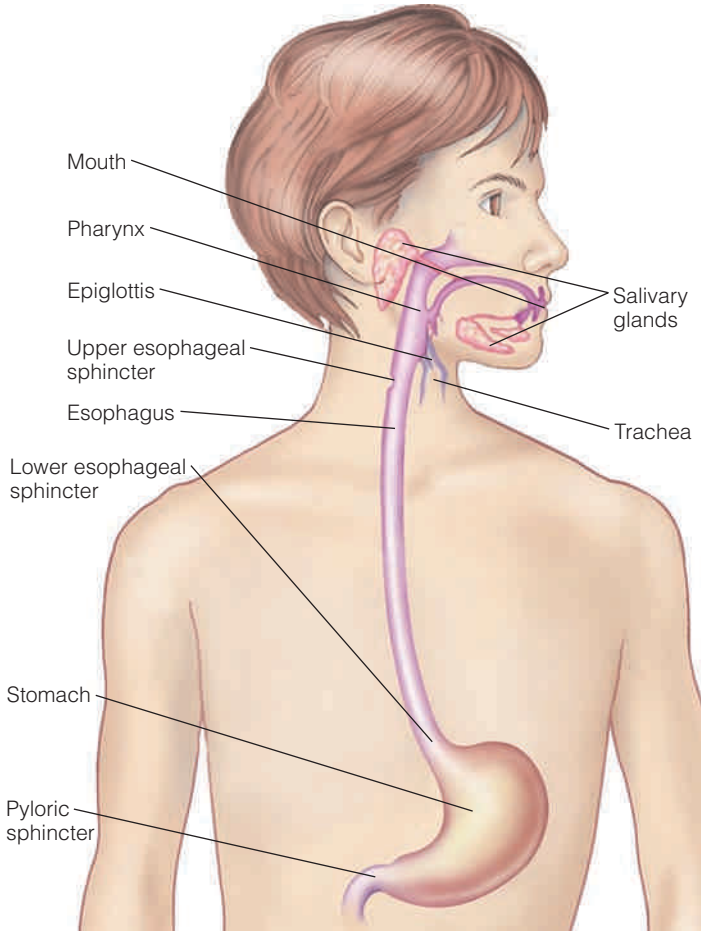
Upper esophageal sphincter
Allows passage from mouth to esophagus. Prevents backflow from esophagus.

Esophagus
Conducts food to stomach.

Lower esophageal sphincter
Allows passage from esophagus to stomach. Prevents backflow from stomach.

Stomach
Adds acid, enzymes, and fluid. Churns, mixes, and grinds food to a liquid mass.

Pyloric sphincter
Allows passage from stomach to small intestine. Prevents backflow from small intestine.



Salivary glands
Secrete saliva (provides moisture and contains starch-digesting enzymes).

Trachea
Allows air to pass to and from lungs.

food through the pharynx and into the esophagus. At the same time, tissues of the soft palate prevent food from entering the nasal passages, and the epiglottis blocks the opening to the trachea to prevent aspiration of food substances or saliva into the lungs. In the second, or **esophageal,** phase of swallowing, peristalsis forces the bolus through the esophagus, and the lower esophageal sphincter relaxes to allow passage of the bolus into the stomach. Due to the many tasks involved in swallowing, dysphagia can result from a number of different physical or neurological conditions. Table 23-1 lists some potential causes of dysphagia, which are categorized according to the phase of swallowing that is impaired.[1]

esophageal (eh-SOF-ah-JEE-al): involving the esophagus.

oropharyngeal dysphagia: an inability to transfer food from the mouth and pharynx to the esophagus; usually caused by a neurological or muscular disorder.

esophageal dysphagia: an inability to move food through the esophagus; usually caused by an obstruction or a motility disorder.

stricture: abnormal narrowing of a passageway; often due to inflammation, scarring, or a congenital abnormality.

Oropharyngeal Dysphagia A person with **oropharyngeal dysphagia** typically has a neuromuscular condition that upsets the swallowing reflex or impairs the necessary movements of the tongue and other oral tissues. Symptoms include an inability to initiate swallowing, coughing during or after swallowing (due to aspiration), and nasal regurgitation. Other signs include bad breath, a gurgling noise after swallowing, a hoarse or "wet" voice, or a speech disorder. Oropharyngeal dysphagia occurs frequently in elderly people and is often caused by stroke.[2]

Esophageal Dysphagia A person with **esophageal dysphagia** usually has an obstruction in the esophagus or a motility disorder; the main symptom is often the sensation of food "sticking" in the esophagus after it is swallowed. An obstruction can be caused by a **stricture** (abnormal narrowing), tumor, or compression of the esoph-

agus by surrounding tissues. Whereas an obstruction may affect the passage of solid foods only and may not affect liquids, a motility disorder hinders the passage of both solids and liquids. **Achalasia,** the most common motility disorder, is a degenerative nerve condition affecting the esophagus; it is characterized by impaired peristalsis and incomplete relaxation of the lower esophageal sphincter when swallowing.[3]

Complications of Dysphagia Health practitioners should be alert to the various complications that can indicate a dysphagia problem. If food consumption is reduced due to dysphagia, malnutrition and weight loss may occur. Individuals who cannot swallow liquids are at increased risk of dehydration. A serious and potentially life-threatening complication associated with dysphagia is aspiration, which may cause airway obstruction, choking, or respiratory infections, including pneumonia. If a person does not have a normal cough reflex, aspiration is more difficult to diagnose and may go unnoticed.

Evaluation of Dysphagia Although the signs and symptoms of dysphagia can help a health care provider recognize the condition, diagnosing the exact cause generally requires further examination. A barium swallow study often reveals the nature of the problem. In this procedure, the patient consumes foods or liquids that contain barium (a metallic element visible on X-rays), and the swallowing process is monitored using a video X-ray technique known as videofluoroscopy. Another assessment method, endoscopy, uses a thin, flexible tube to examine the esophageal lumen directly. Peristalsis and sphincter pressure can be measured using a manometer, a flexible catheter containing multiple pressure sensors that is passed into the esophagus. A neurological examination may be needed to evaluate mental status, physical reflexes, and the cranial nerves associated with swallowing.

Nutrition Intervention for Dysphagia Modifying the physical properties of foods and beverages and using alternative feeding methods can help to compensate for swallowing difficulties. Because a wide variety of defects can cause dysphagia, finding the best diet is often a challenge. Even after careful assessment of a person's swallowing abilities, the most appropriate foods may be determined only by trial and error. A person's swallowing abilities may fluctuate over time, so the dietary plan needs frequent reassessment.

The National Dysphagia Diet, developed in 2002 by a panel of dietitians, speech and language therapists, and a food scientist, has helped to standardize the nutrition care of dysphagia patients.[4] Table 23-2 on p. 734 presents brief descriptions of the different levels of the diet and some sample meals.[5] After the appropriate dietary level is selected, it must be adjusted to suit the person's swallowing abilities and tolerances. A consultation with a swallowing expert, such as a speech and language therapist, is often necessary.

Food Properties and Preparation Foods included in dysphagia diets should have easy-to-manage textures and consistencies. Soft, cohesive foods are easier to handle than hard or crumbly foods. Moist foods are better tolerated than dry foods. Some foods within a category may be acceptable and others may not; for example, some cookies are soft and tender, whereas others are hard and brittle. Sticky or gummy foods, such as peanut butter and cream cheese, may be difficult to clear from the mouth and throat.

The textures of foods can be altered to make them easier to swallow. Foods are often pureed, mashed, ground, or minced (review Table 18-5 on p. 623). Foods that have more than one texture, such as vegetable soup or cereal with milk, are harder to handle, so ingredients may be blended to a single consistency and items such as nuts and seeds omitted.

Consuming foods that have a similar consistency can quickly become monotonous. By using commercial thickeners and food molds, pureed foods can be formed into attractive shapes. Including a variety of flavors and colors can also make a meal more appealing. The "How to" on p. 735 offers additional suggestions that can improve the acceptance of pureed and other mechanically altered foods.

TABLE 23-1 Causes of Dysphagia

Oropharyngeal Dysphagia

- Alzheimer's disease (advanced stages)
- Developmental disabilities
- Goiter
- Lou Gehrig's disease (amyotrophic lateral sclerosis)
- Multiple sclerosis
- Muscular dystrophy
- Myasthenia gravis
- Parkinson's disease
- Poliomyelitis
- Stroke

Esophageal Dysphagia

- Achalasia
- Enlarged atrium (right side of heart)
- Esophageal cancer
- Esophageal spasm
- Scleroderma
- Strictures (from inflammation, scarring, or a congenital abnormality)
- Thoracic tumor (usually lung cancer)

Courtesy Diamond Crystal Specialty Foods

Can you tell that the foods in this photo are pureed foods shaped with food molds?

achalasia (ack-ah-LAY-zhah): an esophageal disorder characterized by weakened peristalsis and impaired relaxation of the lower esophageal sphincter.
- **a** = without
- **chalasia** = relaxation

TABLE 23-2 National Dysphagia Diet

Level 1: Dysphagia Pureed

Foods should be pureed or well mashed, homogeneous, and cohesive. This diet is for patients with moderate to severe dysphagia and poor oral or chewing ability.

Sample menus:

- *Breakfast:* Cream of wheat, slurried muffins or pancakes,[a] pureed scrambled eggs, mashed bananas, fruit juice without pulp (thickened as needed), coffee or tea (if thin liquids are acceptable).
- *Lunch or dinner:* Pureed tomato soup, slurried crackers, pureed meat or poultry, broccoli soufflé, mashed potatoes with gravy, pureed carrots or green beans, smooth applesauce, pureed peaches, chocolate pudding.

  Foods to avoid: Cheese (including cottage cheese), oatmeal, rice, peanut butter, fruit preserves with chunks or seeds, chunky applesauce, beverages with pulp, coarsely ground pepper, herbs.

Level 2: Dysphagia Mechanically Altered

Foods should be moist, cohesive, and soft textured and should easily form a bolus. This diet is for patients with mild to moderate dysphagia; some chewing ability is required.

Sample menus:

- *Breakfast:* Moist oatmeal, cornflakes or puffed rice cereal with milk (thickened as needed), moist pancakes or muffins (with butter, margarine, or jam), soft scrambled eggs, cottage cheese, ripe bananas or cooked fruit without skin or seeds, fruit juice (thickened as needed), coffee or tea (if thin liquids are allowed).
- *Lunch or dinner:* Soup with easy-to-chew meat and vegetables; slurried bread or crackers; minced, tender-cooked meat; well-cooked pasta with moist meatballs and meat sauce; baked potato with gravy; soft, tender-cooked vegetables (not fibrous or rubbery); canned peach slices; soft fruit pie (with bottom crust only); soft, smooth chocolate bar.

  Foods to avoid: Dry foods, frankfurters, sausage, hard-cooked eggs, corn and clam chowders; sandwiches, pizza, sliced cheese, rice, potato skins, French fries, corn, broccoli, asparagus, brussels sprouts, cabbage, peanut butter, coconut, nuts and seeds, fruit with skin or seeds, canned pineapple, dried fruit, chewy candies (such as caramel or licorice).

Level 3: Dysphagia Advanced

Foods should be moist and be in bite-sized pieces when swallowed; foods with mixed textures are included. This diet is for patients with mild dysphagia and adequate chewing ability.

Sample menus:

- *Breakfast:* Cereal with milk, moist pancakes or muffins (with butter, margarine, or jam), poached or scrambled eggs, cheese, soft fresh fruit (peeled) or berries, coffee or tea (if thin liquids are tolerated).
- *Lunch or dinner:* Chicken noodle soup; moistened crackers or bread; thin-sliced tender meat; moist, soft-cooked potatoes or rice; tender-cooked vegetables; shredded lettuce with dressing; fresh peach or melon; canned fruit salad; moist chocolate chip cookie (without nuts).

  Foods to avoid: Dry foods; corn and clam chowders; potato skins; corn; raw vegetables; chunky peanut butter; coconut; nuts and seeds; hard fruit (such as apples or pears); fruit with skin, seeds, or stringy textures (such as mango or pineapple); uncooked dried fruit; fruit leathers; popcorn; chewy candies (such as caramel or licorice).

Liquid Consistencies (only those tolerated are allowed in the diet)

- *Thin:* Watery fluids; may include milk, coffee, tea, juices, carbonated beverages.
- *Nectarlike:* Fluids thicker than water that can be sipped through a straw; may include buttermilk, eggnog, tomato juice.
- *Honeylike:* Fluids that can be eaten with a spoon but do not hold their shape; may include honey, tomato sauce, yogurt.
- *Spoon-thick:* Thick fluids that must be eaten with a spoon and can hold their shape; may include milk pudding, thickened applesauce.

[a] Slurried foods are mixed with liquid until the consistency is appropriate; they may be gelled and shaped to improve appearance.
SOURCE: American Dietetic Association, *Nutrition Care Manual* (Chicago: American Dietetic Association, 2007).

Properties of Liquids Thickened liquids are easier to swallow than thin liquids such as water or juice. Table 23-2 describes the four levels of liquid consistencies prescribed for dysphagia patients, referred to as thin, nectarlike, honeylike, and spoon-thick. To increase liquid viscosity, commercial starch thickeners are stirred into beverages and other liquid foods, such as soup broths. Some beverages can lose their appeal when thickened; for example, individuals may find thickened coffee and tea unacceptable. Furthermore, hydration is more difficult to maintain when a patient has access to only thickened beverages, which are less acceptable for quenching thirst.

Feeding Strategies for Dysphagia Depending on the nature of the swallowing problem, some patients can learn new feeding techniques to help them compensate for their disability. For example, people with oropharyngeal dysphagia can do exercises that strengthen the jaws, tongue, or larynx or learn new methods of swallowing that allow them to consume a normal diet. Changing the position of the head and neck while eating can also minimize some swallowing problems. Speech and language therapists are often responsible for teaching patients these techniques.

Gastroesophageal Reflux Disease

◆ Highlight 3 introduced gastroesophageal reflux disease and discussed strategies for preventing its recurrence.

Gastroesophageal reflux disease (GERD) ◆ is a condition of gastric reflux that causes frequent discomfort and, sometimes, tissue damage. Reflux of the stomach's acidic contents can irritate the esophagus, and small amounts may enter the mouth. Peo-

HOW TO Improve Acceptance of Mechanically Altered Foods

Take a moment to think about a meal of pureed or ground foods. A typical dinner of baked chicken, potatoes, carrots, and green beans can look like mounds of differently colored mush. The foods may taste great, but a person may have little appetite before trying a first bite. To improve appetite, be creative when preparing and serving meals:

- Help to stimulate the appetite by preparing favorite foods and foods with pleasant smells. Enliven food flavors with seasonings and spices.
- Use attractive plates and silverware to improve the visual appeal of a meal. Consider colors and shapes when arranging foods on a plate; colorful garnishes can add color and eye appeal. Substitute brightly colored vegetables for white vegetables; for example, replace mashed potatoes with mashed sweet potatoes.
- Try layering ingredients so that the entrée looks like a fancy casserole. For example, recipes can resemble such popular entrées as lasagna, shepherd's pie, and moussaka.
- Shape pureed and ground foods to resemble traditional dishes. Flatten a spoonful of pureed meat to make a patty, or use small scoops so that meat resembles meatballs. Use food molds to restore slurried breads and pureed meats to their traditional shapes.

Efforts to improve the visual appearance of foods can go a long way toward helping people eat nourishing meals and maintain a healthy weight.

ple who suffer from GERD often refer to these symptoms as *heartburn* or *acid indigestion*. Reflux does not necessarily cause symptoms or injury—it occurs occasionally in healthy people and is a problem only if it creates complications and requires lifestyle changes or medical treatment.

Causes of GERD The lower esophageal sphincter is the main barrier to gastric reflux, so GERD can result if the sphincter muscle is weak or relaxes inappropriately. Medical conditions that interfere with the sphincter's mechanism or prevent rapid clearance of acid from the esophagus can also predispose a person to GERD.

Conditions associated with high rates of GERD include pregnancy, asthma, and **hiatal hernia,** a condition in which a portion of the stomach protrudes above the diaphragm (see Figure 23-2 on p. 736). Pregnancy is the most common predisposing condition; as many as two-thirds of pregnant women report heartburn, which often begins in the first trimester.[6] Some medications may increase the risk of reflux, as does the use of nasogastric tubes in tube feedings. Various other conditions and substances can exacerbate GERD by either weakening the sphincter or raising pressure within the stomach; Table 23-3 on p. 736 lists examples.

Consequences of GERD If gastric acid remains in the esophagus long enough to damage the esophageal lining, the resulting inflammation is called **reflux esophagitis.** Severe and chronic inflammation may lead to esophageal ulcers, with consequent bleeding. Healing and scarring of ulcerated tissue may narrow the inner diameter of the esophagus, causing esophageal stricture. A slowly progressive dysphagia for solid foods sometimes results, and swallowing occasionally becomes painful. Pulmonary disease may develop if gastric contents are aspirated into the lungs. Chronic reflux is also associated with **Barrett's esophagus,** a condition in which damaged esophageal cells are gradually replaced by cells that resemble those in gastric or intestinal tissue; such cellular changes increase the risk of developing esophageal cancer. GERD can also damage tissues in the mouth, pharynx, and larynx, resulting in eroded tooth enamel, sore throat, and laryngitis.[7]

Treatment of GERD Treatment objectives are to alleviate symptoms and facilitate the healing of damaged tissue. Severe ulcerative disease may require immediate acid-suppressing medication, whereas a mild case may be managed with dietary and lifestyle modifications. The "How to" on p. 737 offers suggestions that may help to prevent the recurrence of gastrointestinal reflux.

Medications that suppress gastric acid secretion help the healing process by reducing the damaging effects of acid on esophageal tissue. **Proton-pump inhibitors** are the most effective of the antisecretory agents and are used both for

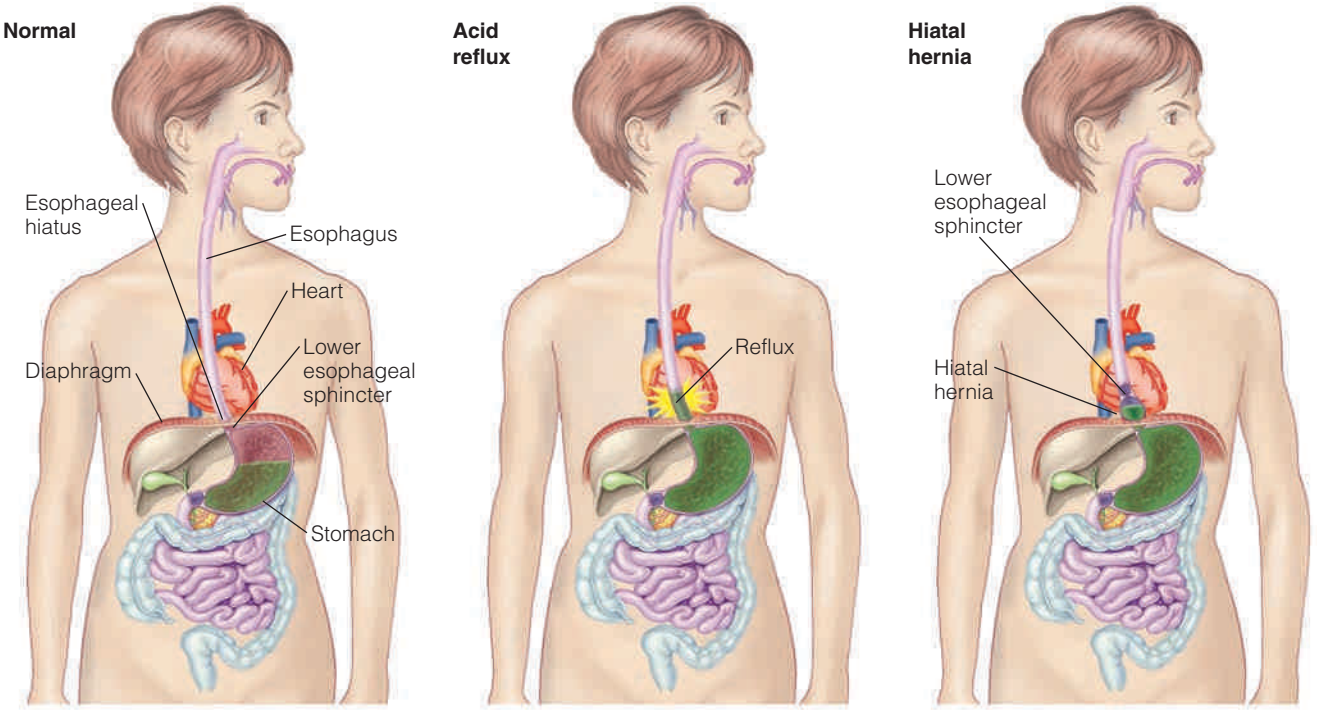
hiatal hernia: a condition in which the upper portion of the stomach protrudes above the diaphragm; most cases are asymptomatic.

reflux esophagitis: inflammation in the esophagus related to the reflux of acidic stomach contents.

Barrett's esophagus: a condition in which esophageal cells damaged by chronic exposure to stomach acid are replaced by cells that resemble those in the stomach or small intestine, sometimes becoming cancerous.

proton-pump inhibitors: a class of drugs that inhibit the enzyme that pumps hydrogen ions (protons) into the stomach. Examples include omeprazole (Prilosec) and lansoprazole (Prevacid).

FIGURE 23-2 The Upper GI Tract, Acid Reflux, and Hiatal Hernia



The stomach normally lies below the diaphragm, and the esophagus passes through the esophageal hiatus. The lower esophageal sphincter prevents reflux of stomach contents.

Whenever the pressure in the stomach exceeds the pressure in the esophagus, as can occur with overeating and overdrinking, the chance of reflux increases. The resulting "heartburn" is so named because it is felt in the area of the heart.

Risk of acid reflux may increase as a consequence of a hiatal hernia. A "sliding" hiatal hernia occurs when part of the stomach, along with the lower esophageal sphincter, rises above the diaphragm.

rapid healing of esophagitis and as a maintenance treatment. Other drugs used for GERD include **histamine-2 receptor blockers** (often referred to as *H2 blockers*) and antacids, which neutralize gastric acid. Although antacids are frequently used to relieve occasional heartburn, they are not necessarily appropriate for GERD be-

histamine-2 receptor blockers: a class of drugs that suppress acid secretion by inhibiting receptors on acid-producing cells; commonly called **H2 blockers.** Examples include cimetidine (Tagamet), ranitidine (Zantac), and famotidine (Pepcid).

TABLE 23-3 Conditions and Substances Associated with Esophageal Reflux

Conditions That Raise the Likelihood of Reflux	Substances That Weaken Lower Esophageal Sphincter Pressure
Ascites (accumulation of fluid in the abdomen)	Alcohol
Delayed gastric emptying	Anticholinergic agents
Eating large meals	Antihistamines
Lying flat after eating	Caffeine
Obesity	Calcium channel blockers
Pregnancy	Chocolate
Wearing clothes that fit tightly across the waist or abdomen	Cigarette smoking
	Diazepam
	Garlic
	High-fat foods
	Onions
	Peppermint and spearmint oils
	Progesterone
	Theophylline
	Tricyclic antidepressants

HOW TO Manage Gastrointestinal Reflux Disease

Management of GERD often requires lifestyle changes to help minimize discomfort and reduce recurrence of acid reflux. Recommendations generally include the following:

- Avoid eating bedtime snacks or lying down after meals. Meals should be consumed at least two to three hours before bedtime.
- Reduce nighttime reflux by elevating the head of the bed on 6-inch blocks, inserting a foam wedge under the mattress, or propping pillows under the head and upper torso.
- Consume only small meals, and drink liquids between meals so that the stomach does not become overly distended, which can exert pressure on the lower esophageal sphincter.
- Limit foods that weaken lower esophageal sphincter pressure or increase gastric acid secretion; these include chocolate, fatty foods, spearmint and peppermint, coffee (both caffeinated and decaffeinated), and tea.
- Avoid cigarettes and alcohol; both relax the lower esophageal sphincter.
- Avoid bending over and wearing tight-fitting garments; both can cause pressure in the stomach to increase, heightening the risk of reflux.
- Advise obese individuals to lose weight if they are adequately motivated. Obesity can increase abdominal pressure.
- During periods of esophagitis, avoid foods and beverages that may irritate the esophagus, such as citrus fruits and juices, tomato products, pepper, spicy foods, carbonated beverages, and very hot or very cold foods (depending on individual tolerances).
- Avoid using nonsteroidal anti-inflammatory drugs (NSAIDs) such as aspirin, naproxen, and ibuprofen, which can damage the esophageal mucosa.

Food tolerances among people with GERD can vary markedly. Health professionals can help patients pinpoint food intolerances by advising them to keep a record of the foods and beverages consumed, as well as any resulting symptoms.

cause they have only short-term effects, are associated with gastrointestinal side effects, and may cause some nutrient deficiencies when used over the long term.

Surgery may be required in severe cases of GERD that are unresponsive to medications and lifestyle changes. In one popular procedure (called *fundoplication*), the upper section of the stomach (the fundus) is gathered up around the esophagus and sewn in such a way that the esophagus and sphincter are surrounded by stomach muscle, which increases pressure within the esophagus and fortifies the sphincter muscle. Esophageal strictures are often treated by dilating the esophagus (with an inflatable balloon-like device or a fixed-size dilator) or by using surgical approaches. The Case Study below includes questions that review the usual treatments for a patient with GERD.

CASE STUDY Accountant with GERD

Gina Rinaldi is a 49-year-old accountant who is 5 feet 4 inches tall and weighs 165 pounds. She recently underwent a complete physical examination. She told her physician that she had been feeling fairly well until she began experiencing heartburn, which has progressively become more frequent and painful. The heartburn often occurs after she eats a large meal and is particularly bad after she goes to bed at night. By directly examining the esophageal lumen using an endoscope (a thin, flexible tube equipped with an optical device), the physician found evidence of reflux esophagitis and a slight narrowing throughout the length of the esophagus.

Mrs. Rinaldi's medical history does not indicate any significant health problems. During her last physical exam, her physician advised her to stop smoking cigarettes and to lose 20 pounds, but she has not attempted to do either. The nutrition assessment reveals that Mrs. Rinaldi is feeling stressed because it is the middle of the tax season. She usually has little time for breakfast, eats a lunch of fast foods while continuing to work at her desk, and eats a large dinner at around 8:00 P.M. She generally has wine with dinner and another alcoholic beverage later in the evening.

1. Explain to Mrs. Rinaldi the meaning of the medical diagnoses *reflux esophagitis* and *esophageal stricture.*
2. From the brief history provided, list the factors and behaviors that increase Mrs. Rinaldi's risks of experiencing reflux. What recommendations can you make to help her change these behaviors?
3. What medications might the physician prescribe, and why?

IN SUMMARY

Dysphagia and gastroesophageal reflux are the most common esophageal disorders. Dysphagia can interfere with food intake and increase the risk of aspiration. Treatment may include dietary adjustments, strengthening exercises, and using different swallowing techniques. Gastroesophageal reflux disease (GERD) may lead to esophageal ulcers, inflammation, bleeding, and stricture. Treatment includes the use of acid-suppressing drugs and lifestyle changes.

Conditions Affecting the Stomach

Stomach disorders range from occasional bouts of discomfort to severe conditions that require surgery. This section begins with a discussion of **dyspepsia** (often called "indigestion"), the sensation of pain or discomfort in the upper abdomen that occurs after food consumption. More serious stomach conditions that may benefit from dietary adjustments include **gastritis** and **peptic ulcers,** which most often result from bacterial infection or from the use of medications that damage the stomach lining.

Dyspepsia

Dyspepsia refers to the general symptoms of indigestion in the upper abdominal region, which may include stomach pain, gnawing sensations, early satiety, nausea, vomiting, and bloating. These symptoms sometimes indicate the presence of more serious illnesses, such as GERD or peptic ulcer disease. Although about 25 percent of the population experiences dyspepsia, only one person in four seeks medical attention.[8]

Causes of Dyspepsia Abdominal symptoms don't always lead to a clear diagnosis, as the cause of the symptoms can be difficult to identify. Various medical conditions can cause abdominal discomfort; they include peptic ulcers, GERD, motility disorders, malabsorptive disorders (discussed in Chapter 24), gallbladder disease, and tumors in the esophagus or stomach. Chronic diseases such as diabetes mellitus, heart disease, and hypothyroidism can sometimes be accompanied by gastric symptoms. Some medications, including aspirin (and other nonsteroidal anti-inflammatory drugs), antibiotics, digitalis, and theophylline, can cause gastrointestinal distress. Dietary supplements may also be a cause; for example, iron and potassium supplements and some herbal products can cause gastrointestinal problems. Intestinal conditions such as irritable bowel syndrome or lactose intolerance may mimic dyspepsia. Although pinpointing the cause of the symptoms can be difficult, a complete examination is in order if the individual experiences weight loss, persistent vomiting, dysphagia, anemia, or bleeding, which suggest the presence of serious illness.[9]

dyspepsia: a feeling of pain, bloating, or discomfort in the upper abdominal area, often called **indigestion;** a symptom of illness rather than a disease itself.
- **dys** = bad; impaired
- **pepsia** = refers to digestion

gastritis: inflammation of stomach tissue.

peptic ulcers: ulcers in the gastrointestinal mucosa resulting from exposure to gastric secretions; may develop in the esophagus, stomach, or duodenum.
- **peptic** = related to digestion

Potential Food Intolerances Although many people attribute their symptoms to eating certain foods or spices, controlled studies have been unable to find associations between specific foods and dyspepsia. Coffee can induce symptoms in about 50 percent of dyspepsia patients, however, and also increases gastric acid production and acid reflux.[10] Spicy foods may cause some injury to the mucosal lining and exacerbate the pain from a preexisting ulcer. High-fat meals can slow gastric emptying and thereby exacerbate dyspepsia. To minimize symptoms, people with dyspepsia are sometimes advised to consume small meals with well-cooked foods that are not overly seasoned and to consume meals in a relaxed atmosphere.[11]

Bloating and Stomach Gas The feeling of bloating may be caused by excessive gas in the stomach, which accumulates when air is swallowed. Swallowing air often

accompanies gum chewing, smoking, rapid eating, drinking carbonated beverages, and using a straw. Omitting these practices generally helps to correct the problem.

Nausea and Vomiting

Nausea and vomiting accompany many illnesses and are common side effects of medications. Although occasional vomiting is not dangerous, prolonged vomiting can cause fluid and electrolyte imbalances and may require medical care. Chronic vomiting can reduce food intake and lead to malnutrition and nutrient deficiencies.

The timing of vomiting gives clues about its cause. Vomiting that occurs within an hour after a meal suggests a peptic ulcer or a psychological cause. If it occurs more than one hour after a meal, possible causes include food poisoning, an obstruction that prevents stomach emptying, or a stomach motility disorder.

Treatment of Nausea and Vomiting The main goal of treatment is to find and correct the underlying disorder. Most cases are short-lived and require no treatment. Restoring hydration may be necessary. If a medication is the cause, taking it with food may help. If the cause is unknown or the underlying disorder cannot be corrected, medications that suppress nausea and vomiting can be prescribed. People with **intractable vomiting**—vomiting that is not easily controlled—may require intravenous nutrition support.

Dietary Interventions Sometimes nausea can be prevented or improved with dietary measures. Eating and drinking slowly may be helpful, as may eating small meals that do not distend the stomach. Drinking clear, cold beverages such as carbonated drinks or fruit juices may ease symptoms. Foods that may help to reduce nausea include dry, salty foods like crackers or pretzels. Fried or spicy foods and foods with strong odors should be avoided. Foods that are cold or at room temperature may be better tolerated than hot meals. Individuals sometimes have strong food aversions when nauseated, and tolerances vary greatly.

TABLE 23-4 Potential Causes of Gastritis

Infection
- Bacterial: *Helicobacter pylori, Actinomyces israelii*
- Fungal: *Candida albicans*
- Parasitic: Cryptosporidiosis, nematode infection
- Viral: Cytomegalovirus

Chemical Substances
- Alcohol
- Cocaine
- Drugs (especially aspirin and other NSAIDs)
- Ingestion of corrosive materials

Internal (bodily) Causes
- Autoimmune
- Bile reflux
- Stress
- Systemic illness/sepsis

Miscellaneous
- Food sensitivity (allergy)
- Foreign bodies
- High salt intake
- Radiation therapy

Gastritis

Gastritis is a general term that refers to inflammation of the stomach mucosa. ◆ As shown in Table 23-4, gastritis can result from infection, chemical substances, and diseases and treatments that damage the stomach lining. Most often, gastritis results from ***Helicobacter pylori*** infection or the use of nonsteroidal anti-inflammatory drugs (NSAIDs), both primary causes of peptic ulcer disease as well.

◆ The suffix *-itis* refers to the presence of inflammation in an organ or tissue.

If the gastric mucosa shows signs of tissue destruction, ulcers, or hemorrhaging (severe bleeding), the condition may be called **erosive gastritis,** even if inflammation is not present.[12] Erosive gastritis can be caused by substances or treatments that irritate the gastric mucosa, including alcohol and other chemical substances, viral infection, radiation treatment, and bile reflux. Gastritis that becomes chronic and is associated with tissue destruction is known as *atrophic gastritis;* ◆ it is especially prevalent among adults over 60 years of age.

◆ Reminder: Atrophic gastritis was introduced in Chapter 10 (p. 343).

Complications of Gastritis The extensive tissue damage that sometimes develops in chronic gastritis can disrupt gastric secretory functions. If hydrochloric acid secretions become abnormally low **(hypochlorhydria)** or absent **(achlorhydria),** absorption of nonheme iron and vitamin B_{12} can be impaired, and the risk of deficiency increases. Pernicious anemia, a condition characterized by the destruction of stomach cells that produce intrinsic factor, is a late complication of atrophic gastritis and a primary cause of vitamin B_{12} deficiency (see p. 343).

Dietary Interventions for Gastritis Dietary recommendations depend on an individual's symptoms. If gastritis is asymptomatic, no dietary adjustments are needed. If pain or discomfort is present, the patient should avoid irritating foods and beverages; these usually include alcohol, coffee (including decaffeinated), tea, cola beverages, spicy foods, and fatty or greasy foods. If food consumption increases pain or

intractable vomiting: vomiting that is not easily managed or controlled.

Helicobacter pylori: a species of bacterium that colonizes gastric mucosa; a primary cause of gastritis and peptic ulcer disease.

erosive gastritis: erosion of the gastric mucosa, characterized by tissue destruction, ulcers, and hemorrhaging; often caused by the toxic effects of chemical substances or radiation treatment.

hypochlorhydria (HIGH-poe-clor-HIGH-dree-ah): a reduction in gastric acid secretion.

achlorhydria (AY-clor-HIGH-dree-ah): absence of gastric acid secretion.

causes nausea and vomiting, food intake should be avoided for 24 to 48 hours to rest the stomach. Nutrition support may be necessary if the patient cannot tolerate food for a prolonged period. If gastritis results in hypochlorhydria or achlorhydria, supplementation of iron and vitamin B_{12} may be warranted.

Peptic Ulcer Disease

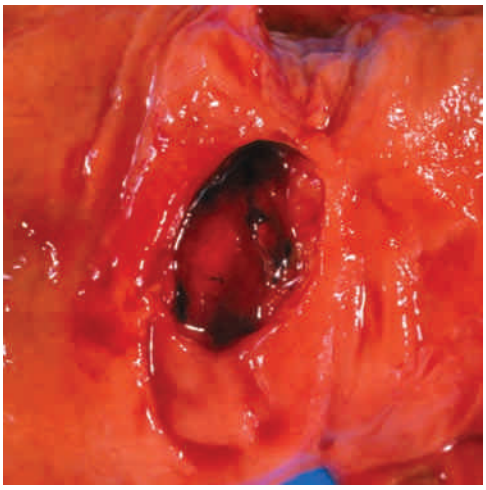
A **peptic ulcer** is an ulceration that develops in the gastrointestinal mucosa when gastric acid and pepsin overwhelm mucosal defenses and destroy mucosal tissue. A primary factor in peptic ulcer development is *Helicobacter pylori* infection, which is present in about 80 percent of patients with duodenal ulcers and 60 percent of those with gastric ulcers.[13] ◆ Another major factor is the use of NSAIDs, which have both topical and systemic effects that can damage mucosal tissue. In rare cases, ulcers may develop from disorders that cause excessive acid secretion: one such condition is **Zollinger-Ellison syndrome,** characterized by the presence of gastrin-secreting tumors in the duodenum or pancreas. ◆ Ulcer risk can be increased by cigarette smoking, psychological stress, and genetic factors.[14]

◆ The specific reasons why ulcers develop are not known; only 10 to 15 percent of individuals with chronic *Helicobacter pylori* infection actually develop a peptic ulcer.

◆ Reminder: *Gastrin* is a hormone that signals stomach cells to secrete hydrochloric acid.

Effects of Emotional Stress Although most ulcers are associated with *H. pylori* infection or NSAID use, about a quarter of ulcers develop in people for other reasons.[15] Emotional stress is not believed to cause ulcers per se, but it has effects on physiological processes and behaviors that may increase a person's vulnerability. Physiological effects of stress vary among individuals but may include rapid stomach emptying (which increases the acid load in the duodenum), hormonal changes that impair wound healing, and increases in acid and pepsin secretions. Stress may also lead to behavioral changes, including increased use of cigarettes, alcohol, and NSAIDs—all potential risk factors for ulcers. Thus, stress may play a contributory role in ulcer development, although its precise effects are not fully understood.

Symptoms of Peptic Ulcers Peptic ulcer symptoms vary. Some people are asymptomatic or experience only mild discomfort. Ulcer "pain" may be experienced as a hunger pain, a sensation of gnawing, or a burning pain in the stomach region. The pain or discomfort of ulcers may be relieved by food and recur several hours after a meal, especially if the ulcer is duodenal. Gastric ulcers may be aggravated by food and can cause loss of appetite and eventual weight loss. ◆ Ulcer symptoms tend to go into remission regularly and recur every few weeks or months.[16]



© Dr. E. Walker/Photo Researchers, Inc.

A peptic ulcer, such as the gastric ulcer shown here, damages mucosal tissue and may cause pain and bleeding.

Complications of Peptic Ulcers Peptic ulcers are a major cause of gastrointestinal bleeding, which occurs in about 15 to 20 percent of ulcer cases.[17] Bleeding is a potential cause of death and, if severe, may indicate the need for surgical intervention. Severe bleeding is evidenced by black, tarry stool samples or, occasionally, vomit that resembles coffee grounds. Other serious complications of ulcers include perforations of the stomach or duodenum (sometimes leading directly into the peritoneal cavity) and gastric outlet obstruction due to scarring or inflammation.

◆ In the United States, most ulcers are duodenal ulcers. In Asian countries, gastric ulcers are more common.

Drug Therapy for Peptic Ulcers The goals of ulcer treatment are to relieve pain, promote healing, and prevent recurrence. In most cases, treatment requires using a combination of antibiotics to eradicate *H. pylori* infection and/or discontinuing the use of aspirin and other NSAIDs, which can irritate the gastric mucosa and delay healing. Antisecretory and acid-neutralizing drugs may be prescribed to relieve pain and allow healing; these include proton-pump inhibitors, H2 blockers, and antacids (as used in GERD; see the earlier discussion on pp. 735–737). Bismuth preparations (such as Pepto-Bismol) or sucralfate may help by coating the gastrointestinal lining and preventing further tissue erosion. The most frequently prescribed drug regimen is a "triple therapy" that includes two antibiotics and one other type of drug; the antibiotics used to treat *H. pylori* infection include amoxicillin, clarithromycin, metronidazole, and tetracycline.[18] See the Diet-Drug Interactions feature for nutrition-related effects of the medications used in ulcer treatment.

peptic ulcer: an erosion in the gastrointestinal mucosa resulting from the destructive effects of gastric acid and pepsin.

Zollinger-Ellison syndrome: a condition characterized by the presence of gastrin-secreting tumors in the duodenum or pancreas.

DIET-DRUG INTERACTIONS

Check this table for notable nutrition-related effects of the medications discussed in this chapter.

	Gastrointestinal Effects	Interactions with Dietary Substances	Metabolic Effects
Antacids (aluminum hydroxide, magnesium hydroxide, calcium carbonate)	Constipation (aluminum- or calcium-containing antacids), diarrhea (magnesium-containing antacids).	May decrease iron, folate, or vitamin B_{12} absorption.	Hypophosphatemia (from excess aluminum, magnesium, or calcium).
Antibiotics (for *Helicobacter pylori* infection; may include amoxicillin, metronidazole, tetracycline)	Diarrhea (amoxicillin, tetracycline), nausea and vomiting (tetracycline), altered taste sensation (metronidazole).	Avoid alcohol with metronidazole; tetracycline decreases iron absorption and binds calcium in the GI tract, reducing absorption of both the tetracycline and the calcium.	—
Antisecretory agents (proton-pump inhibitors, H2 blockers)	Constipation, nausea and vomiting, abdominal pain (proton-pump inhibitors).	May decrease iron, folate, and vitamin B_{12} absorption.	—
Coating agents (bismuth preparations, sucralfate)	Constipation, diarrhea.	—	Hypophosphatemia, calcium retention (sucralfate).

Nutrition Care for Peptic Ulcers The goals of nutrition care are to correct nutrient deficiencies, if necessary, and encourage dietary and lifestyle practices that minimize symptoms.[19] Patients should avoid dietary items that increase acid secretion or irritate the gastrointestinal lining; examples include alcohol, coffee and other caffeine-containing beverages, chocolate, and pepper, although individual tolerances vary. Small meals may be better tolerated than large ones. Patients should avoid food consumption for at least two hours before bedtime. Cigarette smoking should be discouraged, as it can delay healing and increase the risk of ulcer recurrence.[20] There is no evidence that dietary adjustments can alter the rate of healing.[21]

IN SUMMARY

Dyspepsia refers to general symptoms of indigestion such as abdominal pain, nausea, and vomiting, which are caused by many different medical conditions. Gastritis and peptic ulcer disease are most often associated with *Helicobacter pylori* infection, which can be eradicated by antibiotic therapy. In addition, NSAID use can promote gastritis and peptic ulcer disease by damaging the mucosal lining. Extensive damage to the mucosa may reduce gastric secretions and increase the risks of developing iron and vitamin B_{12} deficiencies. The nutrition care for gastritis and peptic ulcer disease includes correcting any nutritional deficiencies that develop and eliminating dietary substances that can cause pain or discomfort.

Gastric Surgery

Gastric surgery is sometimes necessary for treating stomach cancers, some ulcer complications, and ulcers that are resistant to drug therapy. In recent years, gastric surgery has also become a popular treatment for severe obesity. Because gastric surgeries can interfere with stomach function either temporarily or permanently, patients generally need to make dietary adjustments afterward.

Stomach cancers are often treated with a **gastrectomy,** a surgical procedure that removes the diseased areas of the stomach. To suppress gastric acid secretion, a **vagotomy** is sometimes performed; this procedure severs the **vagus nerve,** which normally stimulates the cells that produce gastric acid. Because a vagotomy may impair gastric motility, it is sometimes followed by a **pyloroplasty,** which widens the pyloric sphincter to ensure drainage from the stomach to the duodenum. **Bariatric surgery,** the type of surgery that treats severe obesity, was introduced in Chapter 9 (pp. 292–293) and is discussed later in this chapter.

Gastrectomy

Figure 23-3 illustrates some typical gastrectomy procedures. In a partial gastrectomy, only part of the stomach is removed, and the remaining portion is connected to the duodenum or jejunum. In a total gastrectomy, the surgeon removes the entire stomach and connects the esophagus directly to the small intestine.

Nutrition Care after Gastrectomy The primary goals of nutrition care after a gastrectomy are to meet the nutrient needs of the postsurgical patient and promote the healing of stomach tissue. Another goal is to prevent problems that may arise due to altered stomach function. As the next section will describe, some gastric surgeries increase the risk of **dumping syndrome,** a group of symptoms that result when a large amount of food passes rapidly into the small intestine.

Following a gastrectomy, oral intake of fluids and foods is suspended until some healing has occurred, and fluids are supplied intravenously.[22] Ice chips (melted in the mouth), small sips of water, and broth are usually the first fluids given orally. Once fluids are tolerated, patients are offered liquid meals (with no sugars) at first, and they usually progress to solid foods by the fourth or fifth day after surgery. They may receive tube feedings if complications prevent a normal progression to solid foods.[23]

Dietary adjustments after gastrectomy are influenced by the size of the remaining stomach, which influences meal size, and the stomach emptying rate, which affects food tolerances. Initially, the patient is offered small meals and snacks that include only one or two food items; these foods may contain protein (fish, lean meats, and eggs), fat, and complex carbohydrates (bread, potatoes, and vegetables). Depending on the amount of food tolerated, the patient progresses to five or six small meals per day. The patient should avoid sweets and sugars, because they increase osmolarity in the small intestine and potentiate the dumping syndrome (discussed below). Some patients may need to avoid milk products due to lactose intolerance. Soluble fibers may be added to meals to help delay stomach emptying and reduce diarrhea. Although tolerances vary, patients may have difficulty with fatty foods, highly spiced foods, carbonated drinks, caffeine-containing beverages, alcohol, extremely hot or cold foods, peppermint, and chocolate. Liquids are restricted during meals due to the limited stomach capacity and because liquids can

gastrectomy (gah-STREK-ta-mee): the surgical removal of part of the stomach (partial gastrectomy) or the entire stomach (total gastrectomy).

vagotomy (vay-GOT-oh-mee): surgery that severs the vagus nerve in order to suppress gastric acid secretion. This surgery may require a follow-up *pyloroplasty* procedure to allow stomach drainage.

vagus nerve: the cranial nerve that regulates hydrochloric acid secretion and peristalsis. Effects elsewhere in the body include regulation of heart rate and bronchiole constriction.

pyloroplasty (pye-LORE-oh-PLAS-tee): surgery that enlarges the pyloric sphincter.

bariatric (BAH-ree-AH-trik) **surgery:** surgery that treats severe obesity.
• **baros** = weight

dumping syndrome: symptoms that result from the rapid emptying of an osmotic load from the stomach into the small intestine. Early symptoms include nausea, abdominal cramps, weakness, and diarrhea; later symptoms are those of hypoglycemia.

FIGURE 23-3 Typical Gastrectomy Procedures

In a gastrectomy, part or all of the stomach is surgically removed. The dashed lines show the removed section.

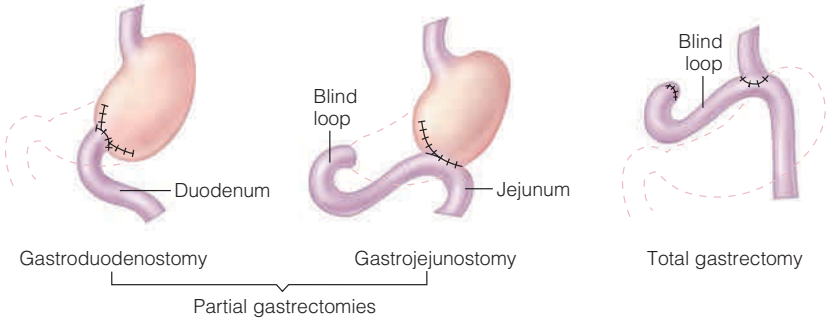


TABLE 23-5 Postgastrectomy Diet

Food Category	Foods Recommended (as tolerated)	Foods to Limit (unless tolerated)
Meat and meat alternates	Lean tender meats, fish, poultry, shellfish, eggs, smooth nut butters	Fried, tough, or chewy meats; frankfurters and sausages; bacon; luncheon meats; dried peas and beans
Milk and milk products	Milk, plain yogurt, mild cheeses	Milk shakes, chocolate milk, fruit yogurt
Breads and cereals	Breads, crackers, bagels, pasta, and breakfast cereals made from enriched white flour (cereals should contain no added sugars)	Breads and cereals with more than 2 grams of fiber per serving; baked goods with dried fruits, nuts, or seeds; granola; frosted cereals; pastries; doughnuts
Vegetables	Tender-cooked vegetables without peels, skins, or seeds; raw lettuce	Raw vegetables (except lettuce), beets, broccoli, brussels sprouts, cabbage, cauliflower, collard and mustard greens, corn, potato skins
Fruit	Canned fruit without added sugars, bananas, melon	Canned fruits in syrup, raw fruits (except bananas and melons), dried fruits, fruit juices
Beverages	Decaffeinated coffee and tea, beverages sweetened with artificial sweeteners	Caffeinated beverages; alcoholic beverages; beverages sweetened with sugars, corn syrup, and honey

SOURCE: American Dietetic Association, *Nutrition Care Manual* (Chicago: American Dietetic Association, 2007).

increase the stomach emptying rate. Table 23-5 lists foods that are often permitted and those that are limited in postgastrectomy diets.[24]

Dumping Syndrome The dumping syndrome is characterized by a group of symptoms resulting from rapid gastric emptying. Ordinarily, the pyloric sphincter controls the rate of flow from the stomach into the duodenum. After some types of stomach surgery, the hypertonic gastric contents are no longer regulated and can rush into the small intestine more quickly after meals, causing a number of unpleasant effects. Early symptoms can occur within 30 minutes and may include nausea, vomiting, abdominal cramping, diarrhea, lightheadedness, rapid heartbeat, and others (see Table 23-6). These symptoms may be due to intestinal distention (which causes the release of an excess amount of vasoactive chemicals), a shift of fluid from blood vessels to the intestine that lowers blood volume, and an increase in peristaltic activity. Several hours later, symptoms of hypoglycemia may occur (see Table 23-6) because the unusually large spike in blood glucose following the meal (due to rapid nutrient influx and absorption) can result in an excessive insulin response.

Dietary adjustments can greatly minimize or prevent dumping syndrome. The goals are to limit the amount of food material that reaches the intestine, slow the

TABLE 23-6 Symptoms of Dumping Syndrome

Early Dumping Syndrome	Late Dumping Syndrome
Symptoms may begin within 30 minutes after eating:	Symptoms may begin 1 to 3 hours after eating:
• Abdominal fullness, cramps	• Anxiety
• Diarrhea	• Confusion, difficulty thinking
• Dizziness	• Headache
• Flushing, sweating	• Hunger
• Nausea and vomiting	• Palpitations
• Rapid heartbeat	• Sweating
• Weakness, feeling faint	• Weakness, feeling faint

rate of gastric emptying, and reduce foods that increase hypertonicity. Therefore, meal size is limited, fluids are restricted during meals, and sugars (including milk sugar) are restricted. The "How to" below lists practical suggestions for reducing the occurrence of dumping syndrome. In some cases, drugs that inhibit gastrointestinal motility (such as octreotide) ◆ may help. The Case Study on p. 745 provides the opportunity to design a menu for a postgastrectomy patient who is at risk for dumping syndrome.

◆ *Octreotide* inhibits gastrointestinal motility, thereby slowing both gastric emptying and transit time in the small intestine.

Postsurgical Complications and Nutrition Status Substantial weight loss can sometimes be an unintended consequence of gastrectomy. It may take time for a postgastrectomy patient to learn the amount of food that can be consumed without causing discomfort. The symptoms associated with meals may lead to food avoidance, weight loss, and eventually, malnutrition. Other nutrition problems that may occur after gastrectomy include the following:[25]

- *Fat malabsorption.* Fat digestion and absorption may be impaired due to the accelerated transit of food material, which prevents the normal mixing of fat with lipase and bile. If the duodenum has been removed or bypassed, less lipase is secreted into the intestine for fat digestion. Another potential problem is bacterial overgrowth in the small intestine, which interferes with bile function. ◆ Fat malabsorption can lead to deficiencies of fat-soluble vitamins and some minerals. Supplemental pancreatic enzymes are sometimes provided to improve fat digestion. Medium-chain triglycerides, which are more easily digested and absorbed, can be used to supply additional fat kcalories.

◆ Bacterial overgrowth is described in Chapter 24.

- *Bone disease.* Osteoporosis and osteomalacia are common outcomes following a gastrectomy, and they are most likely a consequence of vitamin D and calcium deficiencies.[26] The fat malabsorption discussed earlier can also cause malabsorption of vitamin D and calcium; ◆ furthermore, patients at risk of dumping syndrome may need to avoid milk products, which are among the best sources of these nutrients. Bone density should be monitored during the years following surgery, and supplementation of calcium and vitamin D is often recommended.

◆ Fat malabsorption reduces calcium absorption because the negatively charged fatty acids combine with calcium (which is positively charged) and prevent its absorption.

- *Anemia.* After gastrectomy, iron and vitamin B_{12} deficiencies are common. The reduced gastric secretions impair the absorption of both iron and vitamin B_{12}. If the duodenum has been removed or is bypassed, the risk of iron deficiency increases because the duodenum is a major site of iron absorption. Supplementation of both iron and vitamin B_{12} is usually warranted after surgery.

HOW TO Alter the Diet to Reduce Symptoms of Dumping Syndrome

Dietary adjustments can minimize or prevent symptoms of dumping syndrome. The following suggestions often help:

- Eat smaller meals to fit the reduced capacity of the stomach. Increase the number of meals consumed daily so that energy intake is adequate.
- Eat in a relaxed setting. Eat slowly and chew food thoroughly.
- Limit the amount of fluid taken with meals. Avoid consuming beverages within 45 minutes before and after meals, but be sure to include adequate fluid intake during the day to avoid dehydration.
- Avoid juices and sweetened beverages and foods that contain large amounts of sugar. Avoid carbonated beverages if they cause bloating.
- Use artificial sweeteners to sweeten beverages and desserts.
- Avoid foods and beverages that are very hot or very cold, unless tolerated.
- Include fiber-rich foods in each meal. Sometimes adding soluble fibers like pectin or guar gum to meals can help to control symptoms.
- Avoid milk and most milk products, which are high in lactose. Enzyme-treated milk should also be avoided because the breakdown products of lactose (glucose and galactose) can also cause symptoms. Cheese may be better tolerated, because its lactose content is low. Make an effort to consume nonmilk calcium sources such as green leafy vegetables, tofu, and fish with bones.
- If symptoms of hypoglycemia continue, try including a protein-rich food in each meal.
- Lie down for 20 to 30 minutes (or longer) after eating to help slow the transit of food to the small intestine. While eating a meal, sit upright.

CASE STUDY Biology Teacher Requiring Gastric Surgery

Marie Erwin, a 58-year-old biology teacher, was admitted to the hospital for gastric surgery after numerous medical treatments failed to manage her severe peptic ulcer disease. A gastrojejunostomy was performed, and after about 24 hours, Mrs. Erwin was able to take small sips of warm water. The health care team anticipates multiple nutrition-related problems and is taking measures to prevent them.

1. Review Figure 23-3 to better understand Mrs. Erwin's surgical procedure. Consider the possibilities that she might experience the following symptoms: early satiety, nausea and vomiting, weight loss, dumping syndrome, fat malabsorption, anemia, and bone disease. Explain why each of these conditions may occur.
2. What type of diet will the physician prescribe for Mrs. Erwin after she begins eating solid foods? Create a day's worth of menus, using foods from Table 23-5.
3. What advice can you give Mrs. Erwin that will help to prevent dumping syndrome? List several foods from each major food group that may cause symptoms of dumping syndrome.

Bariatric Surgery

The most popular surgical options for weight reduction, the gastric bypass and gastric banding procedures, were introduced in Chapter 9 (see Figure 9-5 on p. 293). The gastric bypass operation, ◆ which accounts for more than 70 percent of bariatric surgeries,[27] constructs a small gastric pouch that reduces stomach capacity and thereby restricts meal size. In addition, the surgeon alters the digestive route by connecting the pouch directly to the jejunum; this reduces nutrient absorption because the nutrients bypass a significant portion of the small intestine. In the gastric banding procedure, a gastric pouch is created using a fluid-filled inflatable band. Adjusting the band's fluid level can tighten or loosen the band and alter the size of the opening between the pouch and the rest of the stomach. A smaller opening reduces the speed at which the pouch is emptied and prolongs the sense of fullness after a meal. Whereas the gastric bypass operation is somewhat permanent, the gastric banding procedure is fully reversible.

◆ The gastric bypass surgery is also known as a *Roux-en-Y gastric bypass* because the reconstructed small intestine resembles the letter *Y*.

The weight loss achieved after gastric bypass and gastric banding is similar, although patients often lose weight faster after the gastric bypass procedure. Although research results vary, the average long-term (5- to 7-year) weight loss following bariatric surgery is approximately 55 percent of excess weight.[28]

Although bariatric surgeries are effective treatments for morbid obesity, patients should have realistic expectations about the amount of weight they are likely to lose, the diet they will need to follow, and the complications that may ensue. Some types of bariatric surgery can dramatically affect health and nutrition status, and patients may require lifelong management.

Dietary Guidelines after Bariatric Surgery The gastric pouch created by surgery eventually expands to hold about $^1/_2$ cup of food, but its initial capacity is only a few tablespoons. Only sugar-free clear liquids and low-fat broths are given on the day following bariatric surgery.[29] Afterward, patients consume a liquid diet at first, followed by pureed foods and then solid foods; soft foods like tender meats, tender-cooked vegetables, and canned fruits are tolerated most easily. Only small portions should be consumed, because overeating can stretch the gastric pouch. Similarly, fluids must be consumed separately from meals to avoid excessive distention.

Other nutrition-related concerns include the following:

- *Protein intake.* The protein recommendation for bariatric patients is 1.5 grams of protein per kilogram of body weight; however, intakes are often lower than recommended.[30] Patients are generally instructed to eat high-protein foods before consuming other foods in a meal and to consume liquid protein supplements regularly.

HOW TO Alter Dietary Habits to Achieve and Maintain Weight Loss after Bariatric Surgery

Patients need to learn new dietary habits after bariatric surgery. The following recommendations may help:

- Chew food thoroughly, and consume only small amounts. Use a small spoon, and take small bites. Relax and enjoy the meal, taking at least 20 minutes to eat.
- Understand that at first, the appropriate portion of each food served at mealtime may be only a few spoonfuls. Learn to recognize the sensations that occur when the gastric pouch is full. Signs of fullness may include pressure in the stomach region, a slight feeling of nausea, or pain in the upper chest or shoulder.
- Learn to recognize foods that cause problems. Foods that are dry, sticky, or fibrous may be difficult to tolerate during the weeks after surgery.
- To control vomiting, try eating smaller volumes of food, eating more slowly, and avoiding foods that are known to cause difficulty. Continued vomiting may be a sign that appropriate food behaviors are not being maintained.
- Eat only at mealtimes. Snacking throughout the day can become a bad habit that causes weight to be regained.
- Avoid consuming liquids within 45 minutes of mealtime. Consume liquids between meals only. Avoid high-kcalorie drinks such as soda, alcoholic beverages, and milk shakes. Carbonated beverages increase stomach gas and may cause bloating.
- Drink adequate fluids between meals to avoid dehydration. Most people meet a substantial portion of their fluid needs by eating foods, but a patient who has had bariatric surgery cannot do this. Therefore, fluid intakes need to be increased after surgery.
- Engage in regular physical activity. Activity is a valuable aid to weight maintenance and can help to maintain lean tissue while weight is being lost.

- *Vitamin and mineral deficiencies.* Bariatric patients have a high risk of developing nutrient deficiencies due to reduced food intake, reduced gastric secretions, and nutrient malabsorption. Supplemental vitamin B_{12}, iron, and calcium are usually recommended after surgery. In addition, a daily multivitamin/mineral supplement can ensure that patients meet their needs for other nutrients.
- *Foods to avoid.* Patients may find some foods difficult to manage; dry, doughy, or fibrous foods may cause pain or vomiting. Foods that are often problematic after bariatric surgery include sticky foods like rice, pasta, and soft breads; tough or chewy meats; and foods that have seeds, peels, or husks.
- *Dumping syndrome.* To avoid symptoms of dumping syndrome, gastric bypass patients must carefully control food portions, avoid foods high in sugars, and consume liquids between meals (review the "How to" on p. 744).

After bariatric surgery, patient education and counseling are critical for weight loss and weight management; patients also need to learn the elements of a healthy diet. The "How to" on this page includes additional dietary suggestions for patients who have undergone bariatric surgery.

Postsurgical Concerns in Gastric Bypass Surgery The complications that arise after gastric bypass surgery are similar to those that arise after gastrectomy and may include fat malabsorption, bone disease, and anemia. Rapid weight loss also increases a person's risk of developing gallbladder disease; patients at especially high risk sometimes have their gallbladders removed while undergoing bariatric surgery. After weight loss, plastic surgery may be necessary to remove extra skin, especially on the abdomen, buttocks, hips, and thighs.

IN SUMMARY

Gastric surgeries are used to treat cancer, peptic ulcer complications, and obesity. This surgery may alter stomach size or function, so dietary adjustments are required afterward. Common postsurgical complications include fat malabsorption, bone disease, anemia, and dumping syndrome. After bariatric surgery, patients must learn to consume appropriate food portions; use dietary supplements to prevent nutrient deficiencies; and choose foods that are unlikely to cause abdominal discomfort, vomiting, or dumping syndrome.

Clinical Portfolio

CENGAGENOW™
academic.cengage.com/login

1. The diets described in this chapter are highly individualized: a particular food may cause discomfort for one person and have no effect on another. Describe some practical ways to keep track of food intolerances.

2. Although some individuals may require a mechanically altered diet for just a few weeks, others may have medical problems that require long-term use of such diets. Consider the difference between working with a person who has had a swallowing problem for years and a person who recently had mouth surgery and is just beginning to eat again.
   - Explain how the needs of these individuals may differ. What nutrition-related problems may develop if a person has been following a restrictive dysphagia diet for several years?
   - Using Table 23-2 and the "How to" on p. 735, create a day's worth of menus for a person who requires long-term use of a pureed dysphagia diet and tolerates only liquids that have a honeylike consistency.

- Learn more about *Helicobacter pylori* from the Helicobacter Foundation: **www.helico.com**

NUTRITION ASSESSMENT CHECKLIST for People with Upper GI Tract Disorders

Medical History

Check the medical history to uncover conditions or treatments that may:

- Lead to dry mouth
- Interfere with chewing or swallowing
- Lead to dyspepsia, nausea, or vomiting

Check for a medical diagnosis of:

- Gastritis or peptic ulcer
- GERD
- Hiatal hernia
- Pernicious anemia

For a patient who has undergone gastric surgery, check for the following complications:

- Anemia
- Bone disease
- Dumping syndrome
- Fat malabsorption

Medications

Record all medications and note:

- Aspirin or NSAID use in patients with gastritis or peptic ulcer disease
- Medications that may cause dry mouth
- Medications that may cause nausea and vomiting

To help alleviate nausea, suggest that medications be taken with food, when possible.

Dietary Intake

To devise an acceptable meal plan, obtain:

- An accurate and thorough record of food intake
- A record of foods that provoke symptoms of dyspepsia, nausea, GERD, gastritis, peptic ulcers, or dumping syndrome

For patients on long-term dysphagia diets, monitor:

- Appetite
- Tolerances to foods
- Variety of foods offered and regularly consumed

Anthropometric Data

Measure baseline height and weight. Address weight loss early to prevent malnutrition for patients with:

- Dysphagia or difficulty chewing
- Dyspepsia or nausea of long duration
- Malabsorption
- Dumping syndrome

Laboratory Tests

Check laboratory tests for signs of dehydration for patients with:

- Dumping syndrome
- Persistent vomiting

Check laboratory tests for nutrition-related anemia in patients with:

- Conditions that require long-term use of antisecretory medications
- Gastritis
- Previous gastric surgeries

Physical Signs

Look for physical signs of:

- Dehydration—in patients with persistent vomiting or dumping syndrome
- Iron and vitamin B_{12} deficiencies—in patients with hypochlorhydria or achlorhydria

STUDY QUESTIONS

CENGAGENOW™

To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Provide examples of conditions that can interfere with swallowing. Describe how diets are adjusted to meet the needs of people with dysphagia. (pp. 731–734)
2. Discuss ways to provide appetizing meals for people consuming mechanically altered foods. (p. 735)
3. Identify the symptoms, causes, and complications of gastroesophageal reflux disease (GERD). What lifestyle modifications can benefit patients with GERD? (pp. 734–737)
4. What are possible causes of nausea and vomiting? Discuss interventions that may help. (p. 739)
5. Specify the common causes of gastritis and peptic ulcer disease. Explain the possible consequences of these diseases. Describe the role of diet therapy for both conditions. (pp. 739–741)
6. Describe the gastric disorders that may benefit from gastric surgery. What dietary adjustments are usually required after a gastrectomy procedure? (pp. 741–744)
7. What complications may arise after gastric surgery? Discuss the dietary interventions that may help to prevent these consequences. (pp. 743–744)
8. Describe the surgical procedures used to treat morbid obesity. Discuss the dietary recommendations for patients who have undergone bariatric surgery. (pp. 745–746)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 749.

1. If a patient with dysphagia has difficulty swallowing solids but can easily swallow liquids:
   a. the problem is probably a motility disorder.
   b. the patient most likely has achalasia.
   c. the problem is probably an esophageal obstruction.
   d. the patient may also develop oropharyngeal dysphagia.
2. The health practitioner working with a patient with dysphagia should recognize that:
   a. only pureed foods should be given to minimize the risk of aspiration.
   b. the patient can have any food that can be comfortably and safely chewed and swallowed.
   c. highly seasoned foods are often restricted.
   d. conventional diets are unable to meet total nutrient needs, and supplements are always necessary.

3. Gastroesophageal reflux disease (GERD) is:
   a. characterized by frequent backflow of the stomach's gastric secretions into the esophagus.
   b. a protuberance of a portion of the stomach above the lower esophageal sphincter.
   c. an erosion of the lining of the stomach caused by excess acid in gastric secretions.
   d. an obstruction of the lower esophagus that results in dysphagia.
4. Conditions associated with an increased risk of developing GERD include:
   a. hiatal hernia.
   b. asthma.
   c. pregnancy.
   d. all of the above.
5. For the patient with persistent vomiting, the major nutrition-related concern(s) is/are:
   a. dehydration and malnutrition.
   b. reflux esophagitis.
   c. dyspepsia.
   d. peptic ulcers.
6. Chronic gastritis frequently leads to:
   a. dumping syndrome.
   b. bone disease.
   c. iron and vitamin B_{12} deficiencies.
   d. excessive hydrochloric acid secretion.
7. The primary cause of most peptic ulcers is:
   a. consumption of spicy foods.
   b. hypochlorhydria.
   c. smoking cigarettes.
   d. *Helicobacter pylori* infection.
8. Foods discouraged for patients with gastritis or active ulcers include those that:
   a. are high in fiber.
   b. irritate the gastric mucosa.
   c. are easy to swallow.
   d. contain simple sugars.
9. People at risk of dumping syndrome should generally avoid:
   a. high-fiber foods.
   b. sweets and sugars.
   c. beverages.
   d. bread and potatoes.
10. The health practitioner assessing a patient who underwent a gastrectomy several years ago should be alert to signs of:
   a. dysphagia.
   b. GERD.
   c. anemia.
   d. gastritis.

Dental Health and Chronic Illness

© Ken Sherman/PhotoTake

The relationships between nutrition and dental health were discussed earlier in this book. Chapter 4 described the effects of sugar and other fermentable carbohydrates on tooth decay. Chapter 13 explained how fluoride can help to prevent dental caries. Chapter 15 discussed the development of tooth decay in babies who are given bottles for prolonged periods. This highlight identifies other types of dental problems. It includes examples of how chronic illnesses may influence the development of dental diseases and, conversely, how dental diseases may increase the risks of developing chronic illnesses. Related terms are defined in the accompanying glossary.

Periodontal Disease

Recall from Chapter 4 that dental caries develops when the bacteria that reside in dental plaque ferment sugars and produce acid that dissolves tooth enamel (review Figure 4-14 on p. 119). Deposits of plaque can thicken and lead to other dental problems as well. As plaque accumulates on the tooth surface, it fills with calcium and phosphate, eventually forming **dental calculus.** Calculus may develop either at the gum surface or in the crevice between the gum and a tooth; its presence may cause further plaque retention. The buildup of plaque and calculus increases the likelihood of infection and subsequent inflammation.

Periodontal disease refers to inflammatory conditions involving the **periodontium**—the tissues that support the tooth in its bony socket. The periodontium includes the gums (called **gingiva**), other connective tissues surrounding the tooth, and the bone underneath. Inflammation of the gums, called **gingivitis,** is characterized by redness, bleeding, and swelling of gum tissue. **Periodontitis** is an inflammation of the other tissues surrounding the tooth. As plaque invades the space below the gum line, the combination of toxic bacterial by-products and the body's immune response can destroy the tissues holding a tooth in place. Left untreated, the tissues and bone of the peridontium may ultimately be destroyed, leading to permanent tooth loss.

Risk Factors

Dental plaque is the major risk factor associated with periodontal disease, and the severity of the disease is related to the amount of plaque present. Tobacco smoking is another factor, possibly because of its destructive effects on cellular immune responses.[1] The risk of developing periodontal disease is especially high if a person has a chronic illness that impairs immune status, such as diabetes mellitus or HIV infection. Other risk factors include genetic susceptibility, stress, and dental conditions that increase plaque accumulation, such as poorly aligned teeth or calculus buildup. Strategies for reducing risk focus on improving oral hygiene (proper brushing and flossing) and encouraging smoking cessation.

Signs and Symptoms

Periodontal disease typically begins with gingivitis; the gums may bleed readily from brushing or flossing and be tender and swollen. The gap between an infected gum and a tooth usually deepens, allowing food particles to get caught easily. A bad taste in the mouth or persistent bad breath is sometimes the first sign

GLOSSARY

dental calculus: mineralized dental plaque, often associated with inflammation and bleeding.

gingiva (jin-JYE-va, JIN-jeh-va): the gums.

gingivitis (jin-jeh-VYE-tus): inflammation of the gums; characterized by redness, swelling, and bleeding.

periodontal disease: a disease that affects the connective tissue structures that support the teeth.

periodontitis: inflammation or degeneration of the tissues that support the teeth.

periodontium: the tissues that support the teeth, including the gums, cementum (bonelike material covering the dentin layer of the tooth), periodontal ligament, and underlying bone.
- **peri** = around, surrounding
- **odont** = tooth

Sjögren's syndrome: an autoimmune disease characterized by the destruction of secretory glands, especially those that produce saliva and tears, resulting in dry mouth and dry eyes.

xerostomia: dry mouth caused by reduced salivary flow.
- **xero** = dry
- **stomia** = mouth

Reminder: Dental caries refers to tooth decay. *Dental plaque* is an accumulation of bacteria and their by-products that grow on teeth and can lead to dental caries and gum disease.

© CNRI/Photo Researchers, Inc.

Periodontal disease destroys the tissues and bones that hold teeth in place.

of gingivitis. In severe cases, pus may surround the teeth and gums. The teeth may be sensitive and chewing painful. If bone is destroyed, the affected gums usually recede, and teeth may loosen or change position.

Treatment

Treatment of periodontal disease depends on the extent of damage. In mild cases, deep cleaning and proper oral hygiene may reverse the condition. Antimicrobial mouth rinses and topical antibiotics are often prescribed to control infection. Surgical approaches are sometimes necessary to remove plaque or calculus deposits underneath gum tissue or to replace tissues that have been destroyed.

Dry Mouth

Secretions of the salivary glands protect the teeth and the mouth's soft tissues. Saliva lubricates oral tissues and contains antimicrobial proteins to defend against bacteria and fungi. The buffers in saliva raise the mouth's pH so that tooth enamel is protected from the acid produced by caries-causing bacteria. The calcium and phosphate concentrations of saliva help to prevent dissolution of enamel. Thus saliva helps to control plaque formation, prevent infection within the mouth, and maintain tooth enamel. If salivary secretions are low or absent, the risk of developing dental caries and periodontal disease increases.[2]

Dry mouth **(xerostomia),** caused by reduced salivary flow, is a side effect of many medications and is associated with a number of diseases and disease treatments. Antihistamines, antihypertensive agents, antidepressants, decongestants, and other medications can cause dry mouth. Poorly controlled diabetes mellitus is often associated with dry mouth, as are conditions that directly affect salivary gland function, such as **Sjögren's syndrome.** Radiation therapy used to treat head and neck cancers often damages salivary glands, sometimes permanently. Mouth breathing is also a common cause of dry mouth.[3]

TABLE H23-1 Suggestions for Managing Dry Mouth

- Take frequent sips of water or a sugarless beverage.
- Use sugarless candy or gum to help stimulate salivary flow.
- Suck on ice cubes or frozen fruit juice bars (unless their coldness causes discomfort).
- Avoid citrus juices and spicy or salty foods if they cause mouth irritation.
- Avoid dry foods like toast, chips, and crackers.
- Avoid caffeine, alcohol, and smoking, which may dry the mouth.
- Consume foods that have a high fluid content, such as soups, stews, sauces and gravies, yogurt, and pureed fruits.
- Try over-the-counter saliva substitutes (available as gels, sprays, and tablets), especially just before meals and at bedtime.
- Try rinsing the mouth with small amounts of vegetable oil or softened margarine.
- Use a humidifier during the night.
- Pay strict attention to oral hygiene, brushing and flossing at least twice daily. Try to brush immediately after each meal.
- Avoid alcohol- and detergent-containing mouthwashes, which may dry and irritate the mouth.
- If dry mouth is caused by a medication, ask your physician about possible alternatives.
- Ask your physician if using a medication to stimulate saliva secretion may be of benefit; examples include nicotinic acid tablets and pilocarpine.

A reduction in salivary flow can impair health in other ways as well. Dry mouth may interfere with speech and cause bad breath. Mouth infections are more common. Chewing and swallowing are more difficult, and taste sensation is diminished. Dentures may be uncomfortable to wear, and ulcerations may develop where they contact the mouth. Dry mouth may cause a person to reduce food intake and thereby increase malnutrition risk. Table H23-1 lists suggestions that may help to manage dry mouth.

Dental Health and Chronic Illness

Maintaining dental health is sometimes challenging for a person with a chronic illness. As mentioned earlier, many medications can reduce salivary secretions, along with the immune protection that saliva provides. This section describes how several conditions may upset oral health and increase the risks of developing dental problems.

Diabetes Mellitus

For a number of reasons, periodontal disease is more prevalent among people with diabetes mellitus, especially those whose diabetes is poorly controlled. People with diabetes often have impaired immune responses and a greater susceptibility to infections. Diabetes also favors the growth of bacteria that tend to infect periodontal tissues. The damaging effects of hyperglycemia weaken the collagen structure of tissues, making them more vulnerable. In addition, people with diabetes tend to have

higher plaque accumulations and dry mouth, predisposing them to periodontal disease.[4]

Because the risk of developing dental caries and oral fungal infections is greater for people with diabetes, they must pay strict attention to oral hygiene. Smoking is discouraged because it can increase periodontal disease risk nearly 10-fold in people with diabetes.[5] Health care providers should advise patients with diabetes that glucose control and routine dental care are critical to preventing periodontal disease.

Human Immunodeficiency Virus (HIV) Infection/AIDS

HIV infection is characterized by compromised immunity, and the risk of developing periodontal disease is closely linked to the extent of HIV infection. In untreated persons, fungal and viral infections are common and may cause burning in the mouth and painful ulcerations. The current use of antiretroviral therapies, however, has substantially reduced the incidence of oral infections in HIV-positive persons.[6] Those at greatest risk of developing dental disease include smokers, individuals who decline therapy, and patients in advanced stages of disease.[7] HIV-infected individuals often have dry mouth as a result of medications or salivary gland dysfunction.[8]

Oral Cancers

Radiation treatment of oral cancers can cause serious oral and dental complications.[9] The inflammation and tissue damage may be so severe that the radiation treatment may need to be halted or the intensity reduced substantially. Radiation can also reduce salivary flow, causing the problem of dry mouth described earlier. Other complications include fungal and viral infections, changes in taste sensation, and tissue and muscle scarring (which often reduces chewing ability). To minimize complications, dental care is often initiated before radiation therapy begins.

Dental Health and Disease Risk

Dental diseases may have adverse effects on health beyond their effects on teeth.[10] The bacteria that reside on dental tissues can enter the bloodstream and cause infections elsewhere in the body. Evidence supports a link between dental bacteria and other conditions, including the following:

- *Systemic inflammation.* The inflammatory process induced by periodontal disease increases levels of cytokines and other mediators that have systemic effects. Systemic inflammation may contribute to the development of certain chronic illnesses, including heart disease and diabetes.
- *Respiratory illnesses.* The teeth of hospital patients often become colonized with bacteria that cause respiratory illnesses. In one study, only patients whose teeth were colonized by respiratory pathogens ended up with pneumonia.[11]
- *Atherosclerosis and heart disease.* Bacteria associated with gingivitis can attack the cells lining the blood vessels, possibly affecting the process of atherosclerosis. In one study, researchers found a significant association between serum antibodies to periodontal bacteria and the incidence of heart disease.[12]
- *Diabetes mellitus.* The presence of periodontal disease can make it more difficult for persons with diabetes to attain glucose control.

Although this evidence is suggestive, researchers studying the effects of periodontal disease on health have yet to prove cause-and-effect relationships between dental health and other conditions. Additional studies will help to clarify the complex interactions between dental disease and chronic illnesses.

Nutrition in the Clinical Setting

Disorders affecting the lower gastrointestinal tract can interfere substantially with a patient's diet and lifestyle. Patients with some diseases must adhere to diets that are complicated and difficult to follow. Furthermore, foods that patients tolerate can vary considerably. In follow-up visits, health care professionals should ensure that patients understand the diet prescription and help to pinpoint difficult foods. They can also suggest ways to make restrictive diets more acceptable.

CHAPTER 24

Lower Gastrointestinal Disorders

CHAPTER OUTLINE

Common Intestinal Problems • Constipation • Intestinal Gas • Diarrhea

Malabsorption Syndromes • Fat Malabsorption • Bacterial Overgrowth

Conditions Affecting the Pancreas • Pancreatitis • Cystic Fibrosis

Conditions Affecting the Small Intestine • Celiac Disease • Inflammatory Bowel Diseases • Short Bowel Syndrome

Conditions Affecting the Large Intestine • Irritable Bowel Syndrome • Diverticular Disease of the Colon • Colostomies and Ileostomies

HIGHLIGHT 24 Probiotics and Intestinal Health

This chapter discusses medical conditions that can upset the digestive and absorptive functions of the lower gastrointestinal (GI) tract. As you may recall from Chapter 3, the lower GI tract consists of the small intestine (the duodenum, jejunum, and ileum), the large intestine, the rectum, and the anus. The digestion and absorption of nutrients occur primarily in the small intestine. The pancreas and gallbladder support these complex functions by delivering digestive secretions to the duodenum, the segment of small intestine closest to the stomach. The large intestine reabsorbs water and facilitates the excretion of waste material. Figure 24-1 on p. 756 illustrates the lower GI tract and related organs and reviews the functions of each organ, and pp. 72–74 in Chapter 3 provide additional detail.

Common Intestinal Problems

Nearly all people experience occasional intestinal problems, which usually clear up without medical treatment. Intestinal discomfort can sometimes drive a person to seek medical attention, however, and the symptoms may be evidence of a serious intestinal disorder or other illness. The most common intestinal problems and their causes and treatments are discussed below.

Constipation

A medical diagnosis of constipation is based, in part, on a defecation frequency of fewer than three bowel movements per week. Other symptoms may include the passage of hard stool and excessive straining during defecation. In some cases, however, a person's perception of constipation may be due to a mistaken notion of what constitutes "normal" bowel habits, so the person's expectations about bowel function may need to be addressed.

Constipation is much more prevalent among women than men and is a common complaint during pregnancy. The incidence of constipation increases with

FIGURE 24-1 The Lower GI Tract and Related Organs

Stomach
Adds acid, enzymes, and fluid. Churns, mixes, and grinds food to a liquid mass.

Pyloric sphincter
Allows passage from stomach to small intestine. Prevents backflow from small intestine.

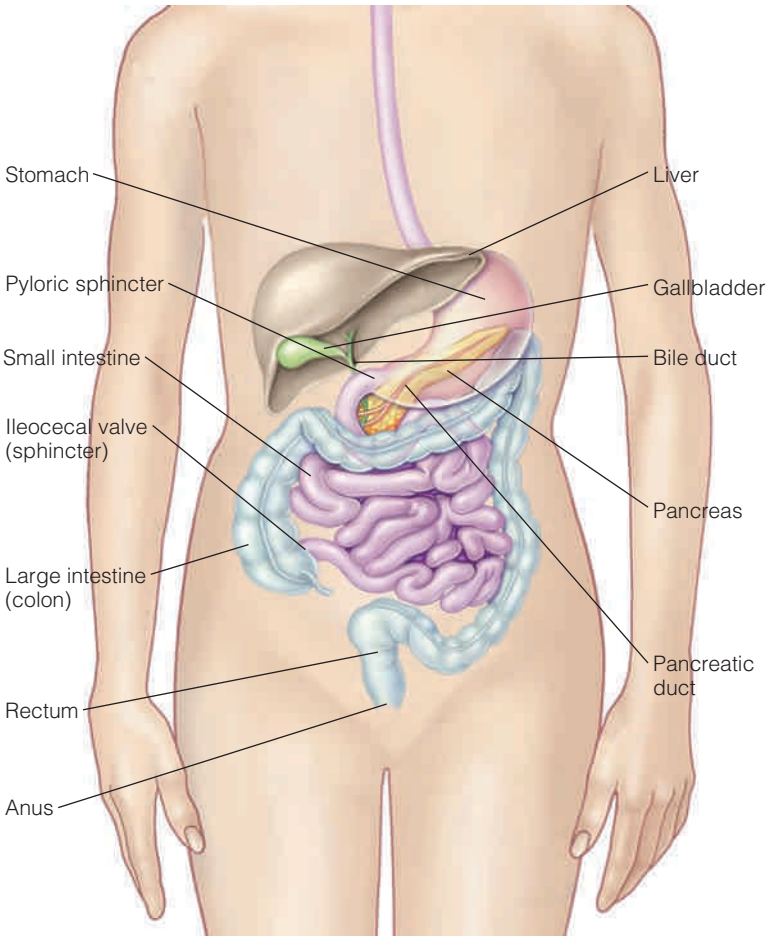
Small intestine
Produces enzymes that digest energy-yielding nutrients to smaller nutrient particles. Cells absorb nutrients into blood and lymph.

Ileocecal valve (sphincter)
Allows passage from small to large intestine. Prevents backflow from large intestine and controls transit through intestine.

Large intestine (colon)
Reabsorbs water and minerals. Passes waste (fiber and some water) to rectum.

Rectum
Stores waste prior to elimination.

Anus
Holds rectum closed. Opens to allow elimination.



Liver
Manufactures bile salts (detergent-like substances), to help digest fats.

Gallbladder
Stores bile until needed.

Bile duct
Conducts bile from liver into small intestine.

Pancreas
Manufactures enzymes to digest energy-yielding nutrients and bicarbonate to neutralize acidic stomach contents that enter the small intestine. (Also produces insulin and glucagon.)

Pancreatic duct
Conducts pancreatic juice from pancreas into small intestine.

aging, although elderly individuals tend to find straining during defecation to be a greater problem than infrequent defecation.[1]

Causes of Constipation In Western societies, constipation generally correlates with low-fiber diets, low food intake, and physical inactivity. All of these factors can extend transit time, leading to increased water reabsorption within the colon and dry, hard stools that are difficult to pass. In addition, the frequency and duration of peristaltic contractions are reduced in some patients with constipation.[2]

Medical conditions often associated with constipation include diabetes mellitus, hypothyroidism, and chronic kidney disease. Neurological conditions such as multiple sclerosis, Parkinson's disease, and spinal cord injuries may cause motor problems that lead to constipation. During pregnancy, women may experience constipation when the enlarged uterus presses against the rectum and colon. Constipation is also a common side effect of several classes of medications and some dietary supplements, including opiate-containing analgesics, tricyclic antidepressants, anticonvulsants, calcium channel blockers, aluminum-containing antacids, and iron and calcium supplements.

Treatment of Constipation The primary treatment for constipation is a gradual increase in fiber intake to about 20 to 25 grams per day.[3] ◆ High-fiber diets increase

◆ The fiber DRI for women and men aged 19 to 50 years are 25 and 38 grams, respectively. Recommendations for increasing fiber intake are described on pp. 124–125, and Appendix H includes the fiber values of most common foods.

stool weights and promote a more rapid transit of materials through the colon. Foods that increase stool weight the most are wheat bran, fruits, and vegetables.[4] Bran intake can be increased by adding bran cereals and whole wheat bread to the diet or by mixing bran powder with beverages or foods. The transition to a high-fiber diet may be difficult for some people because it can increase intestinal gas, so high-fiber foods should be added gradually, as tolerated. Fiber supplements such as methylcellulose (Citrucel), psyllium (Metamucil, Fiberall), and polycarbophil (a synthetic fiber) are also effective (see Table 24-1); these supplements can be mixed with beverages and taken several times daily. Unlike other fibers, methylcellulose and polycarbophil do not increase intestinal gas.

Several other measures may also help constipation. Consuming adequate fluid prevents dehydration, which draws water from the colon to increase hydration in the rest of the body. Adding prunes or prune juice to the diet is often recommended because prunes contain compounds that have a mild laxative effect. Increasing daily exercise can help to stimulate peristalsis.

© Andrew McClenaghan/Photo Researchers, Inc.

High-fiber foods promote regular bowel movements.

Laxatives Many laxatives can be purchased without prescription. They work by increasing stool weight, increasing the water content of the stool, or stimulating peristaltic contractions. Table 24-1 includes examples of common laxatives and describes their modes of action. Enemas and suppositories (chemicals introduced into the rectum) are also used to promote defecation; they work by distending and stimulating the rectum or by lubricating the stool.

Medical Interventions Patients with severe constipation who do not respond to dietary or laxative treatments may require medications that stimulate colonic contractions. Physical therapy and biofeedback techniques are sometimes successful in training patients to relax their pelvic muscles more effectively. Surgical interventions are a last resort and include colonic resections and colostomy operations, which are discussed later in this chapter.

TABLE 24-1 Laxatives and Bulk-Forming Agents

Laxative Type	Active Ingredients	Product Examples	Method of Action	Cautions
Fiber (bulk formers)	Methylcellulose, polycarbophil, psyllium, malt soup extract	Metamucil, Citrucel, FiberLax	Fiber supplements increase stool weight and aid in formation of soft, bulky stools. Similar effects are achieved by adding bran to the diet. For mild constipation. Safe for long-term use.	Some fiber supplements may increase flatulence. Psyllium may cause an allergic reaction.
Emollients (stool softeners)	Docusate sodium	Colace	Detergent action promotes the mixing of water with stools. Prevents formation of dry, hard stools.	Do not increase stool weight. Limited effectiveness.
Nonabsorbable sugars (osmotic laxatives)	Lactulose, sorbitol, mannitol	Cephulac	Unabsorbed sugars attract water to large intestine and promote softer stools. Must be used for several days to take effect. Safe for long-term use.	May cause flatulence and cramps. Can lose effectiveness over time.
Saline laxatives (osmotic laxatives)	Magnesium hydroxide, magnesium citrate, sodium sulfate	Milk of magnesia	Unabsorbed salts attract and retain water in large intestine and stimulate contractions.	May cause bloating and watery stools or diarrhea. Should be used with caution. Avoid using in renal patients and children.
Stimulant or irritant laxatives	Senna, bisacodyl, cascara, castor oil, aloe	Ex-Lax, Correctol, Dulcolax	Act as local irritants to colonic tissue; stimulate peristalsis and mucosal secretions. For moderate to severe constipation. Long-term use is discouraged.	Usually given only after milder treatments fail. May alter fluid and electrolyte balances. May lead to laxative dependency.

TABLE 24-2 Foods That May Increase Intestinal Gas

- Apples
- Beer
- Broccoli
- Brussels sprouts
- Cabbage
- Carbonated beverages
- Cauliflower
- Corn
- Dried beans and peas
- Fruit juices
- Leeks
- Milk products (if patients are lactose intolerant)
- Onions
- Peanuts
- Pears
- Potatoes
- Turnips

◆ Reminder: The *soluble fibers* in foods are more readily fermented in the small intestine than the *insoluble fibers.*

Intestinal Gas

As mentioned in the previous section, increased intestinal gas **(flatulence)** can be an unpleasant side effect of consuming a high-fiber diet. The undigested fibers pass into the colon, where they are fermented by bacteria, which produce gas as a by-product. ◆ Other incompletely digested or poorly absorbed carbohydrates have similar effects; these include fructose, sugar alcohols (sorbitol, mannitol, and maltitol), the indigestible carbohydrates in beans (raffinose and stachyose), and some forms of resistant starch, found in grain products and potatoes. Table 24-2 lists examples of foods commonly associated with excessive gas production, although individual responses vary. Malabsorptive disorders (discussed later in this chapter) can cause considerable flatulence because the undigested nutrients pass to the colon, where they are metabolized by colonic bacteria. Swallowed air that is not expelled by belching may travel to the intestines and be a source of intestinal gas (see p. 95).

Many people blame abdominal bloating and pain on excessive gas, but these symptoms do not correlate well with increased intestinal gas.[5] In fact, most people who self-diagnose a flatulence problem have no more intestinal gas than others. Individuals who frequently experience symptoms of abdominal bloating and pain are sometimes diagnosed with irritable bowel syndrome (see pp. 774–776) or dyspepsia (discussed in Chapter 23).

flatulence: the condition of having excessive intestinal gas, which causes abdominal discomfort.

Diarrhea

Diarrhea is characterized by the passage of frequent, watery stools. In most cases, it lasts for only a day or two and subsides without complication. Severe or persistent diarrhea, however, can cause dehydration and electrolyte imbalances. If chronic, it may lead to weight loss and malnutrition. Serious cases of diarrhea are often accompanied by other symptoms such as fever, cramps, dyspepsia, or bleeding, which help in diagnosing the cause.

Causes of Diarrhea Diarrhea is a complication of many different medical conditions and may also be induced by infections, medications, or dietary substances. It results from inadequate fluid reabsorption in the intestines, sometimes in conjunction with an increase in intestinal secretions.[6] Most cases of diarrhea are categorized as *osmotic* or *secretory.* In *osmotic diarrhea,* unabsorbed nutrients or other substances attract water to the colon and increase fecal water content; the usual causes include lactase deficiency, high intakes of poorly absorbed sugars (such as sorbitol, mannitol, or fructose), and ingestion of laxatives that contain magnesium or phosphates. In *secretory diarrhea,* the fluid secreted by the intestines exceeds the amount that can be reabsorbed by intestinal cells. Secretory diarrhea is often due to bacterial food poisoning but can also be caused by various chemical substances and inflammatory conditions. Motility disorders can also cause diarrhea: rapid transit within the colon shortens the contact time needed for fluid reabsorption, whereas slow transit can promote bacterial overgrowth (discussed in a later section) and thereby alter intestinal secretions.[7]

Acute cases of diarrhea start abruptly and may persist for several weeks; they are frequently caused by viral, bacterial, or protozoal infections or occur as a side effect of medications. Chronic diarrhea, which persists for a month or longer, can result from altered GI tract motility, intestinal inflammation, malabsorptive and endocrine disorders, infectious diseases, radiation treatment, and many other conditions. As mentioned in earlier chapters, diarrhea is a frequent complication of tube feedings or may occur when enteral feedings are resumed after a period of bowel rest (see Chapters 20 and 21).

Medical Treatment of Diarrhea Correcting the underlying medical disorder is the first step in treating diarrhea. For example, antibiotics are prescribed for treat-

ing infections. If a medication causes diarrhea, a different drug may be prescribed. If certain foods are responsible, they can be omitted from the diet. Bulk-forming agents such as psyllium (Metamucil) or methylcellulose (Citrucel) can help to reduce the liquidity of the stool. If chronic diarrhea does not respond to treatment, antidiarrheal drugs may be prescribed to slow GI motility or reduce intestinal secretions. Probiotics ◆ may be beneficial for certain types of diarrhea (especially diarrhea caused by infections), but standard treatment protocols have not been developed.[8] People with severe, **intractable** diarrhea sometimes require total parenteral nutrition.

◆ *Probiotics* are live bacteria provided in foods and dietary supplements for the purpose of preventing or treating disease. Highlight 24 describes the potential health benefits of probiotics.

Oral Rehydration Therapy Severe diarrhea necessitates the replacement of lost fluid and electrolytes. Oral rehydration solutions can be purchased or easily mixed using water, salts, and glucose or sucrose (see the recipe in the margin). ◆ The addition of carbohydrate to the rehydration solution facilitates sodium and water absorption. Commercial sports drinks are not recommended for rehydration because their sodium contents are too low to replace losses resulting from severe diarrhea; they can be used if accompanied by salty snack foods, however.[9] When diarrhea results in extreme dehydration, intravenous solutions are used to quickly replenish fluid and electrolytes.

◆ An oral rehydration solution can be mixed from the following ingredients:
- $\frac{1}{2}$ tsp sodium chloride (table salt)
- $\frac{1}{3}$ tsp potassium chloride (salt substitute)
- $\frac{3}{4}$ tsp sodium bicarbonate (baking soda)
- $1\frac{1}{3}$ tbs sugar
- 1 qt water

Nutrition Therapy for Diarrhea Because diarrhea can develop for numerous reasons, the nutrition prescription depends on the medical diagnosis and severity of the condition. The dietary treatment often recommended is a low-residue, low-fat, lactose-free diet.[10] The low-residue diet limits foods that contribute to colonic residue, such as those with significant amounts of fiber, resistant starch, lactose (in lactose-intolerant individuals), fructose, and sugar alcohols. Fructose and sugar alcohols, which are poorly absorbed, retain fluids in the colon and contribute to osmotic diarrhea. Similarly, milk products may worsen osmotic diarrhea in persons who are lactose intolerant. Avoidance of fatty foods is recommended because they can sometimes aggravate diarrhea. Gas-producing foods can increase intestinal distention and cause additional discomfort. Patients should avoid coffee and tea because caffeine stimulates GI motility and can thereby reduce water reabsorption. In the treatment of formula-fed infants, apple pectin or banana flakes are sometimes added to formulas to help thicken stool consistency. Table 24-3 lists examples of foods that may worsen diarrhea, although individual tolerances vary.

intractable: not easily managed or controlled.

TABLE 24-3 Foods That May Worsen Diarrhea

Foods to Avoid	Rationale	Selected Examples
High-fiber foods	They increase colonic residue.	Breads and cereals with more than 2 g fiber per serving, fruits and vegetables with peels or skins.
Foods with indigestible carbohydrates	They contribute to osmotic diarrhea.	Artichokes, asparagus, brussels sprouts, cabbage, dried beans and peas, fruit, garlic, green beans, leeks, onions, wheat, zucchini.
Foods that contain fructose or sugar alcohols	They contribute to osmotic diarrhea.	Dried fruits, fresh fruits (except bananas), fruit juices, fructose-sweetened soft drinks, sugar-free gums and candies.
Milk products, if person is lactose intolerant	They contribute to osmotic diarrhea.	Milk and milk products.
Gas-producing foods	They increase abdominal discomfort.	Foods with poorly digested or absorbed carbohydrates (including foods listed in the three categories directly above).
Caffeine-containing beverages	They increase intestinal motility.	Coffee, tea, colas, energy drinks.

[a]Individual tolerances vary; the foods to avoid are best determined by trial and error.

Gibson, Clinical ramifications of malabsorption of fructose and other short-chain carbohydrates, *Practical Gastroenterology* (August 2007): 51–65; M. H. Beers and coeditors, *The Merck Manual of Diagnosis and Therapy* (Whitehouse Station, N.J.: Merck Research Laboratories, 2006), pp. 77–80.

IN SUMMARY

The most common intestinal problems include constipation, intestinal gas, and diarrhea. Constipation accompanies a wide range of conditions but generally correlates with low-fiber diets, low food intake, and physical inactivity. Intestinal gas is largely produced by bacteria that colonize the colon and is often associated with nutrient malabsorption. Diarrhea can result from intestinal infections, malabsorption, motility disorders, medications, or dietary substances and may require oral rehydration therapy to replace fluid and electrolyte losses. Dietary modifications may help to improve bowel function and alleviate intestinal discomfort.

TABLE 24-4 Potential Causes of Malabsorption

Genetic disorders
- Enzyme deficiencies

Pancreatic disorders
- Chronic pancreatitis
- Cystic fibrosis

Intestinal disorders
- Bacterial overgrowth
- Celiac disease
- Crohn's disease
- HIV enteropathy
- Radiation enteritis

Intestinal infections
- AIDS-related infections
- Giardiasis

Liver disease (bile insufficiency)

Surgeries
- Gastric bypass surgery
- Intestinal bypass surgery
- Intestinal resection (short bowel syndrome)

Malabsorption Syndromes

To digest and absorb nutrients, we depend on normal digestive secretions and healthy intestinal mucosa. Disorders of the pancreas that cause enzyme deficiencies can impair nutrient digestion and lead to widespread malabsorption. Intestinal inflammation, certain medications, and cancer therapies can damage mucosal tissue and interfere with its absorptive functions. In some cases, the treatment of an intestinal disorder requires surgical removal of a section **(resection)** of the small intestine, leaving minimal absorptive capacity in the portion that remains. Table 24-4 lists examples of diseases and treatments that are frequently associated with malabsorption.

Malabsorption rarely involves a single nutrient. When malabsorption is caused by pancreatic enzyme deficiencies, all macronutrients—protein, carbohydrate, and fat—may be affected. If fat is malabsorbed, essential fatty acids, fat-soluble vitamins, and minerals are usually malabsorbed as well. Malabsorptive disorders and their treatments can further tax nutrition status by causing complications that alter food intake, raise nutrient needs, and incur additional nutrient losses.

Fat Malabsorption

Fat is the nutrient most frequently malabsorbed, because both digestive enzymes and bile must be present for its digestion. Thus, fat malabsorption often develops when an illness interferes with the production or secretion of either pancreatic lipase or bile. For example, pancreatitis and cystic fibrosis can decrease the secretion of pancreatic lipase, whereas severe liver disease can reduce bile availability. Fat malabsorption also results from conditions that damage the intestinal mucosa, such as inflammatory bowel diseases or radiation treatment for cancer. Motility disorders that cause rapid gastric emptying or rapid intestinal transit can also lead to fat malabsorption because they prevent the normal mixing of dietary fat with lipase and bile.

Fat malabsorption is often evidenced by **steatorrhea,** the presence of excessive fat in the stools. Steatorrhea can be evaluated by performing a 72-hour fecal collection and measuring the stool's fat content. In healthy individuals, the fecal fat excretion is generally less than 7 grams per day, although diarrhea can raise the fecal fat output to up to 14 grams per day.[11]

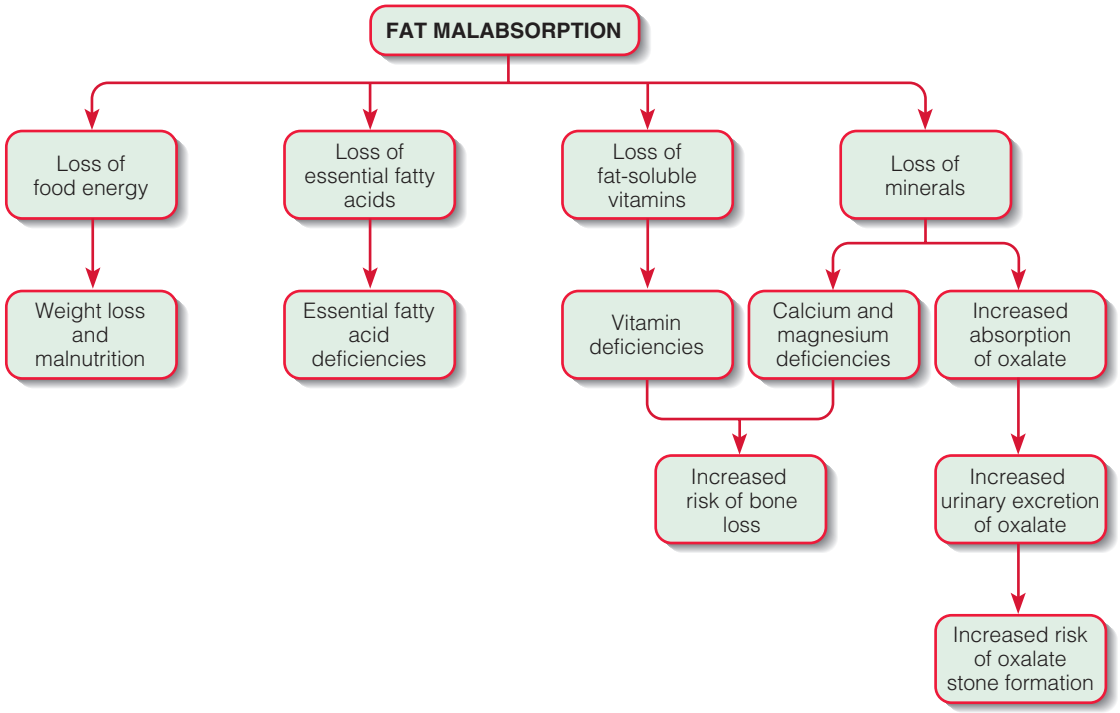
Consequences of Fat Malabsorption Fat malabsorption is associated with losses of food energy, essential fatty acids, fat-soluble vitamins, and some minerals (see Figure 24-2). Weight loss is possible unless the individual consumes alternative sources of energy. Deficiencies of fat-soluble vitamins and essential fatty acids are common in chronic conditions. Malabsorption of some minerals, including calcium, magnesium, and zinc, often develops because the minerals form **soaps** with unabsorbed fatty acids and bile acids. Calcium deficiency can lead to bone loss, which is further aggravated by the vitamin D deficiency that is common in cases of fat malabsorption.

resection: the surgical removal of part of an organ or body structure.

steatorrhea (stee-AT-or-REE-ah): excessive fat in the stools resulting from fat malabsorption; characterized by stools that are loose, frothy, and foul smelling due to a high fat content.
- **steat** = fat
- **rheo** = flow

soaps: chemical compounds that form between fatty acids and positively charged minerals.

FIGURE 24-2 The Consequences of Fat Malabsorption



Another consequence of fat malabsorption is an increased risk of kidney stones, which are most often composed of calcium oxalate. ◆ The oxalates in foods ordinarily bind to calcium in the small intestine and are excreted in the stool. If calcium instead binds to fatty acids or bile acids, oxalates are free to be absorbed into the blood and are ultimately excreted in the urine. The risk of developing oxalate stones increases when urinary oxalate levels are high. Kidney stones are discussed further in Chapter 28.

◆ Reminder: *Oxalates* are plant compounds that bind with some minerals to form complexes that the body cannot absorb. They are present in green leafy vegetables such as beet greens and spinach.

Dietary Adjustments If steatorrhea does not improve, a fat-restricted diet may be recommended (see Table 24-5 on p. 762). The objectives of fat restriction are to relieve intestinal symptoms that are aggravated by fat intake (usually diarrhea and flatulence) and to reduce vitamin and mineral losses. Fat should not be restricted more than necessary because fat is an important source of energy. Medium-chain triglycerides (MCT), which do not require lipase or bile for digestion and absorption, can be used as an alternative source of dietary fat (although MCT oil does not provide essential fatty acids). The "How to" on p. 763 offers suggestions for following a fat-restricted diet and for using MCT oil.

Bacterial Overgrowth

Ordinarily, the stomach and small intestine are protected from **bacterial overgrowth** by gastric acid, which destroys bacteria, and by peristalsis, which flushes bacteria through the small intestine before they multiply.[12] When bacterial overgrowth does occur, it disrupts fat digestion and absorption, because excessive bacteria in the small intestine dismantle the bile acids needed for fat emulsification. Consequently, deficiencies of the fat-soluble vitamins may eventually develop. The bacteria also compete for vitamin B_{12}, impairing its absorption and increasing the risk of vitamin B_{12} deficiency. Although symptoms of bacterial overgrowth are often minor and nonspecific, severe cases may lead to chronic diarrhea, steatorrhea, abdominal discomfort, bloating, and weight loss.

bacterial overgrowth: excessive bacterial colonization of the stomach and small intestine; may be caused by low gastric acidity, altered gastrointestinal motility, mucosal damage, or contamination.

TABLE 24-5 Fat-Restricted Diet

General guidelines	*For fat restriction of 25 grams per day:* Limit meat and meat alternates to 4 ounces daily (cooked weight); limit fat equivalents to 1 per day (see Fats section below). *For fat restriction of 50 grams per day:* Limit meat and meat alternates to 6 ounces daily (cooked weight); limit fat equivalents to 3 to 5 per day. *To raise fat content:* Allow additional servings of meat or fat. *To lower fat content:* Restrict servings of meat or fat.
Meat and meat alternates	*Recommended:* Choose lean meat, fish, and poultry only. Preparation methods can include broiling, roasting, grilling, or boiling. Trim visible fat and remove poultry skin before consuming. For sandwiches, select turkey breast or other low-fat luncheon meats. Limit eggs to 2 per week or use low-fat egg substitutes. Meat alternates include tofu and dried beans and peas. *Avoid:* Pork and beans, sausage, bacon, frankfurters, spareribs, duck, goose, tuna packed in oil, fried meats.
Milk and milk products	Choose milk products that contain less than 1 gram fat per serving. *Recommended:* Fat-free milk, fat-free yogurt, fat-free sour cream substitutes, fat-free half-and-half and cream substitutes, fat-free cheeses. *Avoid:* Milk products that are not fat-free.
Breads, cereals, rice, and pasta	Choose breads, cereals, rice, and pasta dishes that contain less than 1 gram fat per serving. *Recommended:* Whole-grain breads, soda crackers, cooked cereals and most cold cereals, plain tortillas, bagels, English muffins, fat-free muffins, graham crackers, plain rice, plain noodles and pasta. *Avoid:* Biscuits, pancakes, waffles, doughnuts, granola, snack crackers that contain fat, corn chips, cornbread, fried rice, pasta sauces with added fats.
Vegetables	Choose vegetables that contain less than 1 gram fat per serving. *Recommended:* All vegetables prepared without added fats. *Avoid:* Buttered or fried vegetables, creamed vegetables, au gratin style, french-fried potatoes, olives, sauces with added fats.
Fruit	Choose fruits that contain less than 1 gram fat per serving. *Recommended:* All fruits prepared without added fats. *Avoid:* Avocado, fruit dips made with fat or coconut.
Desserts	Choose desserts that contain less than 1 gram fat per serving. *Recommended:* Sherbet, fruit ices, fruit whips, flavored gelatin, angel food cake, meringues, fat-free puddings, fat-free baked products, fat-free ice cream or frozen yogurt, fat-free candies (marshmallows, jelly beans, hard candy). *Avoid:* Cakes, cookies, pies, and pastries made with fat; puddings made with whole milk or eggs; ice cream; candies made with fat (caramel, chocolates).
Fats	Choose 1 fat equivalent daily if fat restriction is 25 grams per day, and 3 to 5 fat equivalents daily if fat restriction is 50 grams per day. *One fat equivalent is equal to:* Vegetable oil: 1 tsp. Butter, margarine: 1 tsp, or 1 tbs diet margarine. Mayonnaise: 1 tsp, or 1 tbs reduced-kcalorie mayonnaise. Salad dressing: 1 tbs, or 2 tbs reduced-kcalorie dressing. Nuts: 6 almonds or cashews, 10 peanuts, 2 tsp peanut butter, 4 halves walnuts or pecans.
Beverages	Choose beverages that contain less than 1 gram fat per serving. *Recommended:* Coffee, tea, soft drinks, juices, fat-free milk, coffee substitutes. *Avoid:* Beverages made with milk (unless fat-free milk) or added cream, chocolate milk, eggnog, milk shakes.

SOURCE: Adapted from American Dietetic Association, *Manual of Clinical Dietetics* (Chicago: American Dietetic Association, 2000), pp. 697–702.

Causes of Bacterial Overgrowth Conditions that impair intestinal motility and allow material to stagnate can increase susceptibility to bacterial overgrowth. For example, in some types of gastric surgery, a portion of the small intestine is bypassed, preventing the flow of material in the bypassed region and allowing bacteria to flourish (see the "blind loop" shown in Figure 23-3 on p. 742). Intestinal motility can also be reduced by strictures, obstructions, and diverticula (protrusions) in the small intes-

HOW TO Follow a Fat-Restricted Diet

Fat-restricted diets can be difficult to follow. Fats add flavors, aromas, and textures to foods—characteristics that make foods more enjoyable. Unlike some diets that can be introduced gradually, a fat-restricted diet is often implemented immediately, allowing little time for adaptation. These suggestions may help:

- Fat is better tolerated if provided in small portions. Divide the day's allotment into several servings that can be consumed throughout the day.
- Use variety to enhance enjoyment of meals: vary flavors, textures, colors, and seasonings.
- Look for fat-free items when grocery shopping. Incorporate fat-free ingredients when preparing favorite recipes.
- Try fat-free and low-fat condiments to improve the diet's palatability. Experiment with herbs and spices. Instead of butter, use fruit butters on toast. Use butter-flavored granules on vegetables. Replace mayonnaise on sandwiches with spicy mustard. Replace salad dressings with flavored vinegars.
- Avoid products that contain the fat substitute olestra, which may aggravate GI symptoms.

If patients are interested in using MCT oil:

- Explain that MCT products are expensive, but that the cost is sometimes covered by medical insurance.
- Advise patients to add MCT oil to the diet gradually. Diarrhea and abdominal cramps may result if too much is used at once. Tolerance to MCT oil may improve in time.
- Advise patients that MCT oil may have an unpleasant taste when used alone. Suggest using MCT oil in recipes as a substitute for regular oil. MCT oil can replace oil in salad dressings, be incorporated into sauces, and be used in cooking or baking. It can also be added to fat-free milk products to make milk shakes.
- Point out that MCT oil should not be used to fry foods because it decomposes at lower temperatures than most cooking oils.

NOTE: MCT = medium-chain triglyceride.

tine, as well as by chronic diseases such as diabetes mellitus, scleroderma, and chronic kidney disease.[13]

Reduced secretions of gastric acid can also lead to bacterial overgrowth. Possible causes include atrophic gastritis, acid-suppressing medications, and acid-reducing surgery (vagotomy) for peptic ulcer disease.

Treatment for Bacterial Overgrowth Treatment may include antibiotics to suppress bacterial growth and surgical correction of the anatomical defects that contribute to a motility disorder. Medications may be given to stimulate peristalsis. Dietary supplements are provided to correct nutrient deficiencies, especially deficiencies in the fat-soluble vitamins A, D, and E; calcium; and vitamin B_{12}.

IN SUMMARY

Malabsorption syndromes can be caused by reduced digestive secretions or damaged intestinal mucosa. Malabsorption usually affects multiple nutrients and causes complications that impair nutrition status further. Fat malabsorption, usually indicated by the development of steatorrhea, is associated with the loss of food energy and deficiencies of essential fatty acids, fat-soluble vitamins, and some minerals. Bacterial overgrowth can result from impaired peristalsis or reduced gastric acidity and typically causes malabsorption of fat and vitamin B_{12}.

Conditions Affecting the Pancreas

As mentioned previously, pancreatic disorders can lead to maldigestion and malabsorption due to the impaired secretion of digestive enzymes. ◆ This section describes several pancreatic illnesses that are characterized by widespread malabsorption.

◆ Reminder: The digestive secretions of the pancreas include bicarbonate and digestive enzymes. The bicarbonate neutralizes the acidic gastric contents that enter the duodenum, and the digestive enzymes break down protein, carbohydrate, and fat.

Pancreatitis

Pancreatitis is an inflammatory disease of the pancreas. The inflammation causes damage to pancreatic tissue and the release of active pancreatic enzymes, which may destroy the surrounding tissues. Although mild cases may subside in a few days, other cases can persist for weeks or months. Chronic pancreatitis can lead to irreversible damage to pancreatic tissue and permanent loss of function.

Acute Pancreatitis Acute pancreatitis is short-lived and does not cause permanent damage. It is most often caused by gallstones or excessive alcohol use—factors that account for more than 70 percent of acute cases.[14] Less common causes include hypertriglyceridemia (triglyceride concentrations higher than 1000 milligrams per deciliter), exposure to toxins, and the use of some medications.

Common symptoms include severe abdominal pain, nausea and vomiting, and abdominal distention. Elevated serum levels of amylase and lipase—released by damaged pancreatic tissue into the blood—help to confirm the diagnosis. In most patients, the condition resolves within a week with no complications. More severe cases may lead to renal failure, sepsis, and other complications that often require prolonged hospitalization.

Nutrition Therapy for Acute Pancreatitis Oral fluids and food are withheld until pain and tenderness have subsided, and fluids and electrolytes are supplied intravenously. After three to seven days, patients may be able to consume small amounts ($^1/_2$ to 1 cup) of fluids; either zero-kcalorie fluids or clear liquids may be provided initially.[15] If tolerated, the diet progresses from liquid feedings to solid foods, given in small, frequent feedings. Because fat stimulates the pancreas more than other nutrients, a low-fat diet may be better tolerated at first. In severe pancreatitis, jejunal tube feedings are sometimes necessary; either standard formulas or elemental formulas ◆ may be used, depending on patient tolerance.[16] Protein and energy needs are high in severe cases due to the catabolic and hypermetabolic effects of inflammation.

◆ Reminder: An *elemental formula* contains hydrolyzed nutrients that require minimal digestion and are easily absorbed.

Chronic Pancreatitis Chronic pancreatitis is characterized by permanent damage to pancreatic tissue, resulting in impaired secretion of digestive enzymes. About 70 to 90 percent of chronic pancreatitis cases are caused by excessive alcohol consumption.[17] Unlike acute pancreatitis, chronic pancreatitis is not caused by gallstones. In children, most cases are attributable to cystic fibrosis, discussed in a later section.

In chronic pancreatitis, the abdominal pain is often severe and unrelenting and worsens with eating. Analgesics or opiate drugs are often needed for pain control. Fat maldigestion develops sooner than maldigestion of protein or carbohydrate, and steatorrhea is common in advanced cases. Food avoidance (due to pain associated with eating) and malabsorption may lead to weight loss and malnutrition. Advanced cases are associated with reductions in both insulin and glucagon secretions, and diabetes eventually develops in up to 80 percent of patients.[18]

Nutrition Therapy for Chronic Pancreatitis The objectives of nutrition therapy are to improve nutrition status, reduce malabsorption, and prevent symptom recurrence. Protein and energy needs are high in patients who have lost weight or are malnourished. Dietary supplements are often needed to correct nutrient deficiencies, which may be due to malabsorption or to the alcohol abuse that caused the disease. Patients must avoid alcohol completely because it can worsen pancreatic function.[19]

Steatorrhea is usually treated with pancreatic enzyme replacement.[20] Pancreatic enzymes are often **enteric coated** to resist the acidity of the stomach and do not dissolve until the pH is above 5.5. If nonenteric-coated preparations are used, acid-suppressing drugs may be required. Fecal fat concentrations are monitored to determine if the enzyme treatment has been effective. A low-fat diet may be necessary if steatorrhea is resistant to treatment, in which case medium-chain triglycerides can be used to replace other fat sources. The accompanying Case Study allows you to apply your knowledge of chronic pancreatitis to a clinical situation.

enteric coated: refers to medications or enzyme preparations that can withstand gastric acidity and dissolve only at a higher pH.

CASE STUDY Retired Executive with Chronic Pancreatitis

Taylor Gray is a 62-year-old man with chronic pancreatitis. He was forced to resign his position as president of an import-export company in his early 50s, when his problems with alcohol and declining health seriously impaired his abilities to run the company. His wife divorced him shortly thereafter, and he currently lives alone.

At 5 feet 11 inches tall, Mr. Gray weighs 145 pounds. He continues to experience frequent, severe abdominal pain and steatorrhea. Mr. Gray has been advised to follow a high-kcalorie, high-protein diet with no fat restrictions and uses enzyme replacement with meals, but he has difficulty eating enough food. He has not used alcohol for 8 months. Mr. Gray takes pain medications, acid-suppressing drugs, and a multivitamin daily.

1. What are the possible reasons for Mr. Gray's difficulty maintaining weight? What suggestions may help? Why was he advised to consume a high-protein diet?
2. Explain why malabsorption develops in chronic pancreatitis. Which nutrients are most likely to be affected?
3. How can Mr. Gray's physician determine whether the enzyme replacement therapy is effective? Explain why Mr. Gray must continue to use acid suppressants.
4. If Mr. Gray continues to experience steatorrhea, what measures would you suggest? What complications may develop if the steatorrhea is not controlled?

Cystic Fibrosis

Cystic fibrosis is the most common life-threatening genetic disorder among Caucasians, with an incidence of approximately 1 in 2000 to 1 in 3000 white births. In the United States, about 30,000 people are affected.[21] Cystic fibrosis is caused by a genetic mutation that disturbs the transport of chloride ions in **exocrine** glands. This defect results in thickened glandular secretions and a broad range of serious complications. Until a few decades ago, few infants born with cystic fibrosis survived to adulthood. Now, with early detection and advances in medical treatment, the average life span has extended beyond 30 years of age, with many patients surviving into their 50s.[22]

Consequences of Cystic Fibrosis Cystic fibrosis is characterized by abnormal chloride and sodium levels in exocrine secretions. The secretions are unusually viscous and can obstruct the ducts that normally allow their passage. The blockages that develop can disrupt tissue function and cause tissue damage. The major complications of cystic fibrosis involve the lungs, pancreas, ◆ and sweat glands:

- *Lung disease.* The abnormally thick mucus secretions cause obstructions in many of the small airways of the lungs. The obstructions lead to chronic coughing and persistent respiratory infections, both of which contribute to progressive inflammation in the bronchial tissues. The lung damage that eventually develops results in breathing difficulties and lower exercise tolerance. As with other obstructive airway diseases, ◆ in cystic fibrosis nutrition status becomes impaired due to hypermetabolism, the greater energy cost of labored breathing, and anorexia (loss of appetite). The chronic respiratory infections raise energy needs further.
- *Pancreatic disease.* Approximately 85 percent of cystic fibrosis patients develop thickened pancreatic secretions that obstruct the pancreatic ducts, causing digestive enzymes to accumulate in the pancreas and destroy pancreatic tissue. Fewer pancreatic enzymes reach the small intestine, leading to malabsorption of protein, fat, and fat-soluble vitamins. Other problems that may develop over time include pancreatitis, hyperglycemia (due to destruction of the insulin-producing cells), and diabetes.[23]
- *Other complications.* Because cystic fibrosis affects all exocrine secretions, complications typically develop in many other tissues or organs. Salt losses in sweat are usually excessive, increasing the risk of dehydration. Intestinal

◆ Reminder: The pancreas secretes digestive enzymes and bicarbonate into the digestive tract (*exocrine* secretions) and the hormones insulin and glucagon into the bloodstream (*endocrine* secretions).

◆ Chapter 22 describes the nutrition problems associated with chronic obstructive lung diseases.

cystic fibrosis: an inherited disease characterized by the presence of abnormally viscous exocrine secretions; often leads to respiratory illness and pancreatic insufficiency.

exocrine: pertains to external secretions, such as those of the mucous membranes or the skin. Opposite of *endocrine,* which pertains to hormonal secretions into the blood.
- **exo** = outside
- **krinein** = to secrete

Postural drainage, a type of physical therapy used in treating cystic fibrosis, helps to clear the thick, sticky secretions that block airways and increase infection risk.

obstruction is a common symptom in newborn infants and may also occur in older patients. Gallbladder and liver diseases may result from bile duct obstructions. Abnormalities in genital tissues cause sterility in men and reduced fertility in women.

Nutrition Therapy for Cystic Fibrosis Children with cystic fibrosis are chronically undernourished, grow poorly, and have difficulty maintaining normal body weight. Their energy and protein needs are high due to increased requirements, nutrient malabsorption, and reduced food consumption. To achieve normal growth, energy intakes should be 20 to 50 percent higher than DRI values, and protein should provide 15 to 20 percent of kcalories.[24] To compensate for fat malabsorption, about 35 to 40 percent of kcalories should come from fat. A patient with cystic fibrosis is therefore encouraged to consume high-kcalorie and high-fat foods, eat frequent meals and snacks, and supplement meals with milk shakes or liquid dietary supplements. Supplemental tube feedings can help to improve nutrition status if energy intakes are inadequate.

Pancreatic enzyme replacement therapy is a central feature of cystic fibrosis treatment. Supplemental enzymes must be included with every meal or snack. For infants and small children, the contents of capsules are mixed in small amounts of liquid or a soft food (such as applesauce) and fed with a spoon. Enzyme dosages may need to be adjusted if malabsorption continues, as evidenced by poor growth or GI symptoms such as steatorrhea, intestinal gas, or abdominal pain.

The risk of nutrient deficiency depends on the degree of malabsorption. The nutrients of greatest concern include the fat-soluble vitamins, essential fatty acids, and calcium. Multivitamin and fat-soluble vitamin supplements are routinely recommended. The liberal use of table salt and salty foods is encouraged to make up for losses of sodium in sweat. The accompanying Case Study checks your understanding of the nutrition therapy for a child with cystic fibrosis.

IN SUMMARY

Chronic pancreatic disorders can lead to widespread maldigestion and malabsorption due to impaired secretion of digestive enzymes. Acute pancreatitis is short-lived and does not cause permanent damage, but it requires that food and liquids be withheld until healing has occurred. Chronic pancreatitis, most often caused by alcohol abuse, results in digestive enzyme deficiencies and requires pancreatic enzyme replacement therapy. Cystic fibrosis, a genetic disorder associated with thickened exocrine secretions, causes obstructive lung disease and pancreatic damage. Children with cystic fibrosis have high protein and energy requirements and must use pancreatic enzyme replacement therapy and dietary supplements to reverse malnutrition.

CASE STUDY Child with Cystic Fibrosis

Julie is a 7-year-old girl diagnosed with cystic fibrosis. Symptoms of steatorrhea and failure to gain weight in infancy prompted the tests that led to the diagnosis. She is currently 45 inches tall and weighs 42 pounds. Her height for age and weight for age fall near the 10th percentile (see Appendix E). Julie eats regular foods during the day and receives additional nutrients by tube feedings delivered overnight.

1. What do the height and weight percentiles tell you about Julie's nutrition status? Why is growth failure common in children with cystic fibrosis?
2. Explain why Julie's energy needs are so much higher than normal. Describe the elements of the diet that Julie should follow to gain weight. Would her energy requirements change if she developed a respiratory infection?
3. Explain to Julie's parents how to use enzyme replacement therapy effectively.
4. Julie's parents are hoping to discontinue the nightly tube feedings. Do you think the tube feedings are necessary? Why or why not?

Conditions Affecting the Small Intestine

When the intestinal mucosa is damaged due to inflammation, infection, or other causes, malabsorption is the likely outcome. This section discusses *celiac disease* and *inflammatory bowel diseases* (intestinal conditions that can impair mucosal function) and *short bowel syndrome* (the malabsorptive condition that results when a substantial portion of the small intestine is surgically removed).

Celiac Disease

Celiac disease is an immune disorder characterized by an abnormal immune response to a protein fraction in **wheat gluten** ◆ and to related proteins in barley and rye. The reaction to gluten causes severe damage to the intestinal mucosa and subsequent malabsorption. Celiac disease may affect as many as 1 in every 133 persons in the United States.[25]

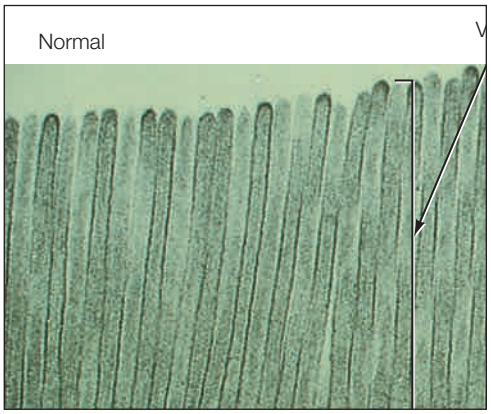
◆ The protein in wheat gluten that has toxic effects in celiac disease is called *gliadin.*

◆ Reminder: *Crypts* are tubular glands that lie between the intestinal villi and secrete intestinal juices into the small intestine.

Consequences of Celiac Disease The immune reaction to gluten can cause striking changes in intestinal tissue. In affected areas, the absorptive surface appears flattened due to the shortening or absence of villi and overdeveloped crypts (see the photos). ◆ The reduction in mucosal surface area (and, therefore, in intestinal digestive enzymes) can be substantial. The damage may be restricted to the duodenum or may involve the full length of the small intestine. Individuals with severe disease may malabsorb all nutrients to some degree, especially the macronutrients, fat-soluble vitamins, electrolytes, calcium, magnesium, zinc, iron, folate, and vitamin B_{12}.[26] As a result of nutrient deficiencies, patients often develop anemia and have low bone mineral density.

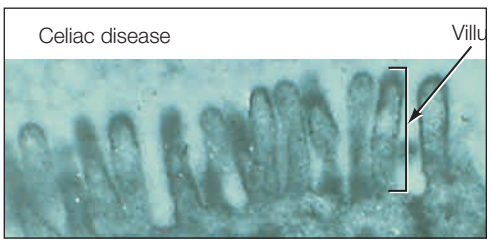
Symptoms of celiac disease include GI disturbances such as diarrhea, steatorrhea, and flatulence. Because lactase deficiency can result from mucosal damage, the GI symptoms may be exacerbated by milk products. Children with celiac disease often have stunted growth and are severely underweight. Adults may develop bone disorders and have fertility problems. Individuals with celiac disease who do not eliminate gluten from the diet are at increased risk of developing intestinal and lymphatic cancers.[27]

Some gluten-sensitive individuals may have few GI symptoms but react to gluten by developing a severe rash. This condition is called **dermatitis herpetiformis** and requires dietary adjustments similar to those for celiac disease.



© Medcom, Inc.

In the healthy intestine, the villi greatly increase the absorptive surface area.



© Medcom, Inc.

In celiac disease, the villi may be shortened or absent, resulting in substantial reductions in nutrient absorption.

Nutrition Therapy for Celiac Disease The treatment for celiac disease is lifelong adherence to a gluten-free diet. Improvement in symptoms is often evident within several weeks, although mucosal healing can sometimes take years. If lactase deficiency is suspected, patients should avoid lactose-containing foods until the intestine has recovered. Dietary supplements can be used to meet micronutrient needs and reverse deficiencies.[28]

The gluten-free diet eliminates foods that contain wheat, barley, and rye (see Table 24-6 on p. 768). Because many foods contain ingredients derived from these grains, foods that are problematic are not always obvious. Even small amounts of gluten may cause symptoms in some persons, so patients should carefully check ingredient lists on food labels. Gluten-containing products that may be overlooked include beer, caramel coloring, coffee substitutes, communion wafers, imitation meats, malt syrup, medications, salad dressings, and soy sauce. Special gluten-free products can be purchased to replace common food items such as bread, pasta, and cereals. Although somewhat expensive, these foods increase food choices and allow celiac patients to enjoy foods that would otherwise be forbidden.

Although most people with celiac disease can safely consume moderate amounts of oats, oats grown in the United States may be contaminated with wheat, barley, or rye.[29] Oats are often grown in rotation with other grains and may

celiac (SEE-lee-ack) **disease:** a condition characterized by an abnormal immune reaction to wheat gluten that causes severe intestinal damage and nutrient malabsorption; also called *gluten-sensitive enteropathy* or *celiac sprue.*

wheat gluten (GLU-ten): a family of water-insoluble proteins in wheat; includes the gliadin (GLY-ah-din) proteins that are toxic to persons with celiac disease.

dermatitis herpetiformis (DERM-ah-TYE-tis HER-peh-tih-FOR-mis): a gluten-sensitive disorder characterized by a severe skin rash.

TABLE 24-6 Gluten-Free Diet

Meat and meat alternates	• *Recommended:* Fresh, frozen, salted, and smoked meats (unless processed meats contain any prohibited grains); products made with hydrolyzed vegetable protein (HVP) or hydrolyzed plant protein (HPP); eggs; dried beans and peas; tofu. • *Questionable:* Luncheon meats, sandwich spreads, meat loaf, frozen burgers, sausage, imitation meat products, meat extenders, egg substitutes, dried egg products, dry-roasted nuts, peanut butter. • *Avoid:* Products that are breaded or prepared in cream sauces, gravies.
Milk and milk products	• *Recommended:* Milk, buttermilk, plain yogurt, cheese. • *Questionable:* Milk shakes, cheese spreads, flavored yogurt, frozen yogurt, chocolate milk. • *Avoid:* Malted milk and malted milk powders.
Breads, cereals, rice, and pasta	• *Recommended:* Breads, baked products, and cereals made with corn, rice, soy, potato starch, potato flour, hominy, buckwheat, millet, teff, sorghum, amaranth, quinoa, arrowroot, and tapioca; pasta and noodles made with grains or starches listed above; corn tacos and corn tortillas. • *Questionable:* Oatmeal and oat bran; rice crackers, rice cakes, and corn cakes. • *Avoid:* Breads, baked products, cereals, tortillas, or pastas made with wheat, rye, barley, triticale, spelt, kamut, wheat germ, wheat bran, graham flour, durum flour, wheat starch, bulgur, farina, or semolina from wheat; commercially prepared mixes for biscuits, cornbread, muffins, pancakes, or waffles; malt and malt flavoring; pretzels; matzos.
Fruits and vegetables	• *Recommended:* Any unprocessed fruits or vegetables. • *Questionable:* French fries, especially in fast-food restaurants; commercial salad dressings; fruit pie fillings; dried fruits. • *Avoid:* Scalloped potatoes (with wheat flour), creamed vegetables, vegetables dipped in batters.
Desserts	• *Recommended:* Ice cream, sherbet, egg custards, or gelatin desserts that do not contain gluten; pure baking chocolate; chocolate chips; hard candy. • *Questionable:* Icing, powdered sugar, candies, chocolate bars, marshmallows. • *Avoid:* Puddings thickened with wheat flour; ice cream or sherbets that contain gluten stabilizers; baked products or doughnuts made with wheat, rye, or barley; ice cream cones; licorice.
Beverages	• *Recommended:* Coffee; tea; cocoa; soft drinks; distilled alcoholic beverages such as rum, gin, whisky, and vodka; wine. • *Questionable:* Instant tea or coffee, coffee substitutes, chocolate drinks, hot cocoa mixes. • *Avoid:* Beer, ale, lager, malted beverages, cereal beverages (Postum), beverages that contain nondairy cream substitutes.

Gluten-free products help people with celiac disease enjoy a wider variety of foods.

Crohn's disease: an inflammatory bowel disease that usually occurs in the lower portion of the small intestine and the colon. Inflammation may pervade the entire intestinal wall.

ulcerative colitis (ko-LY-tis): an inflammatory bowel disease that involves the colon. Inflammation affects the mucosa and submucosa of the intestinal wall.

become contaminated during harvesting or processing. Although some oat millers have developed procedures that remove other grains from oats, no oats available in the United States are guaranteed to be gluten-free. Individuals who wish to try oats can be advised to limit their intakes to the amounts found to be safe (about $^1/_2$ cup of dry rolled oats per day) and to contact millers or product manufacturers to determine whether contamination with gluten-containing products is likely.[30]

A gluten-free diet may become monotonous unless care is taken to diversify food choices. The diet can also be a social liability by restricting food choices when individuals eat in restaurants, visit friends, or travel. Nonadherence is common when individuals are away from home.[31] Dietetic counseling may help celiac patients learn how to meet their nutrient needs and expand meal options despite dietary constraints.

Inflammatory Bowel Diseases

Inflammatory bowel diseases are chronic inflammatory disorders that damage gastrointestinal tissue. Both genetic and environmental factors are believed to contribute to the development of these diseases, but the exact triggers are unknown. Disease onset occurs most often in individuals between 15 and 25 years of age.[32]

Table 24-7 compares the two major forms of inflammatory bowel disease, **Crohn's disease** and **ulcerative colitis.** Crohn's disease usually involves the small intestine and may lead to nutrient malabsorption, whereas ulcerative colitis affects the colon, which is past the absorptive areas. Both diseases are characterized

TABLE 24-7 Comparison of Crohn's Disease and Ulcerative Colitis

	Crohn's Disease	Ulcerative Colitis
Location of inflammation	Approximately 40 percent of cases involve the ileum and cecum, 30 percent are in the small intestine only, and 25 percent are in the colon.	Inflammation is confined to the rectum and colon; it begins at the rectum and spreads into the colon.
Pattern of inflammation	Discrete areas separated by normal tissue ("skip" lesions).	Continuous inflammation that begins at the rectum and ends abruptly within the colon.
Depth of damage	Damage throughout all layers of tissue; causes deep fissures that give intestinal tissue a "cobblestone" appearance.	Damage primarily in the mucosa and submucosa.
Fistulas	Common.	Usually do not occur.
Cancer risk	Increased.	Greatly increased.

by periods of active disease interspersed with periods of remission. Nutrient losses can result from tissue damage, bleeding, and diarrhea.

Complications of Crohn's Disease Crohn's disease may occur in any region of the GI tract, but most cases involve the ileum and/or large intestine. Lesions may develop in different areas in the intestine, with normal tissue separating affected regions (called "skip" lesions). During exacerbations, the inflammation can extend deeply into intestinal tissue and be accompanied by ulcerations, fissures, and fistulas. ◆ Loops of intestine may become matted together. Scar tissue eventually thickens and stiffens the intestinal wall, narrowing the lumen and sometimes causing strictures or obstructions. About 60 to 75 percent of patients require surgical resections during the course of illness, although disease often recurs in the remaining intestine.[33] Patients with Crohn's disease are at increased risk of developing intestinal cancers.

◆ Reminder: *Fistulas* are abnormal passages between organs or tissues that permit the passage of fluids or secretions.

Malnutrition may result from malabsorption, nutrient losses (especially of protein) associated with the tissue damage, reduced food intake, and surgical resections that shorten the small intestine. If the ileum is affected, bile acids may become depleted. ◆ The result is malabsorption of fat, fat-soluble vitamins, calcium, magnesium, and zinc (the minerals bind to the unabsorbed fatty acids). Because the ileum is the site of vitamin B_{12} absorption, deficiency can develop unless the patient is given vitamin B_{12} injections. Anemia may result from bleeding, the inadequate absorption of nutrients involved in blood cell formation, or the metabolic effects of chronic illness (see Highlight 19). Anorexia develops due to abdominal discomfort and the effects of cytokines produced during the inflammatory process. [34]

◆ Reminder: Most of the bile used during digestion is eventually reabsorbed in the ileum and returned to the liver.

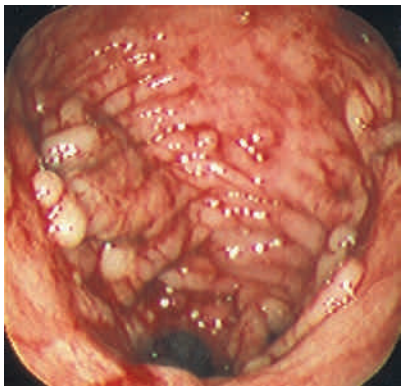
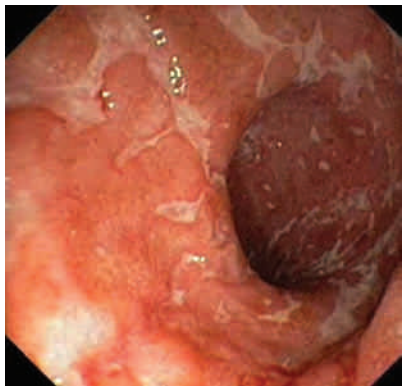
The healthy colon has a smooth surface with a visible pattern of fine blood vessels.



© Courtesy of the Crohn's and Colitis Foundation of America, Inc.

In Crohn's disease, the mucosa has a "cobblestone" appearance due to deep fissuring in the inflamed mucosal tissue.



© Hans Bjorknas/Gastrolab.net

In ulcerative colitis, the colon appears inflamed and reddened, and ulcers are visible.

Complications of Ulcerative Colitis Ulcerative colitis always involves the rectum and usually extends into the colon. Inflammation is continuous along the length of intestine affected, ending abruptly at the area where healthy tissue begins. Tissue erosion or ulceration develops primarily in the mucosa and submucosa (the top two layers of intestinal tissue). During active episodes, patients have frequent, urgent bowel movements that are small in volume. Stools are often streaked with blood and contain mucus.

Although mild disease may cause few complications, weight loss, fever, and weakness are common when most of the colon is involved. Severe disease is often associated with anemia (due to blood loss), dehydration, and electrolyte imbalances. Protein losses from the inflamed tissue can be substantial. A **colectomy** (removal of the colon) is performed in 20 to 25 percent of patients and prevents future recurrence.[35] Colon cancer risk is substantially increased in ulcerative colitis patients.

Drug Treatment of Inflammatory Bowel Diseases Medications help to reduce inflammation, control symptoms, and minimize complications. The drugs prescribed include antidiarrheal agents, immunosuppressants, anti-inflammatory drugs (usually corticosteroids and salicylates), and antibiotics. Although these medications may allow the patient to achieve and maintain remission, some may cause side effects that are detrimental to nutrition status. The Diet-Drug Interactions feature below lists some nutrition-related effects of the medications used in inflammatory bowel diseases.

Nutrition Therapy for Crohn's Disease In patients with Crohn's disease, dietary measures depend on the functional status of the GI tract and the symptoms and complications that develop; thus, nutrition care is highly variable. Crohn's disease often requires aggressive dietary management because it can lead to protein-energy malnutrition (PEM), nutrient deficiencies, and growth failure in children.

During disease exacerbations, a low-residue, low-fat diet provided in small, frequent feedings can minimize stool output and reduce symptoms of malabsorption. Tube feedings may be necessary to supplement the diet or may be the sole means of providing nutrients; some patients may tolerate elemental formulas more easily than standard formulas. High-kcalorie, high-protein diets are prescribed to prevent or treat malnutrition; the amount of protein recommended may be 50 percent higher than DRI levels.[36] Liquid supplements can increase energy intake and improve weight gain. Vitamin and mineral supplements are usually required, especially if nutrient

colectomy: removal of a portion or all of the colon.

DIET-DRUG INTERACTIONS

Check this table for notable nutrition-related effects of the medications discussed in this chapter.

	Gastrointestinal Effects	Interactions with Dietary Substances	Metabolic Effects
Antidiarrheals	Constipation.	—	—
Anti-inflammatory drugs (sulfasalazine, corticosteroids)	Nausea, heartburn (sulfasalazine).	Sulfasalazine may decrease folate absorption; supplementation is recommended.	Anemia (sulfasalazine); fluid retention, hyperglycemia, hypocalcemia, hypokalemia, hypophosphatemia, increased appetite, protein catabolism (corticosteroids).
Laxatives	Diarrhea.	Mineral oil may decrease absorption of fat-soluble vitamins, but it is not often used.	Fluid and electrolyte imbalances, laxative dependency.
Pancreatic enzyme replacements	Diarrhea, nausea, stomach cramps, irritation to GI mucosa.	—	—

TABLE 24-8 Management of Symptoms and Complications in Crohn's Disease

Symptom or Complication	Possible Dietary Measures
Growth failure/weight loss	High-kcalorie diet Enteral supplements Elemental tube feedings
Anorexia/pain with eating	Small, frequent meals Enteral supplements If long-term (>5 to 7 days): elemental tube feedings
Malabsorption	High-kcalorie diet Nutrient supplementation
Steatorrhea (fat malabsorption)	Fat restriction Medium-chain triglycerides Nutrient supplementation
Diarrhea	Fluid and electrolyte replacement Nutrient supplementation
Lactose intolerance	Avoidance of lactose-containing foods
Nutrient deficiencies	Nutrient-dense diet Nutrient supplementation
Intestinal recovery	High-protein diet Glutamine supplementation
Strictures/fistulas	Low-fiber diet
Severe bowel obstruction/high-output fistulas/severe exacerbations of disease	Total parenteral nutrition

malabsorption is present; nutrients at risk include iron, magnesium, zinc, calcium, vitamin D, vitamin B_{12}, and folate.[37] Table 24-8 includes examples of other dietary adjustments that may be beneficial for patients with Crohn's disease.

During periods of remission, dietary restrictions are unnecessary unless complications develop. Symptoms that may interfere with adequate food intake include anorexia, pain, and diarrhea. Restricted intake of lactose, fructose, and sorbitol may improve symptoms of diarrhea or intestinal gas. Adequate fluid replacement should be encouraged in patients with diarrhea. Individuals with partial obstructions may need to restrict high-fiber foods. Although research studies suggest that supplementation with fish oil, glutamine, or probiotics may be helpful, more research is necessary to confirm these benefits.[38]

Nutrition Therapy for Ulcerative Colitis In most cases, the diet for ulcerative colitis requires few adjustments. As in Crohn's disease, the symptoms and complications that arise are managed with specific dietary measures (see Table 24-8). During disease exacerbations, the primary goals are to restore fluid and electrolyte balances and correct deficiencies that result from protein and blood losses; dietary adjustments are based on the extent of bleeding and diarrhea output. Thus, adequate protein, energy, fluid, and electrolytes need to be provided. A low-fiber diet may reduce irritation by minimizing fecal volume. If colon function becomes severely impaired, food and fluids may be withheld and fluids and electrolytes supplied intravenously until colon function is restored.[39]

Short Bowel Syndrome

The treatment of Crohn's disease, cancers of the small intestine, and other intestinal disorders may include the surgical resection of a major portion of the small intestine. **Short bowel syndrome** is the malabsorption syndrome that results when the absorptive capacity of the remaining intestine is insufficient for meeting nutritional needs. Without appropriate dietary adjustments, short bowel syndrome can result in fluid and electrolyte imbalances and multiple nutrient deficiencies. Symptoms include diarrhea, steatorrhea, dehydration, weight loss, and growth impairment in children.

short bowel syndrome: the malabsorption syndrome that follows resection of the small intestine, which results in insufficient absorptive capacity in the remaining intestine.

Consequences of Short Bowel Syndrome Figure 24-3 reviews nutrient absorption in the GI tract and describes how absorption is affected by surgical resections. Generally, up to 50 percent of the small intestine can be resected without serious nutritional consequences.[40] More extensive resections lead to generalized malabsorption, and patients may need lifelong parenteral nutrition to supplement oral intakes. Other problems that may develop include kidney stones (due to the effects of fat malabsorption on urinary oxalate levels; review p. 761) and gallstones (due to bile malabsorption and the subsequent imbalance between bile acid and cholesterol concentrations in bile; see Chapter 25). Furthermore, loss of the ileocecal valve (between the ileum and cecum) increases the likelihood that colonic bacteria will infiltrate the small intestine and cause bacterial overgrowth.

Intestinal Adaptation After an intestinal resection, the remaining intestine undergoes **intestinal adaptation**, an adaptive response that dramatically improves its absorptive efficiency. Adaptation depends on the presence of nutrients in the lumen, and therefore oral intakes are begun as soon as possible after surgery to stimulate the growth of intestinal tissue. Many patients can eventually return to a normal diet if their intestinal adaptation compensates sufficiently for the removed length of intestine.

The adaptive changes are more prominent in the ileum; thus, removal of the ileum ultimately has more severe consequences than removal of the jejunum. Over a one- to two-year period after resection of the jejunum, the ileum gradually develops taller villi and deeper crypts; it also increases in diameter and length, improving its absorptive capacity enough to replace the jejunum's absorptive functions. Loss of the ileum, however, can permanently disrupt both bile acid and vitamin B_{12} absorption. Depletion of bile acids exacerbates fat malabsorption; furthermore, the unabsorbed bile acids can worsen diarrhea because they irritate the colon walls and increase colonic secretions.[41]

Intestinal adaptation is achieved more easily if both the ileum and colon remain intact. A functional colon is beneficial because its resident bacteria metabolize unabsorbed nutrients and produce some usable nutrients, such as short-chain fatty acids, that are readily absorbed in the colon. An intact colon also helps to reduce losses of fluids and electrolytes.

intestinal adaptation: after resection, the process of intestinal recovery that leads to improved absorptive capacity.

FIGURE 24-3 Nutrient Absorption and Consequences of Intestinal Surgeries

About 90 to 95 percent of nutrient absorption takes place in the first half of the small intestine. After a resection, nutrient absorption may be reduced.

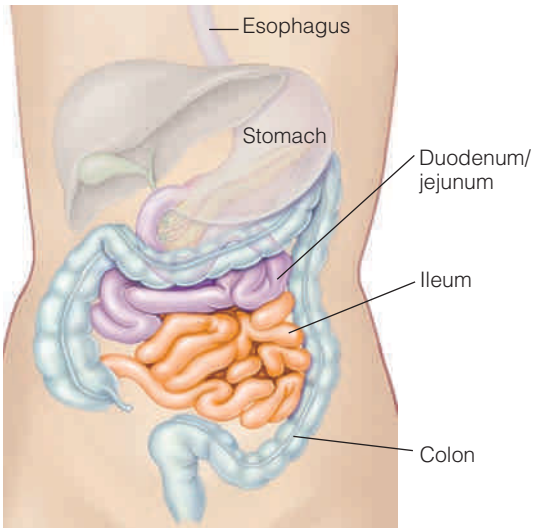
WHAT IS ABSORBED

Duodenum/jejunum
- Simple carbohydrates
- Fats
- Amino acids
- Vitamins[a]
- Minerals[a]
- Water

Ileum
- Bile salts
- Vitamin B_{12}
- Water

(Assumes absorptive function of duodenum and jejunum with adaptation)

Colon
- Water
- Electrolytes
- Short-chain fatty acids



POSSIBLE CONSEQUENCES OF RESECTION

Duodenum/jejunum
- Minimal consequences if the ileum remains intact
- Calcium and iron malabsorption if duodenum resected

Ileum
- Fat malabsorption
- Protein malabsorption
- Malabsorption of fat-soluble vitamins and vitamin B_{12}
- Reduced calcium, magnesium, and zinc absorption
- Fluid losses
- Diarrhea/steatorrhea

Colon
- Fluid and electrolyte losses
- Diarrhea

(Losses are compounded if ileum is also resected)

[a] The absorption of vitamins and minerals begins in the duodenum and continues throughout the length of the small intestine.

Treatment of Short Bowel Syndrome To meet their nutritional needs with enteral nutrition alone, adults need at least 40 to 80 inches (100 to 200 centimeters) of small intestine; the length required depends on the region of intestine that remains. If patients do not have adequate absorptive capacity, the usual treatment is lifelong parenteral nutrition. Intestinal transplantation is an option for patients who cannot continue parenteral nutrition because of life-threatening complications.

Nutrition Therapy for Short Bowel Syndrome Immediately after a resection, fluids and electrolytes must be supplied intravenously. In the first few weeks after surgery, the fluid losses from diarrhea can be substantial (sometimes exceeding 2 liters per day), so appropriate rehydration therapy is critical to recovery. Antidiarrheal medications may be needed to limit losses. The diarrhea gradually lessens as intestinal adaptation progresses.

Total parenteral nutrition meets nutrient needs after surgery and is gradually reduced as oral feedings increase. To promote intestinal adaptation, oral feedings may be started just a few days after surgery, after diarrhea subsides somewhat and some bowel function is restored. Initial oral intake may consist of occasional sips of clear, sugar-free liquids, with intake progressing to larger amounts of liquid formulas and then to solid foods, as tolerated. Very small, frequent feedings can utilize the remaining intestine most efficiently. Parenteral feedings are tapered and gradually discontinued once oral intakes can supply adequate nourishment. Some patients require tube feedings in addition to oral feedings to successfully meet nutrient needs.

The exact diet prescribed for short bowel syndrome depends on the portion of intestine removed, the length of intestine that remains, and whether the colon is still intact; moreover, dietary readjustments may be required as intestinal adaptation progresses.[42] A high-kcalorie intake is typically recommended to compensate for malabsorption. To provide adequate kcalories, a high-fat, low-carbohydrate diet may be recommended if the fat is sufficiently tolerated. Conversely, a high-complex-carbohydrate, low-fat diet may be suggested for patients who have an intact colon. The carbohydrate stimulates the production of short-chain fatty acids in the colon, thereby providing an additional 500 to 1000 kcalories daily, and the low fat intake can improve steatorrhea. In some cases, medium-chain triglycerides may be added as an energy source.

CASE STUDY Economist with Short Bowel Syndrome

Judi Morel is a 28-year-old economist with an 8-year history of Crohn's disease. Judi is 5 feet 7 inches tall. Three years ago, she underwent a small bowel resection and remained free of active disease for 2 years. During that time, her symptoms subsided; she was able to tolerate most foods without any problem and gained weight. Ten months ago, Judi experienced a severe flare-up of her Crohn's disease. Since that time, she has lost 15 pounds and currently weighs 118 pounds. She has experienced severe abdominal pain and fatigue that have persisted despite aggressive medical management that included intravenous nutrition. Five days ago, Judi finally underwent another resection, which left her with 40 percent of healthy small intestine. Her colon is intact. She is experiencing extensive diarrhea.

1. Describe the manifestations of Crohn's disease, and explain why surgery is sometimes performed as part of the treatment. Describe the complications of disease that may affect nutrient needs.
2. Using the BMI table in the back of the book, check the ideal weight range for a person of Judi's height. What nutrition-related concerns are suggested by Judi's recent weight loss? What other nutrition problems did Judi probably experience as a consequence of Crohn's disease?
3. Discuss the complications that may follow an extensive intestinal resection. What factors may affect a person's ability to meet nutrient needs with an oral diet?
4. Discuss the dietary progression that is recommended following an intestinal resection. After Judi is able to eat solid foods, what factors may affect the type of diet that is recommended for her?

Dietary choices are tailored according to individual symptoms and tolerances. Some patients may be lactose intolerant, but they can lessen symptoms by consuming small amounts of lactose-containing foods throughout the day. Patients should avoid concentrated sweets, which draw fluid into the intestines, if they cause additional diarrhea. Due to the high risk of developing kidney stones as a result of calcium malabsorption, a low-oxalate diet may be recommended (see Chapter 28).

Vitamin and mineral supplements can prevent deficiencies from developing due to malabsorption. If fat is malabsorbed, patients may need supplements of fat-soluble vitamins, calcium, magnesium, and zinc. If a large portion of the ileum has been removed, vitamin B_{12} must be injected. Iron absorption is likely to be compromised if upper portions of the small intestine have been removed. Other nutrients at risk may include vitamin A, vitamin C, potassium, and selenium.[43] The Case Study on p. 773 can help you review the material on short bowel syndrome.

IN SUMMARY

Disorders of the small intestine that cause damage to mucosal tissue, such as celiac disease and Crohn's disease, often result in malabsorption. A gluten-free diet can alleviate the symptoms of celiac disease. Intestinal resection is often necessary to treat Crohn's disease. Ulcerative colitis is an inflammatory condition that affects the colon only, and severe cases can be treated by colectomy. Short bowel syndrome is a frequent consequence of major resections of the small intestine and may require permanent parenteral nutrition support. In many patients, intestinal adaptation may improve absorptive capacity after surgical resection.

Conditions Affecting the Large Intestine

The large intestine moves undigested materials to the rectum and has a central role in maintaining fluid and electrolyte balances. Its bacterial population ferments the undigested nutrients that reach the colon and produces short-chain fatty acids and some vitamins that our bodies can absorb and use. This section describes several conditions that may disrupt the normal functioning of the large intestine.

Irritable Bowel Syndrome

◆ Irritable bowel syndrome was introduced in Highlight 3.

People with **irritable bowel syndrome** ◆ experience chronic and recurring intestinal symptoms that cannot be explained by specific physical abnormalities. The symptoms may include both diarrhea and constipation, abdominal pain or discomfort, flatulence, and distention; the abdominal pain is generally aggravated by eating and relieved by defecation. In some patients, symptoms may be mild; in others, the disturbances in defecation can interfere with work and social activities and dramatically alter lifestyle and sense of well-being. Irritable bowel syndrome generally occurs in individuals between 30 and 50 years of age and affects twice as many women as men. About 30 percent of people with the disorder eventually become asymptomatic.[44]

irritable bowel syndrome: an intestinal disorder of unknown cause that affects the functioning of the lower bowel; symptoms include abdominal pain, flatulence, diarrhea, and constipation.

Although the causes of irritable bowel syndrome remain elusive, people with the disorder tend to have excessive colonic responses to meals, GI hormones, and stress. Many individuals exhibit hypersensitivity to a normal degree of intestinal distention and may feel discomfort when experiencing normal meal transit or typical amounts of intestinal gas. Intestinal motility after meals may be excessive, leading to diarrhea, or be reduced, causing constipation. Symptoms often worsen during

periods of psychological stress, and stressful life events may trigger the illness. Some evidence suggests that an infection may cause the initial GI disturbance and that tissue sensitization persists after the infection has healed.

Diagnosing irritable bowel syndrome is often difficult because its symptoms are typical of other GI disorders and laboratory tests for the condition are nonexistent. Up to 5 percent of patients with symptoms of irritable bowel syndrome are found to have celiac disease.[45] Other GI disturbances that may cause similar symptoms include bacterial overgrowth, inflammatory bowel diseases, lactose intolerance, hypothyroidism or hyperthyroidism, and intestinal cancers. Between 40 and 60 percent of patients diagnosed with irritable bowel syndrome have coexisting psychiatric illnesses, such as anxiety, depression, or panic disorder, which can exacerbate symptoms or reduce the ability to cope with the GI condition.[46]

Treatment of Irritable Bowel Syndrome Medical treatment of irritable bowel syndrome often includes dietary adjustments, stress management, and behavioral therapies. Medications may be prescribed to manage symptoms, although they are not always helpful. The drugs prescribed may include antidiarrheal agents, anticholinergics (which affect GI motility), antidepressants, and laxatives.

Nutrition Therapy for Irritable Bowel Syndrome Although dietary adjustments may be useful, measures that help one symptom can sometimes make another worse. The usual dietary advice is to increase fiber intake to 25 to 35 grams per day, which helps to reduce constipation and improve stool bulk.[47] To minimize discomfort from intestinal gas, patients should add fiber-containing foods gradually. They should avoid dietary substances that produce excessive gas unless they can tolerate these foods (review Table 24-2). If diarrhea persists, a bulking agent (psyllium) is usually effective.

A careful evaluation of the diet history can help to reveal the foods and behaviors most closely associated with intestinal discomfort. Avoidance of milk products may benefit those who are lactose intolerant. Patients should avoid caffeine and alcohol because they can exacerbate GI symptoms. Other adjustments that are often helpful include consuming small, frequent meals instead of larger ones and avoiding fatty foods. Psychological associations have a strong influence on food tolerance, so foods that patients perceive to be problematic should be discussed so that

CASE STUDY New College Graduate with Irritable Bowel Syndrome

Marcy Hudson is a 22-year-old recent college graduate who began her first professional job in a bank one month ago. As a college student, she occasionally experienced abdominal pain and cramping after eating. She also had frequent bouts of diarrhea and felt somewhat better after bowel movements. Once Marcy began her new job, her symptoms occurred more frequently. At first she attributed her symptoms to job stress, but when the symptoms continued for several months, she decided to see her physician. After taking a careful history and conducting tests to rule out other bowel disorders, the physician diagnosed irritable bowel syndrome. The physician prescribed bulk-forming agents and advised Marcy to keep a record of her food intake and symptoms for one week. Marcy was then referred to a dietitian for a review of her dietary record. The dietitian noticed that Marcy routinely drank several cups of coffee in the morning and had large meals for lunch and dinner. Marcy often ate out in Mexican restaurants and favored highly spiced foods and refried beans. Between meals, she snacked on low-carbohydrate foods sweetened with sugar alcohols and drank several cans of soda daily. Her dietary fiber intake, however, totaled only about 15 grams daily.

1. Describe the characteristics of irritable bowel syndrome to Marcy, and indicate the role that stress might play in her illness.
2. Explain how the record of food intake and symptoms might be helpful in devising an appropriate diet plan for Marcy. Are any of the foods in Marcy's diet likely to be aggravating her symptoms?
3. What dietary measures might benefit individuals with irritable bowel syndrome? What problems might the dietary changes cause?

the diet is not restricted unnecessarily. Review the Case Study on p. 775 to apply your knowledge about irritable bowel syndrome to a clinical situation.

Diverticular Disease of the Colon

◆ Diverticulosis was introduced in Highlight 3.

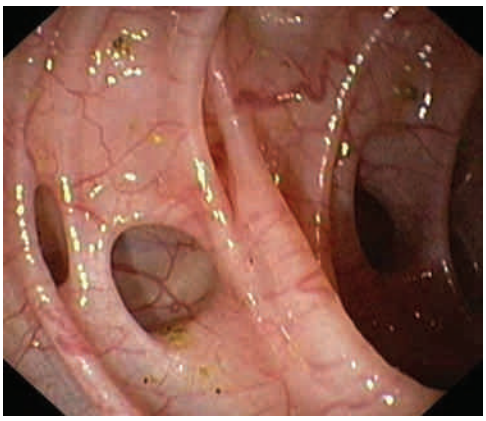
Diverticulosis ◆ refers to the presence of pebble-sized herniations (protrusions) in the intestinal wall, known as diverticula (see the photo). In Western societies, the diverticula occur most often in the sigmoid colon, the portion of the colon just above the rectum. The prevalence of diverticulosis increases with age, occurring in 50 to 80 percent of individuals over 80 years of age.[48] Most people with diverticulosis are symptom-free and remain unaware of the condition until a complication develops.

Epidemiological studies suggest that the development of diverticula is strongly influenced by the amount of dietary fiber a person consumes. Researchers have theorized that the increased stool weight and bulk associated with high-fiber diets may reduce the workload of the circular muscles that move wastes through the colon.[49] Low-fiber diets require more vigorous muscle contractions, increasing pressure within the segments immediately adjacent to the circular muscles. This increase in pressure induces small areas of intestinal tissue to balloon outward over time.

Diverticulitis Inflammation or infection sometimes develops in the area around a diverticulum. This condition, called *diverticulitis,* is the most common complication of diverticulosis, affecting 10 to 25 percent of individuals with the condition.[50] It is thought to result from hardened fecal matter that abrades the mucosal lining, causing inflammation and possibly a microperforation that leads to subsequent infection. If the infection spreads to adjacent organs, fistulas may develop. Less frequently, the infection spreads to the peritoneal cavity, causing life-threatening illness. Symptoms of diverticulitis may include persistent abdominal pain, tenderness in the affected area, fever, constipation, diarrhea, and bleeding. Anorexia, nausea, and vomiting may also occur.

Treatment for Diverticular Disease Treatment for diverticulosis is necessary only if symptoms develop. Because increasing dietary fiber may prevent disease progression and the development of intestinal symptoms, patients are advised to consume a high-fiber diet, with an emphasis on insoluble fiber sources. The fiber intake should be gradually increased to ensure tolerance. Bulk-forming agents, such as psyllium, can raise fiber intakes if food sources are insufficient. Avoiding nuts and seeds is sometimes suggested to prevent disease progression and complications, but evidence is inadequate to justify or refute the recommendation.[51]

Patients with diverticulitis may need antibiotics to treat infections and, possibly, pain-control medications. In mild cases, a clear liquid diet may be advised initially, with progression to solid foods as symptoms resolve. In more severe cases, bowel rest is necessary (oral fluids and food are withheld), and fluids are given intravenously. Oral intakes are gradually reintroduced as the condition improves, beginning with clear liquids and progressing to a restricted-fiber, low-residue diet until inflammation and bleeding subside.[52] After recovery, a high-fiber diet is recommended to prevent disease progression and symptom recurrence. Surgical interventions are sometimes necessary to treat complications of diverticulitis and may include removal of the affected portion of colon.[53]



© Hans Bjorknas/Gastrolab

Diverticulosis is charcterized by herniations in the intestinal wall, which are asymptomatic unless complicated by infection or inflammation.

IN SUMMARY

Irritable bowel syndrome and diverticular disease are common disorders affecting the colon. Irritable bowel syndrome is characterized by abdominal pain and alternating diarrhea and constipation. Although the causes are unknown, the disorder is influenced by stress and psychological factors. Diverticulosis is often asymptomatic until complications develop; its prevalence increases with advancing age and may be related to low fiber intakes. Patients with irritable bowel syndrome or diverticulosis may benefit from a high-fiber diet.

Colostomies and Ileostomies

An *ostomy* is a surgically created opening (called a **stoma**) in the abdominal wall through which dietary wastes can be eliminated. A permanent ostomy is necessary after a partial or total colectomy. A temporary ostomy is sometimes constructed so that part or all of the colon can be bypassed after injury or extensive surgery. To create the stoma, the cut end of the remaining segment of functioning intestine is brought through an opening in the abdominal wall and stitched in place so that it empties to the exterior. The stoma can be formed from a section of the colon **(colostomy)** or ileum **(ileostomy),** as shown in Figure 24-4. Conditions that may require these procedures include inflammatory bowel diseases, diverticulitis, and colorectal cancers.

To collect wastes, a disposable bag is affixed to the skin around the stoma and emptied during the day as needed. Alternatively, an interior pouch can be surgically constructed behind the stoma using intestinal tissue, and the pouch can be emptied with a catheter when convenient. Stool consistency varies according to the length of colon that is functional. If a small portion of the colon is absent or bypassed, the stools may continue to be semisolid. If the entire colon has been removed or is bypassed, absorption of fluid and electrolytes into the body is reduced substantially, and the output is liquid. Due to the difficulty in obtaining enough water to replace losses, patients with ileostomies often have low urine output and an increased risk of developing kidney stones.

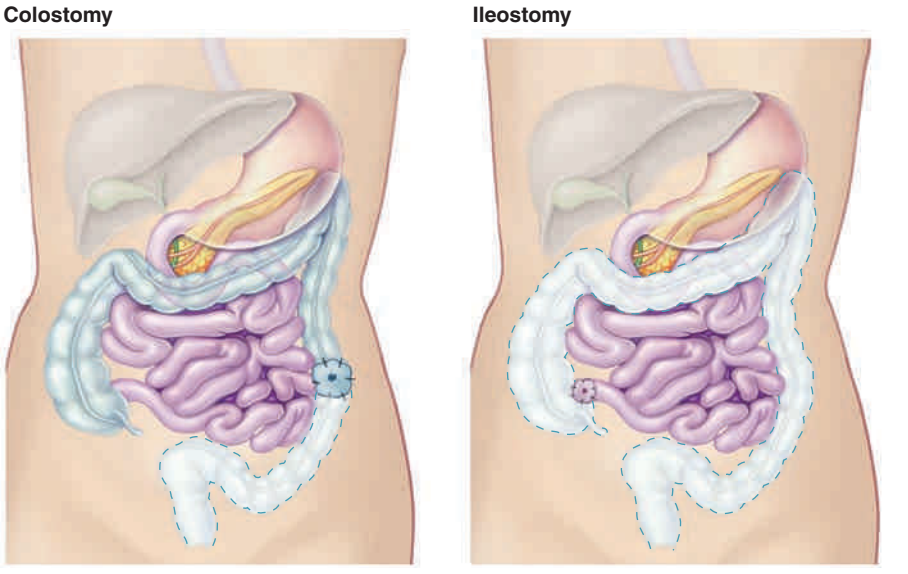
Nutrition Therapy for Patients with Ostomies The nutrition care after an ostomy depends on the length of colon removed and the portion of ileum that remains, so dietary adjustments are individualized according to the surgical procedure and symptoms that develop afterward. Following surgery, the diet gradually progresses from clear liquids that are low in sugars to a normal meal plan, as tolerated. To reduce stool output, a low-residue diet is often recommended. To determine food tolerances, patients should add questionable foods to the diet one at a time and in small amounts to assess their effects; a food that causes problems can be tried again later. Appropriate fluid and electrolyte intakes should be encouraged when a large portion of the colon has been removed.

stoma (STOE-ma): a surgical opening made in the abdominal wall.

colostomy (co-LAH-stoe-me): a surgical procedure that creates a stoma using a section of the colon.

ileostomy (ill-ee-AH-stoe-me): a surgical procedure that creates a stoma using the ileum.

FIGURE 24-4 Colostomy and Ileostomy



In a colostomy, a portion of the colon is removed or bypassed, and the stoma is formed from the remaining section of functional colon.

In an ileostomy, the entire colon is removed or bypassed, and the stoma is formed from the ileum.

People with ileostomies need to chew thoroughly to ensure that foods can be adequately digested and to prevent obstructions, which are a common complication due to the small diameter of the ileal lumen. Foods high in insoluble fibers are sometimes avoided because they shorten intestinal transit time, may cause obstructions, and increase stool output. Because the colon is no longer available for reabsorbing water, the diet should provide at least 8 cups of liquid daily to prevent dehydration. To ensure adequate electrolyte intakes, patients are encouraged to use salt liberally and to ingest beverages with added electrolytes (such as sports drinks and oral rehydration beverages), if necessary. If a large portion of the ileum has been removed, fat malabsorption may occur due to bile acid depletion, and vitamin B_{12} injections may be required.

Dietary concerns after colostomies depend on the length of colon remaining. Most patients have no dietary restrictions and can return to a regular diet.[54] Patient concerns may include stool odors, excessive gas production, and diarrhea. If a large portion of colon was removed, recommendations may be similar to those given to ileostomy patients.

Obstructions As mentioned, foods that are incompletely digested can cause obstructions, a primary concern of ileostomy patients. Although these patients can consume almost any food that is cut into small pieces and carefully chewed, the following foods may cause difficulty: celery, coconut, corn, dried fruit, grapes, nuts, popcorn, raw cabbage (for example, in coleslaw), and unpeeled apples.[55]

Reducing Gas and Odors Persons with ostomies are often concerned about foods that may increase gas production or cause strong odors. Foods that may cause excessive gas include those listed in Table 24-2 on p. 758; practices that increase gas formation include smoking, gum chewing, tobacco chewing, using drinking straws, and eating quickly. Foods that sometimes produce unpleasant odors include asparagus, beer, broccoli, brussels sprouts, cabbage, dried beans and peas, eggs, fish, garlic, and onions. Foods that may help to reduce odors include buttermilk, cranberry juice, parsley, and yogurt.[56]

Diarrhea Examples of foods that may aggravate diarrhea were listed in Table 24-3 on p. 759. Foods and dietary substances that may thicken stool include applesauce, banana flakes, cheese, creamy peanut butter, marshmallows, pasta, pectin, potatoes, pretzels, white bread, and white rice.[57] What works may differ for each individual, however, and is best determined by trial and error.

IN SUMMARY

Colostomies and ileostomies are surgically created openings in the abdominal wall using the colon or ileum. Fluid and electrolyte requirements are greater after an ostomy because colon function is reduced or absent. Foods that are poorly digested may cause obstructions in people with ostomies, although thorough chewing can reduce risk. These individuals should avoid foods if they provoke diarrhea or cause excessive gas or strong odors.

Clinical Portfolio

CENGAGENOW™
academic.cengage.com/login

1. A health practitioner working with a patient with a constipation problem provided him with detailed information about a high-fiber diet. At a follow-up appointment, the patient reported no change in symptoms. His food diary for that day showed that he consumed an omelet and toast for breakfast and a sandwich with juice for lunch.
   - Considering these two meals only, what additional information would help the health practitioner evaluate the man's compliance with the diet he was given?
   - Review the discussion about fiber in Chapter 4, and create a one-day menu that provides the DRI for fiber for an adult male, using the fiber values listed in Appendix H.
2. Using Table 24-5 on p. 762 as a guide, plan a day's menus for a diet containing 50 grams of fat. Take care to make the meals both palatable and nutritious. How can these menus be improved using the suggestions in the "How to" on p. 763?
3. As stated in this chapter, treatment of celiac disease is deceptively simple—eliminate wheat, barley, and rye, and possibly oats. Remaining on a gluten-free diet is more challenging than it appears, however.
   - Randomly select ten of your favorite snack and convenience foods. Take a trip to the grocery store, and check the labels of the products you selected to see if they would be allowed on a gluten-free diet. Keep in mind that the labels may not list all offending ingredients.
   - Find acceptable substitutes for the products that are not allowed, either by substituting other foods or by checking for gluten-free products in the grocery store. If you have access to the Internet, you may want to investigate websites that advertise gluten-free products to get an idea of what's available.

NUTRITION ASSESSMENT CHECKLIST for People with Lower GI Tract Disorders

Medical History

Check the medical record for diseases that:

- Cause chronic GI symptoms, such as irritable bowel syndrome or ulcerative colitis
- Interfere with pancreatic enzyme secretion, such as chronic pancreatitis or cystic fibrosis
- Interfere with nutrient absorption, such as Crohn's disease or celiac disease

Check for surgical procedures involving the lower GI tract, such as:

- Intestinal resections
- Ileostomy
- Colostomy

Check for the following symptoms or complications:

- Anemia
- Bacterial overgrowth
- Bone disease
- Constipation
- Diarrhea, dehydration
- Fistulas
- Lactose intolerance
- Nutrient deficiencies
- Obstructions
- Oxalate kidney stones
- Poor growth, in children
- Steatorrhea

Medications

Check for medications or dietary supplements that may:

- Cause constipation or diarrhea
- Interfere with food intake by causing nausea, vomiting, cramps, dry mouth, or drowsiness
- Alter appetite or nutrient needs

Dietary Intake

Note the following problems, and contact the dietitian if you suspect difficulties such as:

- Poor appetite or food intake
- Food intolerances
- Inadequate fiber intake, in patients with constipation
- Lactose intolerance, in patients with diarrhea
- Inadequate fluid intake

Anthropometric Data

Measure baseline height and weight. Address weight loss early to prevent malnutrition in patients with:

- Severe or persistent diarrhea
- Nutrient malabsorption

Laboratory Tests

Check laboratory tests for signs of dehydration, electrolyte imbalances, nutrient deficiencies, and anemia in patients with:

- Severe or persistent diarrhea
- Nutrient malabsorption
- Intestinal resections

Physical Signs

Look for physical signs of:

- Dehydration
- Protein-energy malnutrition
- Essential fatty acid and fat-soluble vitamin deficiencies
- Folate and vitamin B_{12} deficiencies
- Mineral deficiencies

STUDY QUESTIONS

CENGAGENOW™

To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. What measures can help to prevent and treat constipation? What are the modes of action of the laxatives used to treat constipation? (pp. 755–757)
2. Describe possible causes of diarrhea and the dietary measures that may be included during treatment. (pp. 758–759)
3. Identify conditions that can cause fat malabsorption, and discuss the primary nutrition problems that can result. (pp. 760–761)
4. Explain why bacterial overgrowth develops, and describe its effects on nutrition status. (pp. 761–763)
5. Explain how chronic pancreatitis and cystic fibrosis can result in malabsorption. In what ways are their dietary treatments similar? (pp. 763–766)
6. Discuss the cause of celiac disease, and describe the diet used in its treatment. Explain why a gluten-free diet may be difficult for patients to follow. (pp. 767–768)
7. Compare the effects of Crohn's disease and ulcerative colitis on nutrition status, and describe the dietary measures that may be required during the course of illness. (pp. 768–771)
8. Identify possible causes of short bowel syndrome. What nutrition problems often develop? Discuss the adaptive process that occurs in the remaining intestine after a portion of intestine is resected. (pp. 771–774)
9. Describe irritable bowel syndrome, and discuss the ways in which diet can be used in its treatment. (pp. 774–776)
10. Specify the factors that increase the risk of developing diverticular disease. What dietary modification is most useful in its prevention and treatment? (p. 776)
11. Describe the primary nutrition-related concerns of people who have undergone ileostomies and colostomies. (pp. 777–778)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 782.

1. The health practitioner advising an elderly patient with constipation encourages the patient to:
   a. consume a low-fat diet low in sodium.
   b. consume a high-protein diet rich in calcium.
   c. eliminate gas-forming foods from the diet.
   d. gradually add high-fiber foods to the diet.
2. Osmotic diarrhea often results from:
   a. excessive colonic contractions.
   b. excessive fluid secretion by the intestines.
   c. nutrient malabsorption.
   d. viral, bacterial, or protozoal infections.

3. Nutrition problems that may result from fat malabsorption include all of the following *except:*
   a. weight loss.
   b. essential amino acid deficiencies.
   c. bone loss.
   d. oxalate kidney stones.
4. Common nutrition problems associated with bacterial overgrowth in the stomach and small intestine include:
   a. sensitivity to gluten.
   b. fat malabsorption and vitamin B_{12} deficiency.
   c. constipation.
   d. permanent loss of digestive enzymes.
5. The majority of chronic pancreatitis cases can be attributed to:
   a. bacterial and viral infections.
   b. gallstones.
   c. excessive alcohol use.
   d. elevated triglyceride levels.
6. Chronic pancreatitis and cystic fibrosis are both treated with:
   a. intestinal resection.
   b. postural drainage.
   c. enzyme replacement therapy.
   d. stool softeners.
7. A person on a gluten-free diet must avoid products containing:
   a. wheat, barley, and rye.
   b. barley, soybeans, and corn.
   c. wheat, corn, and rice.
   d. buckwheat, rice, and millet.
8. Symptoms of irritable bowel syndrome most often include:
   a. nausea and vomiting.
   b. weight loss and malnutrition.
   c. strong odors and obstructions.
   d. constipation, diarrhea, and flatulence.
9. Diverticulosis is most often usually associated with:
   a. a low-fiber diet.
   b. inadequate exercise.
   c. intestinal surgery.
   d. a high-fiber diet.
10. After an ileostomy, the most serious concern is that:
    a. the diet is too restrictive to meet nutrient needs.
    b. waste disposal causes frequent daily interruptions.
    c. fluid restrictions prevent patients from drinking beverages freely.
    d. incompletely digested foods may cause obstructions.

Probiotics and Intestinal Health

Soon after birth, the warm, nutrient-rich environment within the gastrointestinal tract is colonized by a wide variety of bacterial species. The approximately 10 trillion cells of bacteria inhabiting our bodies **(flora)** make up more than 90 percent of all our cells. Most bacterial cells reside in our colon, which harbors over 400 different species.[1] Although the exact composition of intestinal bacteria varies among individuals, the pattern within an individual tends to remain constant over time, fluctuating somewhat due to illness, antibiotic treatment, and to some extent, dietary factors. Table H24-1 lists the predominant types of bacteria that colonize the human intestines, and Table H24-2 shows how the bacterial populations vary within different regions of the GI tract.

Over the past several decades, nutritional scientists and microbiologists have tried to determine whether **probiotics**—live, **nonpathogenic** bacteria supplied in sufficient numbers to possibly benefit our health—can be useful for preventing or treating various medical conditions. Although the diseases of interest include gastrointestinal disorders, researchers have also been studying the effects of bacterial cells on cancer, immune system disorders, and other illnesses. This highlight discusses some of the research and explains some of the issues involved in selecting and consuming probiotic bacteria. The accompanying glossary defines the relevant terms.

TABLE H24-1 Intestinal Flora

Predominant Types	Subdominant Types
Bacteroides	Enterobacteria
Bifidobacteria	Enterococci
Clostridia	*Escherichia* species
Eubacteria	*Klebsiella* species
Peptococcus species	Lactobacilli
Peptostreptococcus species	Micrococci
Ruminococcus species	Staphylococci

TABLE H24-2 Bacterial Populations in the Gastrointestinal Tract

Organ	Total Bacteria (per mL of contents)
Stomach	0 to 100
Small intestine: duodenum	0 to 1000
Small intestine: jejunum and ileum	10^5 to 10^8
Colon	10^{10} to 10^{12}

Our Intestinal Flora

Intestinal bacteria can benefit our health in a number of different ways. First, the bacteria degrade much of our undigested or unabsorbed dietary carbohydrate, including dietary fibers, starch that is resistant to digestion, and poorly absorbed sugars and sugar alcohols. In turn, the bacteria produce some vitamins, as well as short-chain fatty acids that our cells can use as an energy source. Intestinal bacteria also stimulate our immune defenses and may prevent the overgrowth of **pathogenic** bacteria in the gastrointestinal tract. Healthy bacteria may help to prevent invasion of our tissues by pathogenic bacteria by creating a barrier on the intestinal walls.[2]

Probiotic Bacteria

For bacteria to be "probiotic"—that is, beneficial to health—they must be nonpathogenic when consumed. They must survive their transit through the digestive tract; therefore, they must be resistant to destruction by stomach acid, bile, and other digestive substances. They should be able to alter the intestinal environment in some way that is beneficial to the human host, either by producing antimicrobial substances, altering immune defenses, metabolizing undigested foodstuffs, or protecting the intestinal walls.[3]

Probiotic bacteria must be consumed in high amounts—between 100 million and 100 billion live bacteria per day—to

GLOSSARY

flora: the bacteria that normally reside in a person's body.

nonpathogenic: not capable of causing disease.

pathogenic: capable of causing disease.

prebiotics: nondigestible substances in foods that stimulate the growth of probiotic bacteria within the large intestine.

probiotics: live bacteria provided in foods and dietary supplements for the purpose of preventing or treating disease.

survive in sufficient numbers to influence the bacterial populations in the large intestine; a serving of yogurt usually provides these amounts. Carefully controlled studies have not found that probiotic bacteria actually *colonize* the intestine, however, as they are no longer detected in fecal or intestinal samples once ingestion of the probiotic product stops.[4] Note that only a few different types of bacteria are used in foods, and the relatively small amounts consumed cannot compete with the huge populations that normally populate our digestive tract.

Probiotic Bacteria and Disease

Although results of research studies vary, probiotic bacteria may help to prevent and treat some gastric and intestinal disorders, alter susceptibility to food allergens and alleviate some allergy symptoms, and improve the availability and digestibility of various nutrients.[5] Some evidence suggests that probiotics may help to prevent or reverse infections in the urethra and vagina.[6] Other potential benefits include improved immune responses, reduced symptoms of lactose intolerance, and reduced cancer risk.[7]

Much of the research investigating probiotics and intestinal illness has focused on the prevention and treatment of infectious diarrhea. For example, controlled trials have suggested that certain strains of probiotic bacteria may shorten the duration of diarrhea caused by rotavirus infection in infants and children, decrease the incidence of traveler's diarrhea in tourists visiting high-risk areas, and prevent the recurrence of infectious diarrhea in hospitalized patients.[8] In studies of children and adults using antibiotics, some strains of probiotic bacteria have been shown to reduce the incidence and duration of antibiotic-associated diarrhea. As another example, some studies have suggested that probiotic treatment may help to reduce the recurrence of *pouchitis,* an inflammation of the surgical pouch created in patients who have had an ileostomy or colostomy.[9]

Despite promising research results thus far, there are no clear conclusions about the appropriate probiotic doses or durations of treatment for many of these conditions.[10] Moreover, the beneficial effects of one bacterial strain cannot be extrapolated to other strains of the same species.[11] Thus, individuals who decide to consume probiotic-containing foods and supplements to benefit their health cannot be certain that the substances they use will help their condition. At best, probiotics should be considered an adjunct therapy rather than a primary treatment for an illness.

Probiotics in the Diet

Probiotics are provided mainly by fermented foods. In the United States, yogurt and acidophilus milk are produced using various species of lactobacilli and bifidobacteria, although the species are chosen for their ability to produce desirable food products rather than their potential health benefits.[12] In Europe and Asia, food products containing probiotic bacteria include yogurt, milk, ice cream, oatmeal gruel, and soft drinks.[13] Although lactobacilli are used to produce various other fermented food products, such as sauerkraut, pickles, brined olives, Korean kimchi, and sausages, the foods do not necessarily contain adequate numbers of live bacteria to benefit health.[14]

© Polara Studios, Inc.

Various species of *Lactobacillus* are used in the production of fermented food products, such as the foods shown in this photo.

A number of companies market probiotic supplements, which are available in capsules, tablets, and powders. Because probiotic bacteria are living organisms, storage conditions may affect their viability—heat, moisture, and oxygen can reduce survival times—and therefore consumers should check the expiration date before purchasing a product. When a consumer group (ConsumerLab .com) tested 13 probiotic supplements, they found that 5 of the products contained substantially fewer live bacteria than was claimed on the label.[15] Thus, there is no guarantee that a dietary supplement will contain the amount of bacteria expected.

Certain nondigestible substances in food, called **prebiotics,** may stimulate the growth or activity of resident bacteria within the large intestine; prebiotics include some of the carbohydrates found in asparagus, chicory root, garlic, Jerusalem artichokes, onions, and other foods.[16] Because the intestinal bacteria that degrade these substances produce gas as a by-product, people who consume high amounts of these foods may experience more flatulence than usual.

Safety Concerns

One major concern is the possibility that probiotic bacteria may cause infection in immune-compromised individuals. Various species of probiotic bacteria, including *Lactobacillus* species, have been isolated from the infection sites of severely ill individuals who were consuming the probiotic orally.[17] The individuals most likely to be susceptible to infectious complications include patients with reduced immunity, such as people with AIDS or cancer and those undergoing organ transplantation. Care should be taken to inquire about probiotic use in these patients.

Other concerns are related to the lack of industry standards for probiotics in foods and supplements: the concentrations of probiotic bacteria in foods may vary substantially. Thus, a consumer who wishes to try probiotics would find it difficult to determine how much of a product to consume in order to achieve the desired effect.

In recent years, the contributions of our intestinal flora to health have been increasingly recognized. Preliminary research suggests

that altering our bacterial populations by consuming probiotics or prebiotics may help to improve our defenses against certain illnesses. Additional studies are needed to verify the beneficial effects of probiotics and prebiotics and to develop standard protocols that can be used for treating illness.

Nutrition in the Clinical Setting

Liver disease progresses slowly. Its primary symptom, fatigue, often goes unnoticed. Other symptoms may be so mild that complications develop before liver disease is diagnosed. Health care providers should emphasize the need to preserve remaining liver function, as healthy liver tissue can proliferate, improving prognosis. Preventing additional damage is the principal means of avoiding liver failure or transplantation.

CHAPTER 25

Liver Disease and Gallstones

CHAPTER OUTLINE

Fatty Liver and Hepatitis • Fatty Liver • Hepatitis

Cirrhosis • Consequences of Cirrhosis • Treatment of Cirrhosis • Medical Nutrition Therapy for Cirrhosis •

Liver Transplantation

Gallbladder Disease • Types of Gallstones • Consequences of Gallstones • Risk Factors for Gallstones • Treatment for Gallstones

HIGHLIGHT 25 Food Allergies

The liver is the most metabolically active organ in the body. As you may recall from Chapter 7, the liver plays a central role in processing, storing, and redistributing the nutrients provided by the meals we eat. ◆ The liver synthesizes most of the proteins that circulate in plasma, including albumin, clotting proteins, and transport proteins. As Chapter 3 described, the liver produces the bile that emulsifies fat during digestion. In addition, the liver detoxifies drugs and alcohol and processes excess nitrogen so that it can be safely excreted as urea. If the liver's numerous roles are upset by liver damage or disease, the effects on health and nutrition status can be profound.

◆ Table 7-1 on p. 215 summarizes the chemical reactions of the liver that are related to the metabolism of carbohydrates, lipids, and protein.

As Figure 25-1 on p. 788 shows, the liver is ideally situated for receiving and processing the nutrients absorbed by the small intestine. The portal vein's nutrient-rich blood supplies 70 to 80 percent of the blood that enters liver tissue, whereas the rest arrives via hepatic arteries. Blood is returned to the heart by way of the hepatic vein and then circulates throughout the body. The **biliary system** of channels and ducts carries bile and other substances from the liver to the duodenum while a meal is being digested. Between meals, the bile is diverted to the gallbladder, where it is stored and concentrated until needed for a subsequent meal.

biliary system: the gallbladder and ducts that deliver bile from the liver and gallbladder to the small intestine.

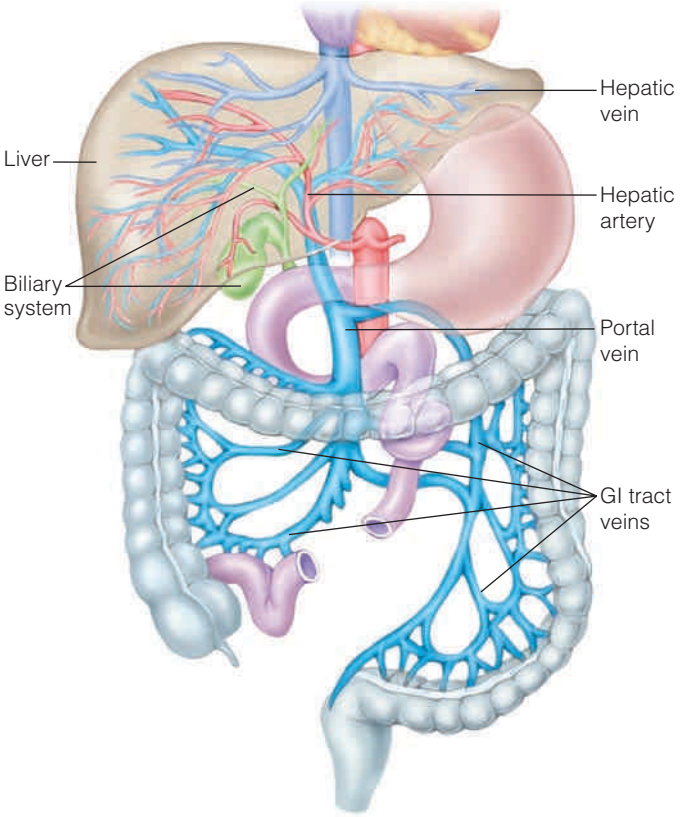
Fatty Liver and Hepatitis

Fatty liver and hepatitis are the two most common disorders affecting the liver. Although both conditions may be mild and are usually reversible, each may progress to more serious illness and eventually cause liver damage.

FIGURE 25-1 The Liver, Biliary System, and Associated Blood Vessels

Liver
Receives nutrients from the digestive tract and processes them for distribution throughout the body.

Biliary system
Includes the gallbladder, which stores and secretes bile, and the bile ducts, which conduct bile from the liver to the gallbladder and from the gallbladder to the intestine.



Hepatic vein
Returns blood from the liver to the heart.

Hepatic artery
Supplies oxygen-rich blood from the heart to the liver.

Portal vein
Carries nutrient-rich blood from the digestive tract to the liver.

GI tract veins
Transport absorbed nutrients to the portal vein.

Fatty Liver

◆ Reminder: *Fatty liver* is an accumulation of triglycerides in the liver; also called *hepatic steatosis* (STEE-ah-TOE-sis).

Fatty liver ◆ is an accumulation of fat in liver tissue. Ordinarily, the liver's triglycerides are packaged into very-low-density lipoproteins (VLDL) and exported to the bloodstream (see Chapter 5). Although the exact reasons why fat accumulates are often unknown, fatty liver represents an imbalance between the amount of fat synthesized in the liver or picked up from the blood and the amount exported to the blood via VLDL. Fatty liver has been estimated to affect 20 percent or more of the adult population in the United States.[1]

◆ Insulin resistance promotes fat accumulation in the liver by stimulating fatty acid synthesis, inhibiting fatty acid oxidation, and blocking VLDL secretion into the bloodstream.

Fatty liver is a clinical finding that is common to many conditions. It is present in the majority of patients who have alcoholic liver disease and can also result from exposure to drugs and toxic metals. As a frequent complication of insulin resistance, fatty liver often accompanies diabetes mellitus, metabolic syndrome, and obesity.[2] ◆ Other causes of fatty liver include long-term total parenteral nutrition, gastrointestinal bypass surgery, and diseases of malnutrition (such as kwashiorkor).[3]

◆ The liver enzymes ALT (alanine aminotransferase) and AST (aspartate aminotransferase) are involved in amino acid catabolism.

hepatomegaly (HEP-ah-toe-MEG-ah-lee): enlargement of the liver.

steatohepatitis (STEE-ah-to-HEP-ah-TIE-tis): liver inflammation that is associated with fatty liver.

Consequences of Fatty Liver In many individuals, fatty liver is asymptomatic and causes no harm. In other cases, it may be accompanied by liver enlargement **(hepatomegaly),** inflammation **(steatohepatitis),** and fatigue. If liver damage and scarring develop, fatty liver may progress to cirrhosis (discussed in a later section), liver failure, or liver cancer.[4]

Fatty liver is a common cause of abnormal liver enzyme levels in the blood. Laboratory findings may include elevated blood concentrations of the liver enzymes ALT and AST, as well as increased levels of triglycerides, cholesterol, and glucose. ◆ Table 17-10 on p. 603 provides normal ranges for these liver enzymes.

Treatment of Fatty Liver The usual treatment for fatty liver is to eliminate the factors that cause it. For example, if fatty liver is due to alcohol abuse or drug treatment, it may improve after the patient discontinues use of the substance. In patients with elevated blood lipids, fatty liver may improve after blood lipid levels are lowered. An appropriate treatment for obese or diabetic patients might be weight reduction, increased physical activity, or medications that improve insulin sensitivity. Rapid weight loss should be discouraged, however, because it may accelerate the progression of liver disease.[5] Note that lifestyle modifications are not always successful in reversing fatty liver, especially in patients who lack the usual risk factors.

Hepatitis

Hepatitis, or liver inflammation, results from damage to liver tissue. Most often, the damage is caused by infection with specific viruses, which are designated by the letters A, B, C, D, and E. Hepatitis can also be caused by excessive alcohol intake, exposure to certain drugs and toxic chemicals, and fatty liver disease. A number of herbal remedies are reported to cause hepatitis; they include chaparral, germander, ma huang, jin bu huan, kava kava, and skullcap.[6] Less common causes of hepatitis include infection with other viruses and autoimmune diseases.

Viral Hepatitis In the United States, acute hepatitis ◆ is most often caused by infection with hepatitis viruses A, B, and C (see Table 25-1).[7] Hepatitis A virus (HAV), which is spread via the fecal-oral route, is due to the contamination of foods and beverages with fecal material. Outbreaks of HAV infection are often associated with floods and other natural disasters, when inadequately treated sewage may contaminate water supplies with fecal matter. Less frequently, HAV infection is spread by consuming undercooked shellfish obtained from contaminated waters. Individuals at highest risk of HAV infection include those in lower socioeconomic groups, day care workers, illicit drug users, and travelers to regions where it is endemic.[8] In the United States, the incidence of HAV infection has declined 88 percent since 1995 as a result of routine vaccinations in children and high-risk individuals.[9] HAV infection usually resolves within a few months and does not cause chronic illness or permanent liver damage.

◆ Hepatitis is considered *acute* if it lasts less than six months; *chronic* cases are those that last six months or longer.

Over half of viral hepatitis cases are caused by infection with hepatitis B or C viruses. Hepatitis B virus (HBV) is transmitted by infected blood or needles or by sexual contact and is carried by at least 1.25 to 1.5 million persons in the United States.[10] As a precautionary measure, HBV vaccinations are recommended for health care workers, sexually active adults, users of illicit injected drugs, and newborn infants and children. Hepatitis C virus (HCV) is transmitted by blood contact as well but is less efficiently spread by sexual contact. HCV is a major cause of chronic hepatitis and is currently carried by 3.2 million individuals in the United States.[11] ◆ No vaccine is available to protect against HCV infection. Chronic HBV or HCV infection may lead to cirrhosis and liver cancer.

◆ There are fewer new cases of HCV infection than of HBV infection each year, but more HCV cases become chronic. Therefore, there are more HCV carriers than HBV carriers.

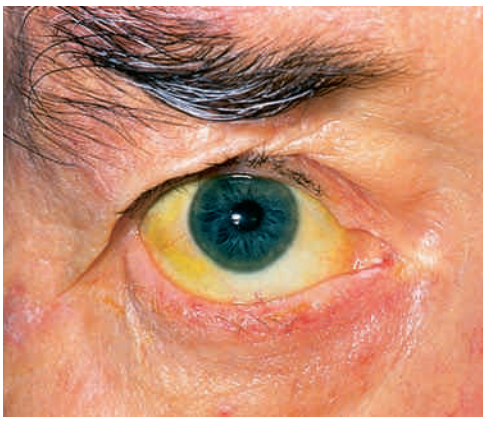
hepatitis (hep-ah-TYE-tis): inflammation of the liver.

TABLE 25-1 Features of Hepatitis Viruses

Hepatitis Virus	% of Viral Cases[a]	Major Mode of Transmission	Chronic Disease Rate (% of cases)	Vaccination Available
A	37	Fecal-oral	None	Yes
B	45	Bloodborne, sexual transmission	2–7	Yes
C	18	Bloodborne	50–85	No

[a]Although not listed here, a small fraction of viral hepatitis cases are caused by hepatitis viruses D and E.

Ausiello, eds., *Cecil Medicine* (Philadelphia: Saunders, 2008), pp. 1101–1108; Centers for Disease Control and Prevention, Surveillance for acute viral hepatitis—United States, 2005, *Morbidity and Mortality Weekly Report* 56, No. SS-3 (2007).



© Dr. P. Marazzi/Science Photo Library/Photo Researchers, Inc.

Jaundice is a yellow discoloration of the tissues that is most easily seen in the whites of the eyes.

◆ Jaundice results when liver dysfunction impairs the metabolism of bilirubin, a breakdown product of hemoglobin that is normally eliminated in bile. Accumulation of bilirubin in the bloodstream leads to yellow discoloration of tissues.

Symptoms of Hepatitis The effects of hepatitis depend on the cause and severity of the disease. Individuals with mild or chronic hepatitis are often asymptomatic. The onset of acute hepatitis may be accompanied by fatigue, nausea, anorexia, and pain in the liver area. The liver is often slightly enlarged and tender. **Jaundice** (yellow discoloration of tissues) may develop, causing yellowing of the skin, urine, and the whites of the eyes. ◆ Other symptoms of hepatitis include fever, headache, muscle weakness, and skin rashes. Increased serum levels of the liver enzymes ALT and AST are common. Chronic hepatitis may cause complications that are typical of liver cirrhosis.

Treatment of Hepatitis Hepatitis is treated with supportive care, such as bed rest (if necessary) and an appropriate diet. Hepatitis patients should avoid substances that irritate the liver, such as alcohol and drugs or dietary supplements that cause liver damage. Hepatitis A infection usually resolves without the use of medications. Antiviral agents may be used to treat HBV and HCV infections; these medications include lamivudine and ribavirin, which block viral replication, and interferon, which both inhibits viral replication and enhances immune responses.[12] Nonviral forms of hepatitis may be treated with anti-inflammatory and immunosuppressant drugs. Hospitalization is not required for hepatitis unless other medical conditions or complications hamper recovery.

Nutrition Therapy for Hepatitis Nutrition care varies according to a patient's symptoms and nutrition status.[13] Some individuals require no dietary changes. Those with anorexia or gastrointestinal discomfort may find small, frequent meals easier to tolerate. Persons who are malnourished should consume adequate protein and energy to replenish nutrient stores; the diet should include 1.0 to 1.2 grams of protein per kilogram of body weight. Individuals with fluid retention should avoid high-sodium foods. A low-fat diet, with fat limited to less than 30 percent of total kcalories, may be necessary for those with steatorrhea. Patients with persistent vomiting may require fluid and electrolyte replacement. Liquid supplements can be helpful for improving nutrient intakes.

TABLE 25-2 Causes of Cirrhosis

Alcoholic liver disease

Autoimmune hepatitis

Bile duct obstructions
- Complications of gallbladder surgery
- Cystic fibrosis
- Diseases that cause bile duct injury

Drug-induced liver injury

Inherited disorders
- Galactosemia
- Glycogen storage disease
- Hemochromatosis (causes excessive liver iron)
- Wilson's disease (causes excessive liver copper)

Steatohepatitis (fatty liver disease)

Viral hepatitis
- Hepatitis B
- Hepatitis C

IN SUMMARY

Fatty liver can result from excessive alcohol intake, drug toxicity, and chronic disorders such as diabetes and obesity. Hepatitis is frequently caused by viral infection but can also result from alcohol abuse, drug toxicity, and other causes. Although fatty liver is often benign, hepatitis can become chronic and lead to cirrhosis and liver cancer. Treatment of hepatitis includes avoiding substances that cause liver damage, taking medications for viral infection, and following dietary measures that improve nutrition status.

jaundice (JAWN-dis): yellow discoloration of the skin and eyes due to an accumulation of bilirubin, a breakdown product of hemoglobin that normally exits the body via bile secretions.

cirrhosis (sih-ROE-sis): an advanced stage of liver disease in which extensive scarring replaces healthy liver tissue, causing impaired liver function and liver failure.

Cirrhosis

Cirrhosis is the final phase of chronic liver disease. Long-term liver disease gradually destroys liver tissue, leading to scarring (fibrosis) in some regions and small areas of regenerated, healthy tissue in others. As the disease progresses, the scarring becomes more extensive, leaving fewer areas of healthy tissue. A cirrhotic liver is often shrunken and has an irregular, nodular appearance. Cirrhosis impairs liver function and can eventually lead to liver failure. It is the 12th leading cause of death in the United States.[14]

Table 25-2 lists some common causes of cirrhosis. In the United States, most cases are caused by alcoholic liver disease and chronic hepatitis C infection, followed by fatty liver disease and chronic hepatitis B infection.[15] Additional causes include other types of chronic hepatitis; bile duct blockages, which cause bile acids to accu-

mulate to toxic levels in the liver; drug-induced liver injury; and inherited disorders that cause toxic substances to build up in the liver.

Consequences of Cirrhosis

About 40 percent of cirrhosis patients are asymptomatic.[16] The effects of cirrhosis may be minimal at first, as liver damage often progresses slowly. Initial symptoms are usually nonspecific and may include fatigue, weakness, anorexia, and weight loss. Later, the decline in liver function can lead to metabolic disturbances: patients may develop anemia, bruise easily, and be more susceptible to infections. If bile obstruction occurs, jaundice and fat malabsorption are likely. The physical changes in liver tissue may interfere with blood flow, causing fluid to accumulate in blood vessels and body tissues. Advanced cirrhosis can disrupt kidney and lung function. Figure 25-2 illustrates some of the clinical effects of liver cirrhosis, and later sections describe some of these complications in more detail.

Table 25-3 on p. 792 lists laboratory tests that are used to monitor the extent of liver damage. Liver enzyme levels are increased because injured liver tissue releases the enzymes into the bloodstream. Levels of bilirubin may be elevated if the liver is too damaged to process it or if bile ducts are blocked and prevent its excretion. Reduced synthesis of plasma proteins by the liver lowers albumin levels and extends blood-clotting time. Liver damage also impairs the conversion of ammonia to urea, causing ammonia levels in the blood to rise.

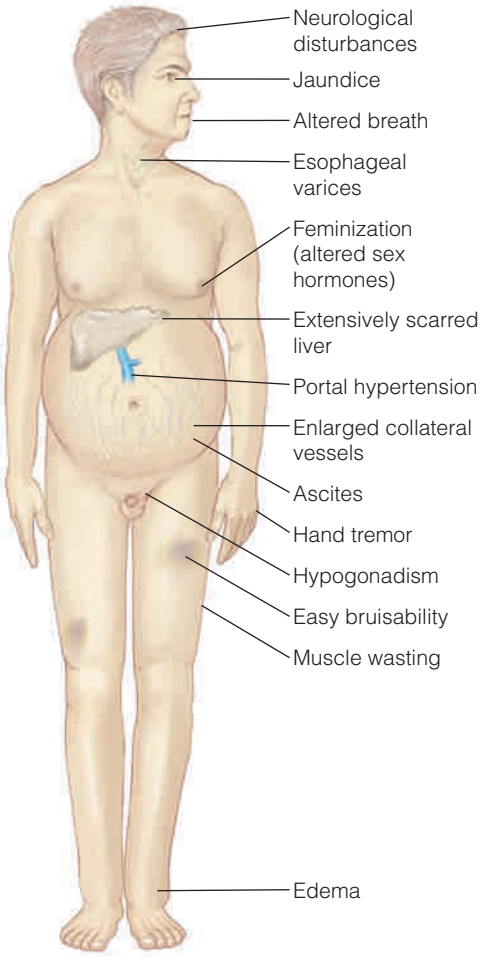
A cirrhotic liver has an irregular, nodular appearance. The nodules represent clusters of regenerating cells within the damaged liver tissue.

FIGURE 25-2 Clinical Effects of Liver Cirrhosis



© Hans Bjorknas/Gastrolab.net

Esophageal varices, such as the one shown here, may protrude into the lumen and be vulnerable to rupture and bleeding.

◆ Reminder: The *portal vein* is the large blood vessel that carries nutrient-rich blood from the digestive tract to the liver.

portal hypertension: elevated blood pressure in the portal vein due to obstructed blood flow through the liver.

collaterals: blood vessels that enlarge to allow an alternative pathway for diverted blood.

varices (VAH-rih-seez): abnormally dilated blood vessels (singular: *varix*).

ascites (ah-SIGH-teez): an abnormal accumulation of fluid in the abdominal cavity.

sinusoids: the small, capillary-like passages that carry blood through liver tissue.

hepatic encephalopathy (en-sef-ah-LOP-ah-thie): a condition in advanced liver disease characterized by altered neurological functioning, including personality changes, reduced mental abilities, and disturbances in motor function.
- **encephalo** = brain
- **pathy** = disease

hepatic coma: loss of consciousness resulting from severe liver disease.

TABLE 25-3 Laboratory Tests for Evaluation of Liver Disease

Laboratory Test	Normal Ranges (serum)	Values in Liver Disease
Alanine aminotransferase (ALT)	Male: 10–40 U/L Female: 7–35 U/L	Elevated
Albumin	3.4–4.8 g/dL	Decreased
Alkaline phosphatase	25–100 U/L	Normal or elevated
Ammonia	15–45 µg N/dL	Elevated
Aspartate aminotransferase (AST)	10–30 U/L	Elevated
Bilirubin (total)	0.3–1.2 mg/dL	Elevated
Blood urea nitrogen (BUN)	6–20 mg/dL	Normal or decreased
Prothrombin time[a]	10–13 seconds	Prolonged

[a]The test for prothrombin time evaluates the clotting ability of blood.
NOTE: U/L = units per liter; N = nitrogen; dL = deciliter.

Portal Hypertension A large volume of blood normally flows through the liver. The portal vein ◆ and hepatic artery together supply approximately 1500 milliliters (about 1.5 quarts) of blood each minute to the extensive network of vessels in the liver. The scarred tissue of a cirrhotic liver impedes the flow of blood, which is mostly supplied by the portal vein. The resistance to blood flow within the liver causes a rise in blood pressure within the portal vein, called **portal hypertension.**

Collaterals and Gastroesophageal Varices When blood flow through the portal vein is impeded, the blood is diverted to the smaller blood vessels surrounding the liver. These **collaterals** develop throughout the gastrointestinal (GI) tract and in regions near the abdominal wall. As pressure builds, the collateral vessels become enlarged and engorged, forming abnormally dilated vessels called **varices** (see the photo). Esophageal and gastric varices are vulnerable to rupture because they have thin walls and often bulge into the lumen. If ruptured, they can cause massive bleeding that is sometimes fatal. The blood loss is exacerbated by the liver's reduced production of blood-clotting factors.

Ascites Within 10 years of disease onset, about 50 percent of cirrhosis patients develop **ascites,** a large accumulation of fluid in the abdominal cavity. The development of ascites indicates that liver damage has reached a critical stage, as half of patients with ascites die within 2 years.[17] Ascites is thought to be a consequence of portal hypertension, reduced albumin synthesis by the diseased liver, and altered kidney function. Portal hypertension raises pressure in the liver's **sinusoids,** forcing fluid to leak from the blood into the abdominal cavity. The fluid accumulation is exacerbated by low plasma albumin levels, because albumin helps to retain the fluid in blood vessels. The increased pressure in the portal vein triggers the release of chemical factors (such as nitric oxide) that dilate blood vessels, thereby lowering the pressure within vessels elsewhere; this activates sodium and water retention by the kidneys and leads to additional water pooling. Ascites can cause abdominal discomfort and early satiety, which contribute to malnutrition. Because ascites can raise body weight considerably, weight changes may be difficult to interpret.

Hepatic Encephalopathy Advanced liver disease sometimes leads to **hepatic encephalopathy,** a disorder characterized by abnormal neurological functioning. Symptoms of hepatic encephalopathy include changes in mental abilities, personality, and motor functions (see Table 25-4). At worst, amnesia, seizures, and **hepatic coma** may develop. Although hepatic encephalopathy is fully reversible with medical treatment, prognosis is poor when it progresses to the advanced stages.[18]

The exact causes of hepatic encephalopathy remain elusive, although elevated blood ammonia levels are thought to play a key role in its development due to ammonia's neurotoxicity.[19] Other compounds potentially toxic to brain tissue, such as

TABLE 25-4 Symptoms of Hepatic Encephalopathy

Early Stages	Middle Stages	Later Stages
Lack of attention	Poor memory	Disorientation
Irritability, depression	Drowsiness	Amnesia
Impaired judgment	Slurred speech	Muscular rigidity
Lack of coordination	Jerking movements	Abnormal reflexes
Tremor	Sleep disorders	Delirium, stupor

sulfur compounds, short-chain fatty acids, and gamma-aminobutyric acid (GABA; a neurotransmitter), may accumulate in brain cells and disturb brain function. Another theory is that the brain's neurotransmitters are altered by an increased ratio of aromatic amino acids to branched-chain amino acids in brain tissue, a result of disordered amino acid metabolism in the liver. ◆ Most likely, a combination of metabolic abnormalities contributes to the disruption in neurological functioning.

Elevated Blood Ammonia Levels Much of the body's free ammonia is produced by bacterial action on unabsorbed dietary protein in the colon. Normally, the liver extracts this ammonia from portal blood and converts it to urea, which is then excreted by the kidneys. In advanced liver disease, ammonia-laden portal blood bypasses the liver by way of collateral vessels and reaches the general blood circulation, causing a substantial increase in the ammonia that reaches brain tissue. Although ammonia levels do not correlate well with the degree of neurological impairment in hepatic encephalopathy, ammonia-reducing medications can successfully reverse the neurological symptoms.[20]

Malnutrition and Wasting Most patients with cirrhosis develop protein-energy malnutrition (PEM) and experience some degree of wasting. Malnutrition is usually caused by a combination of factors (see Table 25-5). Patients may consume less food due to reduced appetite, gastrointestinal symptoms, or fatigue. Ascites often causes early satiety. If the diet is sodium restricted (to treat ascites), meals may seem monotonous or unpalatable. Fat malabsorption is common due to reduced bile flow, which leads to steatorrhea and deficiencies of the fat-soluble vitamins and some minerals. Other GI symptoms, such as diarrhea, vomiting, and gastrointestinal bleeding, contribute to additional nutrient losses. If cirrhosis is a consequence of alcohol abuse, multiple nutrient deficiencies may be present.

Treatment of Cirrhosis

Treatment of cirrhosis is individualized according to the severity of the illness and the complications that develop. Supportive care, including an appropriate diet and

TABLE 25-5 Possible Causes of Malnutrition in Liver Disease

Mechanism	Examples
Reduced nutrient intake	Anorexia, early satiety (due to ascites), nausea and vomiting, restrictive diets, effects of medications (including gastrointestinal disturbances and taste changes), abdominal pain, fatigue, fasting for medical procedures
Malabsorption/nutrient losses	Fat malabsorption (due to reduced bile flow), vomiting, diarrhea, gastrointestinal bleeding, effects of medications (including malabsorption and nutrient losses from diuretic use)
Altered metabolism/increased nutrient needs	Hypermetabolism, catabolism, infections/inflammation, inadequate protein synthesis, reduced nutrient storage and metabolism in the liver

© Garry Watson/Photo Researchers, Inc.

Ascites is caused by different diseases, but cirrhosis is the underlying cause in most patients with this condition.

◆ The aromatic amino acids—phenylalanine, tyrosine, and tryptophan—have carbon rings in their side groups. The branched-chain amino acids are leucine, isoleucine, and valine; their side groups have a branched structure.

avoidance of liver toxins, promotes recovery and helps to prevent further damage. Abstinence from alcohol is critical for preserving liver function and extending survival. Antiviral therapy may be prescribed to treat viral infections. Patients may be screened for life-threatening complications, such as gastroesophageal varices and liver cancer. Liver transplantation may be necessary in advanced cirrhosis.

Drugs are prescribed to treat the symptoms and complications that accompany cirrhosis. Medications for portal hypertension and varices include propranolol and octreotide, which reduce portal blood pressure, and vasopressin, which constricts blood vessels. Diuretics may help to control portal hypertension and ascites; common examples include spironolactone and furosemide. To stimulate the appetite and promote weight gain, megestrol acetate or dronabinol may be prescribed. Drug treatment of hepatic encephalopathy focuses on controlling blood ammonia levels. Lactulose, a nonabsorbable disaccharide often used as a laxative, helps to reduce ammonia production and absorption in the colon. The antibiotic neomycin is an alternative treatment for elevated ammonia that works by altering bacterial populations. The Diet-Drug Interactions feature lists potential nutritional problems associated with these medications.

Medical Nutrition Therapy for Cirrhosis

Nutrition therapy for cirrhosis is customized to each patient's needs, which vary considerably and depend on the accompanying complications. Patients with cirrhosis are generally at high risk of protein-energy malnutrition and muscle wasting; therefore, protein and energy intakes must be high enough to maintain nitrogen balance. Dietary substances that may cause additional liver injury should be avoided; examples include alcohol, certain drugs, herbal supplements, and vitamin or mineral megadoses. Table 25-6 lists the general dietary guidelines for cirrhosis, which are discussed in the sections that follow.

Energy To estimate energy requirements, health practitioners measure or calculate the resting metabolic rate (RMR) and then apply a stress factor, as described in the "How to" on p. 621 (Chapter 18). If possible, indirect calorimetry should be used to

DIET-DRUG INTERACTIONS

Check this table for notable nutrition-related effects of the medications discussed in this chapter.

	Gastrointestinal Effects	Interactions with Dietary Substances	Metabolic Effects
Appetite stimulants (megestrol acetate, dronabinol)	Nausea, vomiting, diarrhea.	—	Hyperglycemia (megestrol acetate).
Diuretics (furosemide, spironolactone[a])	Dry mouth, anorexia, decreased taste perception.	Furosemide's bioavailability is reduced when taken with food.	Fluid and electrolyte imbalances,[a] hyperglycemia (spironolactone), hyperlipidemia (spironolactone), thiamin and zinc deficiencies.
Immunosuppressants (cyclosporine, tacrolimus)	Nausea, vomiting, diarrhea, anorexia (tacrolimus).	Grapefruit juice can raise serum concentrations of these drugs to toxic levels. Cyclosporine potentiates the effects of alcohol. The bioavailability of tacrolimus is reduced when the drug is taken with food.	Electrolyte imbalances, hypertension, hyperglycemia, hyperlipidemia.
Lactulose	Diarrhea.	—	Fluid and electrolyte imbalances.

[a]*Furosemide* is a "potassium-wasting" diuretic; patients should increase intakes of potassium-rich foods. *Spironolactone* is a "potassium-sparing" diuretic; patients should avoid supplemental potassium and potassium-containing salt substitutes.

TABLE 25-6 Medical Nutrition Therapy for Liver Cirrhosis

Energy	• Energy needs may be approximately 20% above resting metabolic rate (RMR); calculate or measure RMR and apply the stress factor 1.2 initially (see Table 18–3 and the "How To" on p. 621). • Use estimated dry body weight for RMR calculations in patients with ascites. • Energy requirements may be higher in patients with infection or malnutrition. Energy requirements may be lower in patients who would benefit from weight loss.
Meal frequency	• To improve food intake, patients should consume small meals 4 to 6 times daily.
Protein	• Provide 0.8 to 1.2 g protein per kilogram of dry body weight per day to maintain nitrogen balance and prevent wasting.
Carbohydrate	• No carbohydrate restrictions unless patient has insulin resistance or diabetes. • For persons with insulin resistance or diabetes, provide up to 50% to 60% of kcalories from carbohydrates (mainly complex carbohydrates); carbohydrate intake should be consistent from day to day and at each meal and snack.
Fat	• No fat restrictions unless fat malabsorption is present. • If fat is malabsorbed, restrict fat to 30% of total kcalories or as necessary to control steatorrhea; use medium-chain triglycerides (MCT) to increase kcalories.
Sodium and fluid	• Restrict sodium as necessary to control ascites; 2000 mg sodium per day is adequate restriction in most cases. • If ascites is accompanied by low serum sodium levels (less than 128 mEq/L), restrict fluids to 1200 to 1500 mL per day. In severe cases (serum sodium less than 125 mEq/L), restrict fluids to 1000 to 1200 mL per day.
Vitamins and minerals	• Ensure adequate intake from diet or supplements based on individual needs.

determine RMR. For most patients with cirrhosis, the stress factor 1.2 can be used initially and adjusted as necessary.[21] Nutrient malabsorption, recent weight loss, and infection can increase energy needs. For patients with ascites, RMR calculations should use either the patient's desirable weight or an estimated dry weight (weight without ascites). A value for dry weight can be obtained after diuretic therapy or after a medical procedure that directly removes excess abdominal fluid.

Many patients with cirrhosis have difficulty consuming enough food to achieve good nutrition status. They may better tolerate four to six daily feedings than three meals per day. Liquid dietary supplements can help to improve energy intakes. The "How to" below offers additional suggestions that can help a patient meet energy needs.

HOW TO Help the Person with Cirrhosis Eat Enough Food

Individuals with cirrhosis often have difficulty consuming enough food to prevent malnutrition and its consequences. Ascites and gastrointestinal symptoms such as nausea and vomiting may interfere with food intake. Fatigue may cause disinterest in food preparation. Sodium restrictions may make foods unpalatable. To improve food intake:

- If nutrient restrictions are necessary, make sure the patient fully understands how to modify the diet so that food intake is not restricted unnecessarily. Provide lists of acceptable foods and menus. Explain how recipes can be altered so that favorite foods can still be incorporated into the diet.
- Suggest between-meal snacks during the day and a snack at bedtime. An oral supplement such as Ensure can substitute for a snack and requires no preparation. Snacks should not be consumed within two hours of meals, or they may reduce appetite at mealtime.
- If the patient has little appetite or is quickly satiated, suggest foods that are higher in food energy, such as whole milk instead of reduced-fat milk or canned fruit that is packed in heavy syrup instead of fruit juice.
- Recommend energy boosters. Cream sauces and gravies can add kcalories to entrées. Fruit juices and fruit nectars can substitute for drinking water. The following additions can boost the energy content of meals:
  - Sour cream and butter—on vegetables and potatoes
  - Mayonnaise—in sandwiches and salads
  - Half-and-half and light cream—in soups and on cereals
  - Hard-boiled eggs—in casseroles and meat loaf
  - Cheese—in salads and casseroles and melted on steamed vegetables
  - Peanut butter, nut butters, and cream cheese—on crackers or celery and in milk shakes
  - Chopped nuts—in salads, cooked cereals, and bakery products

Low-sodium diets are recommended for treating ascites and other medical conditions, including kidney and heart disorders. The "How To" on p. 860 offers suggestions to help patients implement sodium restrictions. To improve the palatability of low-sodium meals:

- Suggest that patients replace the salt they use for cooking and seasoning with strong-flavored herbs and spices such as chili powder, coriander, cumin, curry powder, garlic, ginger, lemon, mint, and parsley.
- Advise patients to check food labels to learn the sodium content of the foods they eat. Similar products may be available that are lower in sodium. (Persons using potassium-sparing diuretics should be cautioned to avoid salt substitutes that replace sodium with potassium.)

Offer support and encouragement to the patient with cirrhosis. Severe weight loss is less likely to occur if dietary advice is provided before problems progress.

◆ Reminder: The protein RDA for healthy adults is 0.8 g/kg.

Protein The protein recommendation is 0.8 to 1.2 grams of protein per kilogram of body weight per day, based on desirable weight or dry weight. ◆ Patients with hepatic encephalopathy should avoid excessive protein consumption, and their protein intake should be spread throughout the day so that they consume only modest amounts at each meal. Protein restriction is not helpful, however, because inadequate protein can worsen malnutrition and wasting. In an attempt to normalize altered amino acid ratios in brain tissue and improve mental status, some health care providers may prescribe enteral formulas with reduced aromatic amino acids and added branched-chain amino acids. Clinical studies testing the use of these formulas have yielded mixed results, however, and their routine use is not currently recommended.[22]

Carbohydrate Carbohydrate provides a substantial proportion of energy needs. Many patients with cirrhosis are insulin resistant and require medications or insulin to manage their hyperglycemia. These individuals should follow the dietary guidelines for diabetes: consume mostly complex carbohydrates, and consume them at regular intervals throughout the day.

Fat Fat provides both energy and essential fatty acids. In patients with fat malabsorption, fat intake may be restricted to less than 30 percent of total kcalories or as necessary to control steatorrhea. Medium-chain triglycerides (MCT) may be used to provide additional energy, although essential fatty acids cannot be obtained from MCT oils and may need to be supplemented. Severe steatorrhea warrants supplementation of the fat-soluble vitamins, calcium, magnesium, and zinc (see Chapter 24).

Sodium and Fluid Patients with ascites are generally advised to restrict sodium. Ascites is partly caused by the kidneys' reabsorption of sodium into the blood, which results in sodium and water retention. Therefore, the treatment usually includes both a moderate sodium restriction (to no more than 2000 milligrams of sodium per day) and diuretic therapy to promote fluid loss. ◆ Potassium intake should be monitored if a potassium-wasting diuretic (such as furosemide) is used.

◆ Table 28-1 (p. 877) and the "How to" on p. 860 provide information about following a sodium-restricted diet.

Many patients find low-sodium diets unpalatable, so some health practitioners may allow a more liberal sodium intake and depend on diuretics to mobilize excess fluids. If patients do not respond to sodium restriction and diuretic therapy, fluid may be removed from the abdomen by surgical puncture **(paracentesis)** or may be diverted to the bloodstream using a catheter **(peritoneovenous shunt).**

Fluid restriction may be necessary when ascites is accompanied by a low concentration of serum sodium. If the sodium level falls below 128 milliequivalents per liter, the fluid intake should be limited to 1200 to 1500 milliliters daily; with a sodium level below 125 milliequivalents per liter, fluids should be restricted to 1000 to 1200 milliliters per day.[23]

Vitamins and Minerals Vitamin and mineral deficiencies are common in patients with cirrhosis due to the effects of illness, disease complications, or the alcohol abuse that may have induced the liver disease. Thus, multivitamin supplementation is often necessary. If steatorrhea is present, fat-soluble nutrients can be provided in a water-soluble form. Patients with esophageal varices may find it easier to ingest supplements in liquid form.

Enteral and Parenteral Nutrition Support In patients who are unable to consume enough food, tube feedings may be infused overnight as a supplement to oral intakes or may replace oral feedings entirely. Although standard formulas are often appropriate, an energy-dense, moderate-protein, low-electrolyte formula may be necessary for patients with ascites or fluid restrictions. In patients with esophageal varices, the feeding tube should be as narrow and flexible as possible to prevent rupture and bleeding. Parenteral nutrition support should be considered for patients who are unable to tolerate enteral feedings due to intestinal obstruction, gastrointestinal bleeding, or uncontrollable vomiting. To avoid excessive fluid delivery, patients with ascites typically require concentrated parenteral solutions, which are infused into central veins. The Case Study on p. 797 allows you to apply your knowledge of cirrhosis to a clinical situation.

paracentesis (pah-rah-sen-TEE-sis): a surgical puncture of a body cavity with an aspirator to draw out excess fluid.

peritoneovenous (PEH-rih-toe-NEE-oh-VEE-nus) **shunt:** a surgical passage created between the peritoneum and the jugular vein to divert fluid and relieve ascites. The peritoneum is the membrane that surrounds the abdominal cavity.

CASE STUDY Carpenter with Cirrhosis

Marty Hamilton, a 49-year-old carpenter, has just been diagnosed with cirrhosis, which is a consequence of his alcohol abuse over the past 25 years. Although he recognizes that he has an alcohol problem and recently entered an alcohol rehabilitation program, he is still drinking. At 5 feet 8 inches tall, Mr. Hamilton, who formerly weighed 160 pounds, now weighs 130 pounds. According to family members, he is showing signs of mental deterioration, such as forgetfulness and an inability to concentrate. He is jaundiced and appears thin, although his abdomen is distended with ascites. Laboratory findings indicate elevated serum concentrations of AST, ALT, and ammonia; reduced albumin levels; and hyperglycemia.

1. Do Mr. Hamilton's laboratory values suggest liver disease? Compare the results of his laboratory tests with the values shown in Table 25-3 (p. 792).
2. From the limited information available, evaluate Mr. Hamilton's nutrition status. What medical problem makes it difficult to interpret his present weight? Describe the development of that type of problem in liver disease, and explain how the diet is usually adjusted for such a patient.
3. Calculate Mr. Hamilton's energy and protein needs. Describe the general diet you might recommend for him. What suggestions do you have for increasing his energy intake?
4. Explain the significance of Mr. Hamilton's elevated blood ammonia levels. What are some signs that would indicate that he is undergoing mental decline?
5. Describe each of the following complications of liver disease: portal hypertension, jaundice, and gastroesophageal varices. What complication may result if the esophageal varices are not treated?

IN SUMMARY

Liver cirrhosis is characterized by extensive fibrosis and permanent liver dysfunction. The primary causes of cirrhosis in the United States are hepatitis C infection and alcohol abuse. Symptoms of cirrhosis include fatigue, gastrointestinal disturbances, anorexia, and weight loss. Complications include portal hypertension, gastroesophageal varices, ascites, and hepatic encephalopathy. Treatment of cirrhosis is highly individualized and depends on the accompanying symptoms and complications. Both drug therapies and dietary adjustments are usually necessary. If warranted, the diet may need to be restricted in fat, sodium, or fluids. A person with cirrhosis often has a poor food intake and is at high risk of malnutrition.

Liver Transplantation

Acute or chronic liver disease can lead to liver failure, in which case liver transplantation is the only remaining treatment option. The most common illnesses that precede liver transplantation are chronic hepatitis C infection and alcoholic liver disease, which account for about 50 percent of liver transplant cases.[24] The 5-year survival rate among transplant recipients ranges from 58 to 81 percent, depending on the cause of illness.[25] Complications such as ascites and hepatic encephalopathy worsen the prognosis.

Nutrition Status of Transplant Patients As mentioned earlier, advanced liver disease is usually associated with malnutrition, which can increase the risk of complications following a liver transplant. Evaluating nutrition status in transplant candidates can be difficult because liver dysfunction and malnutrition often have similar metabolic effects. In addition, fluid retention can mask weight loss and alter anthropometric and laboratory values. Correcting malnutrition prior to transplant surgery can help speed recovery after the surgery.

Posttransplantation Concerns The immediate concerns following a transplant are organ rejection and infection. Immunosuppressive drugs, including prednisone,

cyclosporine, and tacrolimus, help to reduce the immune responses that cause rejection, but they also raise the risk of infection. Infections are a potential cause of death following a liver transplant; therefore, antibiotics and antiviral medications are prescribed to reduce infection risk.

Immunosuppressive drugs can affect nutrition status in numerous ways. Gastrointestinal side effects include nausea, vomiting, diarrhea, abdominal pain, and mouth sores. Some medications may alter appetite and taste perception. Some of the drugs may cause hyperglycemia or outright diabetes, which may need to be controlled with insulin. Electrolyte and fluid imbalances are common. Other possible effects include hypertension, hyperlipidemias, protein catabolism, and increased osteoporosis risk.[26]

Protein and energy requirements are increased after transplantation due to the stress of surgery. High-kcalorie, high-protein snacks and enteral supplements can help the transplant patient meet postsurgical needs. Vitamin and mineral supplementation is also an integral part of nutrition care. To help transplant patients avoid developing foodborne illnesses, health practitioners can provide information about food safety measures, such as cooking meats adequately, washing fresh produce, and avoiding foods that may be contaminated. Highlight 18 (pp. 632–639) provides additional information about food safety.

IN SUMMARY

Liver transplantation has improved the long-term outlook for patients with advanced liver disease. Transplant patients are usually malnourished and may have medical problems that affect transplant success. Due to the potential for organ rejection, immunosuppressive drugs are prescribed following surgery. Use of these drugs increases the risk of infection, and the drugs have side effects that can impair nutrition status and general health.

Gallbladder Disease

As described earlier in this chapter, the gallbladder concentrates and stores the bile produced by the liver until the bile is needed for fat digestion (see Figure 25-3). Disorders that obstruct the liver's release of bile can damage the liver. More commonly, disorders of the biliary system—the gallbladder and bile ducts—result in the formation of **gallstones.** Gallstones affect an estimated 30 million people in the United States, or about 10 percent of the population.[27]

Types of Gallstones

The formation of gallstones, or **cholelithiasis,** results from excessive concentration and crystallization of the compounds in bile. Bile is a solution of bile acids, cholesterol, phospholipids, proteins, and bile pigment (bilirubin). While stored in the gallbladder, bile's concentration increases approximately 10-fold as its water content is extracted. Factors that raise bile's cholesterol concentration, promote crystal formation, or reduce gallbladder motility favor gallstone formation.[28]

gallstones: stones that form in the gallbladder from crystalline deposits of cholesterol or bilirubin.

cholelithiasis (KOH-leh-lih-THIGH-ah-sis): formation of gallstones.
- **chole** = bile
- **lithiasis** = formation of stones

sludge: literally, a semisolid mass. Biliary sludge is made up of mucus, cholesterol crystals, and bilirubin granules.

Cholesterol Gallstones In about 80 percent of cases, the gallstones are composed primarily of cholesterol, although they also contain calcium salts and bilirubin. The cholesterol in bile precipitates out of solution and forms small crystals, which eventually coalesce to form stones. The stones can be as small as a pea or as large as a Ping-Pong ball. Some people tend to form many small stones, while others may form only one or two large ones.

Cholesterol gallstones often develop because the bile concentrate thickens and forms a **sludge** that cannot be easily expelled by gallbladder contraction. Biliary

FIGURE 25-3 The Gallbladder and Bile Ducts

Most gallstones are made primarily of cholesterol; they can be as small as a pea or as large as a Ping-Pong ball.

sludge frequently develops after rapid weight loss, gastric bypass surgery, and long-term total parenteral nutrition and also occurs during pregnancy.

Pigment Gallstones Pigment stones account for 10 to 25 percent of gallstone cases in the United States, although they are much more common in Asian countries.[29] Pigment stones are primarily made up of the calcium salt of bilirubin (calcium bilirubinate). They often develop as a result of bacterial infection, which alters bilirubin and causes it to precipitate out of bile and form stones. Other cases result from excessive red blood cell breakdown, leading to an abnormal accumulation of bilirubin. Conditions associated with pigment stone formation include biliary tract infections, pancreatitis, and red blood cell disorders, such as sickle-cell anemia. Pigment stones may form in either the gallbladder or a bile duct. Unlike the crystalline cholesterol stones, pigment stones are soft and easily crushed.

Consequences of Gallstones

About 85 percent of gallstones are asymptomatic and are discovered accidentally while testing for other conditions.[30] However, many people experience an aggressive course of illness with recurring symptoms.

Gallstone Symptoms Gallstone pain usually arises when a gallstone temporarily blocks the cystic duct, which leads from the gallbladder to the common bile duct (see Figure 25-3). The pain is steady and severe and may last for several minutes or several hours. Although the pain is usually located in the upper abdomen, it may radiate to the chest or to the back. Nausea, vomiting, and bloating may also be present. Symptoms usually develop after meals, especially after eating fatty foods. Pain may also occur during the night and awaken a person from sleep.

Complications of Gallstones If a gallstone remains lodged in the cystic duct, it can obstruct bile flow to the duodenum and cause **cholecystitis**—distention and inflammation of the gallbladder. Cholecystitis can lead to infection or to more severe complications, including perforation of the gallbladder, **peritonitis,** and fistulas. If gallstones obstruct the common bile duct (see Figure 25-3), they can block bile flow from the liver and lead to jaundice or damage to liver tissue. An impacted stone within the bile ducts may lead to infection and the condition known as **bacterial cholangitis,** which causes severe pain, sepsis, and fever and is

cholecystitis (KOH-leh-sih-STY-tis): inflammation of the gallbladder, usually caused by obstruction of the cystic duct by gallstones.

peritonitis: inflammation of the peritoneal membrane, which lines the abdominal cavity.

bacterial cholangitis (KOH-lan-JYE-tis): bacterial infection involving the bile ducts.

often a medical emergency. Gallstones can block the pancreatic duct as well—a primary cause of acute pancreatitis. Due to the potential danger of these complications, individuals should seek medical attention if gallstone pain does not resolve over time or if fever, jaundice, or persistent nausea and vomiting develop.

Risk Factors for Gallstones

Gallstone risk is influenced by a number of genetic and lifestyle factors. As described in the sections that follow, the risk factors are typically related to increased cholesterol concentrations in bile or reduced gallbladder motility, which promote crystallization and subsequent gallstone formation.

Ethnicity Although the genetic factors related to gallstone formation are not yet clear, ethnicity strongly influences gallstone formation. The Pima Indians are an exceptionally high-risk population; gallstones develop in about 70 percent of adult women. Other high-risk populations include Native Americans in the United States and Canada, Scandinavians, Chileans, and Bolivians. In the United States, African Americans have a lower prevalence of gallstones than white populations.[31]

Aging Because gallstones cannot dissolve spontaneously, gallstone prevalence increases with age. Moreover, bile composition tends to change with aging: the cholesterol concentration increases while bile acids decrease, leading to a greater likelihood of cholesterol crystallization.

Gender The incidence of gallstones in women is nearly three times that in men during the reproductive years, although it falls to a similar level after menopause.[32] The reason for the gender difference is that estrogen alters cholesterol metabolism and causes an increased secretion of cholesterol into bile. The use of estrogen replacement therapy after menopause increases gallstone risk in postmenopausal women.

Pregnancy Some women experience their first gallstone symptoms during pregnancy. Gallstone risk is increased in pregnancy due to hormonal changes: higher serum estrogen levels increase the secretion of cholesterol into bile, and higher progesterone levels impair gallbladder motility.[33]

Obesity and Weight Loss Obesity is associated with increased cholesterol synthesis in the liver, leading to a greater release of cholesterol into bile. In a clinical study that investigated the incidence of gallstones among women of different weights, researchers found that the women who had a body mass index (BMI) greater than 45 had a risk of gallstone formation seven times that of the nonobese women.[34] ◆

◆ Reminder: A healthy weight usually falls between a BMI of 18.5 and 25.0. Overweight and obesity are usually defined by BMIs above 25 and 30, respectively.

Gallstones frequently develop as a result of rapid weight loss, occurring in about 25 percent of obese persons on very-low-kcalorie diets and in as many as half of individuals who undergo gastric bypass surgery.[35] Dieting increases the secretion of cholesterol into bile and may also decrease gallbladder motility. The oral ingestion of bile salts has been shown to reduce the risk of gallstone formation during rapid weight loss.

Other Risk Factors Long-term total parenteral nutrition usually reduces gallbladder motility, increasing the development of biliary sludge. Some medications (such as octreotide) may have similar effects. The medication clofibrate, used for heart disease, increases the cholesterol concentration of bile, promoting crystallization. High triglyceride levels in blood are also associated with increased gallstone risk, as are hyperinsulinemia, insulin resistance, and diabetes mellitus.

Treatment for Gallstones

Asymptomatic gallstones generally do not require treatment. Gallstones that cause symptoms or complications are usually treated by gallbladder surgery or by nonsur-

gical procedures that dissolve or fragment the stones. To minimize symptoms before the gallbladder or gallstones are removed, a low-fat diet (with less than 30 percent of total kcalories from fat) may be prescribed.[36]

Surgery Gallbladder removal, or **cholecystectomy,** is the primary treatment for patients with recurring gallstones.[37] The preferred surgical approach is a **laparoscopic** method, which relies on narrow surgical telescopes (laparoscopes) to view and perform the necessary procedures via small incisions in the abdomen. The procedure takes only one or two hours, and many patients are discharged on the same day as the surgery. In patients with complications that make organ removal difficult, open cholecystectomy may be performed. In this procedure, the surgeon cuts through the abdominal muscle and exposes the abdominal cavity, allowing direct access to the gallbladder and bile ducts. An open cholecystectomy is associated with a greater risk of infection, more pain, and a lengthier recovery time than the laparoscopic procedure.

Once the gallbladder has been removed, the common bile duct collects bile between meals and releases it into the duodenum at mealtimes. Most patients have no problems after they recover from surgery, although some may experience diarrhea, abdominal pain, and other gastrointestinal symptoms. The diarrhea may result from an increased amount of bile in the large intestine, which has a laxative effect. Abdominal pain is sometimes caused by the presence of residual stones within the common bile duct that were overlooked during surgery or that formed within the duct itself. Bile duct injuries occasionally result from the surgical procedure.

Nonsurgical Procedures Nonsurgical methods are used primarily in patients who have small cholesterol stones and transient conditions associated with gallstone formation. The gallstones can be treated by oral intake of ursodeoxycholic acid (ursodiol), a bile acid that reduces cholesterol secretion by the liver and eventually causes the cholesterol crystals in gallstones to dissolve. Ursodeoxycholic acid must be used for 6 to 12 months and is best suited for stones that are 5 millimeters (about $^1/_4$ inch) in diameter or smaller. Recurrence rates after dissolution are as high as 50 percent.[38]

Cholesterol gallstones can be fragmented using **shock-wave lithotripsy**, a procedure that is also used to fragment kidney stones. This technique uses high-amplitude sound waves (called shock waves) to break gallstones into pieces that are small enough to either pass into the intestine or be dissolved with ursodeoxycholic acid. Shock-wave lithotripsy can be performed only in patients with few gallstones. Success is highest in patients with solitary stones that are less than 20 millimeters ($^3/_4$ inch) in diameter. Recurrence of gallstones has been reported in up to 44 percent of patients using this procedure.[39]

IN SUMMARY

Gallstones are the most common disorder affecting the gallbladder. They are formed by the concentration of compounds in bile, especially cholesterol and the bile pigment bilirubin. Most people with gallstones have no symptoms. Symptomatic gallstones can cause recurring pain and gastrointestinal problems that usually appear after meals and may persist for several hours. The risk of gallstone formation increases with age and is highest in premenopausal and pregnant women and in persons who are obese or who undergo rapid weight loss. Treatments for gallstones include gallbladder removal and gallstone dissolution or fragmentation.

cholecystectomy (KOH-leh-sis-TEK-toe-mee): surgical removal of the gallbladder.

laparoscopic: pertaining to procedures that use a laparoscope for internal examination or surgery. A laparoscope is a narrow surgical telescope that is inserted into the abdominal cavity through a small incision. A video camera is usually attached so that the procedure can be viewed on a television monitor.

shock-wave lithotripsy: a nonsurgical procedure that uses high-amplitude sound waves to fragment gallstones.

Clinical Portfolio

1. Vijaya Reddy is a college student who visited relatives near her parents' birthplace in Anantapur, India, during summer vacation. Although her relatives provided boiled or purified water at their home, they occasionally took Vijaya to local restaurants, where she drank tap water. Several weeks after Vijaya returned home, she developed flulike symptoms and started feeling extremely tired. She also experienced upper abdominal pain and felt nauseous after meals. After her roommate told her that her eyes and skin appeared yellow, she knew something was definitely wrong. A physician at the student health center diagnosed hepatitis.
   - Which type of hepatitis did Vijaya most likely have?
   - What additional symptoms can develop? Is Vijaya's condition likely to become chronic?
   - What medical treatment is suggested for Vijaya's condition? Describe the dietary modifications that may be necessary in some cases.
2. As discussed in the section on cirrhosis, many patients develop protein-energy malnutrition and wasting during the course of illness. Review Table 25-5 to find examples of problems that may lead to malnutrition. Select three nutrition or medical problems (from the "Examples" column), and discuss the complications of liver disease that may cause the problems you selected. What dietary or medical treatments can help in managing these problems?

NUTRITION ON THE NET

For further study of topics covered in this chapter, log on to **academic.cengage.com/nutrition/rolfes/UNCN8e**. Go to Chapter 25, then to Nutrition on the Net.

NUTRITION ASSESSMENT CHECKLIST for People with Disorders of the Liver and Gallbladder

Medical History

Check the medical record to determine:

- Type of liver disorder
- Cause of the liver disorder
- If the patient has received a liver transplant
- If the patient has a history of gallstones

Review the medical record for complications that may alter nutritional needs, including:

- Abdominal pain
- Anemia
- Ascites
- Esophageal varices
- Hepatic encephalopathy
- Impaired kidney or lung function
- Infections
- Insulin resistance or diabetes mellitus
- Malabsorption
- Malnutrition
- Pancreatitis

Medications

In patients with liver dysfunction, the risk of diet-drug interactions is high because most drugs are metabolized in the liver. Risk of interactions is intensified for patients with:

- Ascites (medications may take a long time to reach the liver)
- Renal failure (medications are often metabolized further in the kidneys and excreted in the urine)
- Malnutrition
- Multiple prescriptions
- Long-term medication use

Dietary Intake

For patients with fatty liver, pay special attention to:

- Energy intake, if the patient is overweight or malnourished, has diabetes, or is receiving total parenteral nutrition
- Carbohydrate intake, if the patient has diabetes or is receiving total parenteral nutrition
- Alcohol abuse

For patients with hepatitis, cirrhosis, or ascites:

- Check appetite.
- Ensure that energy and nutrient intakes are adequate.
- Determine alcohol consumption.
- Determine whether sodium or fluid restriction is warranted.
- Base energy needs on desirable weight or estimated dry weight to avoid overfeeding.

Anthropometric Data

Take baseline height and weight measurements, and monitor weight regularly. For patients with ascites and edema:

- Monitor weight changes to evaluate the degree of fluid retention.
- Remember that the patient may be malnourished, and weight may be deceptively high.

Laboratory Tests

Note that albumin and serum proteins are often reduced in people with liver disease and cannot always be used as indicators of nutrition status. Review the following laboratory test results to assess liver function:

- Albumin
- Alkaline phosphatase
- ALT and AST
- Ammonia
- Bilirubin
- Prothrombin time

Check laboratory test results for complications associated with liver failure, including:

- Anemia
- Decreased renal function
- Fluid retention
- Hyperglycemia

Physical Signs

Look for physical signs of:

- Fluid retention (ascites and edema)
- PEM (muscle wasting and unintentional weight loss)
- Nutrient deficiencies

STUDY QUESTIONS

CENGAGENOW™

To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Describe fatty liver, and identify its possible causes. What consequences of fatty liver may develop? What are possible treatments? (pp. 788–789)
2. What is hepatitis, and what are its primary causes? Compare the features of infection with hepatitis virus A, B, and C. Identify nutritional concerns for patients with hepatitis. (pp. 789–790)
3. Describe the progression of liver disease to cirrhosis. What are the most common causes of cirrhosis in the United States? (pp. 790–791)
4. Discuss the consequences of cirrhosis, including its clinical effects and complications such as portal hypertension, gastroesophageal varices, ascites, and hepatic encephalopathy. What metabolic changes may result from altered liver function? (pp. 791–793)
5. How does cirrhosis affect nutrition status? Describe the dietary treatment of a patient with cirrhosis. Discuss the special dietary concerns of patients with ascites and esophageal varices. (pp. 793–797)
6. Discuss the problems that arise following liver transplantation that can affect nutrition status. What dietary modifications may be necessary? (pp. 797–798)
7. Explain how gallstones form, and describe the features of the two main types of gallstones. What complications are associated with gallstone disease? (pp. 798–800)
8. Discuss the major risk factors for gallstone disease. Describe the primary methods of treatment. (pp. 800–801)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 805.

1. Which of the following dietary strategies would be the most appropriate for reversing fatty liver associated with diabetes mellitus?
   a. following a low-protein diet
   b. following a fat-restricted diet
   c. following a fluid- and sodium-restricted diet
   d. modifying energy to achieve a desirable weight and modifying carbohydrates to attain blood glucose control
2. Which of the following statements about hepatitis is true?
   a. Chronic hepatitis can progress to cirrhosis.
   b. Whatever the cause of hepatitis, symptoms are typically severe.
   c. People with hepatitis require high-kcalorie, high-protein diets.
   d. HCV infection can be spread through contaminated foods and water.
3. Esophageal varices are a dangerous complication of liver disease primarily because they:
   a. interfere with food intake.
   b. can lead to massive bleeding.
   c. divert blood flow from the GI tract.
   d. contribute to hepatic encephalopathy.
4. A complication of liver disease that contributes to the development of ascites is:
   a. portal hypertension.
   b. rising blood ammonia levels.
   c. elevated serum albumin levels.
   d. insulin resistance.
5. A patient with cirrhosis may develop personality changes and motor dysfunction, which are signs of:
   a. jaundice.
   b. hepatic encephalopathy.
   c. hyperammonemia.
   d. hepatic coma.
6. With respect to protein intake, patients with cirrhosis should:
   a. consume no more than the protein RDA.
   b. restrict protein intake to 0.6 gram per kilogram of body weight.
   c. use formulas enriched with aromatic amino acids to meet their protein needs.
   d. maintain nitrogen balance by consuming 0.8 to 1.2 grams of protein per kilogram of body weight per day.
7. People with ascites must often restrict dietary intake of:
   a. fat.
   b. protein.
   c. sugars.
   d. sodium.
8. Dietary concerns after a liver transplant include all of the following *except:*
   a. severe protein restrictions that are difficult to adhere to.
   b. increased risk of foodborne illness.
   c. gastrointestinal side effects of medications.
   d. reduced appetite and altered taste perception from medications.
9. Regarding risk factors for gallstone disease:
   a. prevalence is much higher in men than in women.
   b. gallstone risk is increased during pregnancy.
   c. rapid weight loss can temporarily shrink gallstones.
   d. risk is generally similar among ethnic groups.
10. Nonsurgical approaches to gallstone treatment include:
    a. cholecystectomy.
    b. weight loss.
    c. dissolution and fragmentation.
    d. immunosuppressant drug therapy.

Food Allergies

© ISM/Phototake

Some of the diseases discussed in this book involve adverse reactions to specific foods. Chapter 15 explained that such responses can be categorized either as *food allergies,* which elicit an immune response, or *food intolerances,* which are caused by other physiological processes. Celiac disease and dermatitis herpetiformis, for example, are characterized by allergic reactions to gluten, whereas lactose intolerance, a result of lactase deficiency, is a type of food intolerance. This highlight focuses on the diagnosis and treatment of food allergies, beginning with a brief review of the body's reactions to an **allergen.** The accompanying glossary defines the relevant terms.

A Review of Food Allergy

A food allergy occurs when a food component, usually an incompletely digested protein, is absorbed into the blood and elicits an immune response.[1] The allergen is treated as a foreign particle that needs to be neutralized, and allergen-specific antibodies are produced to mount a defense. These antibodies are attached to specialized cells (mast cells and basophils) that release inflammatory mediators when they encounter the allergen. The mediators circulate in the blood and may trigger symptoms in the GI tract, skin, respiratory system, and circulatory system. The foods most likely to cause an allergy include eggs, fish, milk, peanuts, shellfish, soybeans, tree nuts, and wheat.[2]

Common symptoms of food allergies include skin rashes, itching, abdominal pain, vomiting, and diarrhea. **Hives** occur frequently; these raised, swollen patches of skin or mucous membranes are associated with intense itching. The most dangerous effect of allergy is **anaphylaxis,** a systemic (whole-body) reaction that may cause difficulty breathing and a dangerous fall in blood pressure, potentially leading to shock. People whose food allergies are intense enough to cause anaphylaxis are often prescribed epinephrine, which they can self-inject in an emergency.

Contact dermatitis or hives can also develop on skin after physical contact with food. In the condition known as **oral allergy syndrome,** hives, swelling, and itching are mostly confined to the lips, tongue, mouth, and throat. These symptoms usually develop following the consumption of raw fruits and vegetables.[3]

Diagnosis of Food Allergy

If a food allergy is suspected, an accurate diagnosis can help a person avoid unnecessary dietary restrictions. Parents who believe that a food allergy is causing health or behavioral problems may limit their children's food intakes, which can adversely affect growth and nutrition status.[4] A timely diagnosis can also help a person avoid accidental exposure to a food allergen.

Diagnosis often requires a thorough medical history, physical examination, and laboratory tests. The medical history can help to establish whether the symptoms are a response to a true food allergy rather than a food intolerance, foodborne illness, or food toxicity. To help pinpoint the foods that cause symptoms, patients are generally advised to keep a **food and symptom diary,** which provides a record of the foods consumed, the amounts, and the symptoms that develop. Other helpful data include the brands of foods consumed, ingredient lists of packaged

GLOSSARY

allergen: a substance that triggers an allergic response.

anaphylaxis: a severe allergic reaction that may include gastrointestinal upset, skin reactions, respiratory symptoms, and low blood pressure, potentially leading to shock.

cross-reactivity: an antibody reaction involving an antigen other than the one that induced the antibody's formation.

food and symptom diary: a food record kept by a patient to determine the cause of an adverse reaction; includes the specific foods and beverages consumed, symptoms experienced, and the timing of meals and symptom onset.

hives: an allergic reaction characterized by raised, swollen patches of skin or mucous membranes that are associated with intense itching; also called *urticaria.*

oral allergy syndrome: an allergic response in which symptoms of hives, swelling, or itching occur only in the mouth and throat; usually a short-lived response that resolves quickly.

Reminder: A *food allergy* is an adverse reaction to food that involves an immune response; also called *food hypersensitivity*. A *food intolerance* is an adverse reaction to food that does not involve an immune response.

A *false-positive* test result indicates that a condition is present (a positive result) when in fact it is not (therefore, it is a false result). Conversely, a *false-negative* test result indicates that a condition is not present (a negative result) when in fact it is (therefore, it is a false result).

foods, and the exact timing of symptom onset. If the symptoms arise several hours or days after the offending food is ingested, the exact cause of the allergy may be more difficult to identify.

Oral Food Challenges

When performed properly, food challenges are considered the gold standard for diagnosing food allergy. In an oral challenge, a food suspected to cause allergy is presented to a patient in a dose suggested by the medical history. If the test substance does not cause symptoms, the challenge is repeated to rule out a false-negative result. Ideally, food challenges are double blinded and placebo controlled: test foods are mixed into other foods or provided in capsules, and placebos are identical in appearance, taste, and texture. A food challenge can be labor intensive and cannot be performed if a patient has a history of severe anaphylaxis.

Elimination Diets

In an elimination diet, the patient omits common food allergens from the diet until symptoms subside, and then reintroduces individual foods one by one. Although foods that cause symptoms are sometimes easily identified using this method, it may be difficult to identify allergens when they are ingredients in packaged foods. Also, allergic reactions sometimes persist for some time after the allergens are removed from the diet; in these cases, an elemental formula diet (which contains no intact proteins) may be needed to stabilize the patient before foods are reintroduced.

Skin-Prick Testing

The skin-prick test evaluates the patient's responses to commercially prepared food extracts that are introduced into the skin (see the photo). Substances that cause areas of redness and swelling greater than 3 millimeters in diameter are considered possible allergens, and larger responses suggest a greater potential for allergy. Although the rate of false-positive results for skin tests is about 50 percent (meaning that half of the reactions that appear to be positive are actually negative), the absence of a reaction is fairly good evidence that the test substance is not the cause of allergy.

© SIU/Visuals Unlimited

In a skin-prick test, extracts containing food allergens are placed on the skin, and the skin is pricked using a lancet or needle. This technique introduces small amounts of the allergens into the skin.

Antibody Blood Testing

Measures of food-specific serum antibodies are useful for assessing the presence of food allergies; generally, a high antibody level suggests an increased risk of an allergic response to a food. Because a person with low antibody levels may still experience an allergic reaction, however, antibody test results need to be considered along with other methods of diagnosis.

Treatment of Food Allergy

Food allergies are treated by eliminating all dietary sources of an allergen. Successful treatment depends in part on the patient's ability to identify hidden sources of allergens in foods with multiple ingredients (see Table H25-1). Inadvertent ingestion of

TABLE 25-1 Food Avoidance in Milk, Egg, and Peanut Allergies

Food Allergy	Excluded Food Ingredients	Hidden Sources
Milk allergy	Milk (including dried, evaporated, and condensed milks), milk solids, buttermilk, yogurt, cheese, butter, artificial butter flavor, half-and-half, cream, whipped cream, custard, pudding, ice cream, casein (or caseinates), whey, protein hydrolysates, lactalbumin, lactoferrin, lactoglobulin.	Margarine, luncheon meats, frankfurters and sausages, high-protein products (including bars, flours, and beverages), nougat candy, chocolate bars, caramel color or flavorings, coffee whiteners, bakery glazes, salad dressings, sauces. Meats sliced at a delicatessen are subject to cross-contamination from sliced cheeses.
Egg allergy	Eggs (including powdered eggs and egg substitutes), egg white, eggnog, meringue, albumin, globulin, lysozyme, ovalbumin, ovoglobulin, ovomucin, ovomucoid, ovotransferrin, ovovitellin, lecithin (some food labels may indicate that a "binder" or "emulsifier" was added).	Many baked products and baking mixes, noodles and pastas, mayonnaise, béarnaise and hollandaise sauces, breaded meats and vegetables, candies, fondants, marshmallows, frozen desserts, ice cream, custards and puddings, frankfurters and sausages, processed meats, cocoa drinks, salad dressings, bakery glazes.
Peanut allergy	Peanuts (also called ground nuts), peanut butter, peanut flour, nut pieces, mixed nuts, beer nuts, artificial nuts, mandalona nuts, peanut sauces (common in Asian cuisine), hydrolyzed vegetable protein (HVP), cold-pressed or gourmet peanut oils (may contain peanut residue).	Chocolate and candy bars, power bars, marzipan, nougat, breakfast cereals, egg rolls, satay sauce, curries, salad dressings. Cross-contamination is possible from food-processing equipment; caution is required when purchasing baked products, ice creams, candies, nut butters, and sunflower seeds.

allergens often occurs because foods become contaminated during meal preparation or food processing. Problem foods may also be consumed at restaurants, schools, and other public places, where the foods' ingredients are not always obvious. The foods that account for most allergic reactions in infants and children are cow's milk, eggs, and peanuts[5]; the dietary issues involved with these foods are described in the sections that follow.

Milk Allergy

Milk and the proteins derived from milk are common ingredients in many prepared and packaged foods, so people with milk allergies must check ingredient lists carefully. As an example, foods that are labeled "nondairy" (such as nondairy creamers) may contain the milk protein casein. In addition, individuals with milk allergies need to avoid milk from all animals due to the potential for **cross-reactivity.** Obtaining sufficient calcium and vitamin D from nonmilk sources may be difficult, and supplementation is often warranted. A milk allergy may be difficult to differentiate from lactose intolerance because both conditions can produce gastrointestinal symptoms.

Egg Allergy

Eggs and egg proteins are common ingredients in many recipes and processed foods; Table H25-1 lists terms that may be used on food labels when egg protein is present. People with egg allergy should avoid eggs from all birds to prevent cross-reactivity. Because flu vaccines are prepared using egg embryos, people with egg allergies need to check with their physicians before being vaccinated.

Peanut Allergy

Some people with peanut allergies have severe reactions, including anaphylaxis, to even the smallest quantities of peanuts. Although peanut allergy is not ordinarily associated with other nut allergies, patients may be advised to avoid all nuts due to potential contamination from food-processing equipment (see Table H25-1). Parents often fear that skin contact with peanut butter or inhalation of peanut dust may cause severe allergic reactions, but there is little evidence that this occurs.[6]

Reevaluation of Food Allergy

Due to the stringent dietary restrictions required for some food allergies, health care providers advise that patients with these allergies be reevaluated periodically so that they do not continue the restrictions unnecessarily. Most young children outgrow food allergies within three to five years, and many older children and adults also lose their allergies in time.[7] Individuals with allergies to peanuts, tree nuts, and seafood are least likely to develop tolerance. Reevaluation may require oral food challenges and skin-prick tests, although substantial caution is necessary in patients who experienced severe allergic reactions after consuming certain foods.

Nutrition in the Clinical Setting

Diabetes is often a silent disease. The dangerous effects of high blood glucose can take decades to develop, a characteristic that causes some people to ignore their condition and disregard treatment. If complications develop, there is no way to correct the damage to heart, kidneys, nerves, and eyes that has occurred. Because most diabetes care requires self-management, the challenge for health practitioners is to motivate patients to make the dietary and lifestyle changes that are necessary. The good news is that careful management allows individuals with diabetes to live long, healthy, and productive lives.

CHAPTER 26

Diabetes Mellitus

CHAPTER OUTLINE

Overview of Diabetes Mellitus • Symptoms of Diabetes Mellitus • Diagnosis of Diabetes Mellitus • Types of Diabetes Mellitus • Prevention of Type 2 Diabetes Mellitus • Acute Complications of Diabetes Mellitus • Chronic Complications of Diabetes Mellitus

Treatment of Diabetes Mellitus • Treatment Goals • Evaluating Diabetes Treatment • Body Weight Concerns • Medical Nutrition Therapy: Nutrient Recommendations • Medical Nutrition Therapy: Meal-Planning Strategies • Insulin Therapy • Antidiabetic Drugs • Physical Activity and Diabetes Management • Sick-Day Management

Diabetes Management in Pregnancy • Pregnancy in Type 1 or Type 2 Diabetes • Gestational Diabetes

HIGHLIGHT 26 The Metabolic Syndrome

The incidence of **diabetes mellitus** ◆ is steadily increasing in the United States and many other countries (see Figure 26-1 on p. 812). The condition affects an estimated 10.2 percent of adults aged 20 and older in the United States, or more than 30 million people.[1] About 28 percent of persons with diabetes are unaware that they have it,[2] a danger because its damaging effects often occur before symptoms develop. Diabetes ranks sixth among the leading causes of death in the United States. It also contributes to the development of other life-threatening diseases, including heart disease and kidney failure, which are discussed in the two chapters that follow. The glossary on p. 812 defines diabetes-related symptoms and complications.

◆ An unrelated condition with a similar name is *diabetes insipidus,* a pituitary disorder that causes a deficiency of antidiuretic hormone.

Overview of Diabetes Mellitus

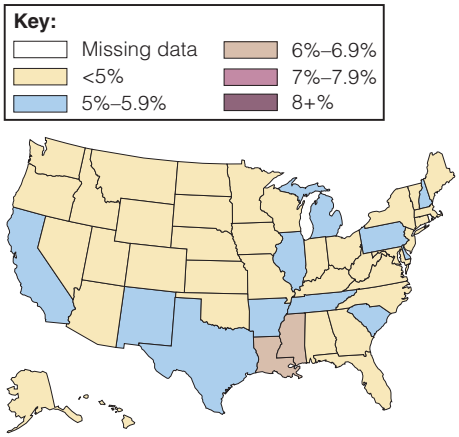
The term *diabetes mellitus* refers to metabolic disorders characterized by elevated blood glucose concentrations and disordered insulin metabolism. People with diabetes may be unable to secrete sufficient insulin or use insulin effectively, or they may have both types of abnormalities. ◆

◆ Reminder: *Insulin* is a pancreatic hormone that regulates blood glucose concentrations. Its actions are countered mainly by the hormone *glucagon.*

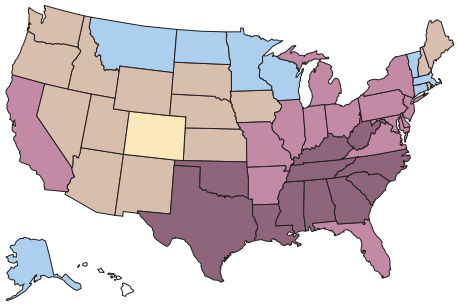
Normally, insulin secretions rise after food is ingested, and the insulin enables muscle and adipose cells to take up newly absorbed glucose from the blood. Insulin is also secreted between meals in smaller amounts to restrain the glucose-raising actions of glucagon, a hormone that promotes glucose production in the liver (gluconeogenesis) and the breakdown of liver glycogen. In diabetes, insulin secretion may be impaired, cells that are normally responsive to insulin may become resistant to its effects, or both. This situation leads to the reduced utilization of glucose in muscle and adipose cells and unrestrained gluconeogenesis in the liver. The result is **hyperglycemia,** a marked elevation in blood glucose levels that can ultimately cause damage to blood vessels, nerves, and tissues. Because insulin also promotes the synthesis of triglycerides and protein in body cells, a defect in insulin metabolism leads to the degradation of these nutrients, an increase

diabetes (DYE-ah-BEE-teez) **mellitus:** a group of metabolic disorders characterized by hyperglycemia and disordered insulin metabolism.
- **diabetes** = siphon (in Greek), referring to the excessive passage of urine that is characteristic of untreated diabetes
- **mellitus** = sweet, honey-like

FIGURE 26-1 Prevalence of Diabetes among Adults in the United States



1994: 36 states had a diabetes prevalence of less than 5% and no state had a prevalence of 7% or greater.



2005: Only 1 state had a diabetes prevalence of less than 5%, and 25 states had a prevalence of 7% or greater.

in fatty acid and triglyceride levels in the blood, and muscle wasting. Table 26-1 summarizes the effects of insulin insufficiency on nutrient metabolism in the body.

Symptoms of Diabetes Mellitus

Symptoms of diabetes (see Table 26-2) are usually related to the degree of hyperglycemia present. When the plasma glucose concentration rises above about 200 milligrams per deciliter (mg/dL), it exceeds the **renal threshold,** which is the concentration at which the kidneys begin to pass glucose into the urine **(glycosuria).** The presence of glucose in the urine draws additional water from the blood, increasing the amount of urine produced. Thus the symptoms that arise in diabetes typically include frequent urination **(polyuria),** dehydration, and increased thirst **(polydipsia).** Some people lose weight and have an increased appetite **(polyphagia)** as a result of the nutrient depletion that occurs when insulin is deficient. Another potential consequence of hyperglycemia is blurred vision, which is caused by the exposure of eye tissues to hyperosmolar fluids. ◆ Increased infections are common in individuals with diabetes and may be due to hyperglycemia, impaired circulation, or weakened immune function. In some cases, constant fatigue is the only symptom and may be related to altered energy metabolism, dehydration, or other effects of the disease.

Diagnosis of Diabetes Mellitus

The diagnosis of diabetes is based primarily on plasma glucose levels, which can be measured under fasting conditions or at random times during the day. ◆ In some cases, an **oral glucose tolerance test** is given: the individual ingests a 50- or 75-gram glucose load, and plasma glucose is measured at one or more time intervals following glucose ingestion. The following criteria are currently used to diagnose diabetes:

- The plasma glucose concentration of a blood sample obtained at a random time during the day (without regard to food intake) is 200 mg/dL or greater,

GLOSSARY OF DIABETES-RELATED SYMPTOMS AND COMPLICATIONS

acetone breath: a distinctive fruity odor on the breath of a person with ketosis.

claudication (CLAW-dih-KAY-shun): pain in the legs while walking; usually due to an inadequate supply of blood to muscles.

dawn phenomenon: morning hyperglycemia that is caused by the early-morning release of growth hormone, which counteracts insulin's glucose-lowering effects.

diabetic coma: a coma that occurs in uncontrolled diabetes; may be due to diabetic ketoacidosis, the hyperosmolar hyperglycemic state, or severe hypoglycemia.

diabetic nephropathy (neh-FRAH-pah-thee): damage to the kidneys that results from long-term diabetes.

diabetic neuropathy (nur-RAH-pah-thee): complications of diabetes that cause damage to nerves.

diabetic retinopathy (REH-tih-NAH-pah-thee): retinal damage that results from long-term diabetes.

gangrene: death of tissue due to a deficient blood supply and/or infection.

gastroparesis (GAS-troe-pah-REE-sis): delayed stomach emptying.

glycosuria (GLY-co-SOOR-ee-ah): an abnormal amount of glucose in urine.

hyperglycemia: elevated blood glucose concentrations. Normal fasting plasma glucose is less than 100 mg/dL. Fasting plasma glucose from 100 to 125 mg/dL suggests prediabetes; values of 126 mg/dL and above suggest diabetes.

hyperosmolar hyperglycemic state: extreme hyperglycemia associated with hyperosmolar blood, dehydration, and altered mental status; formerly called **hyperglycemic hyperosmolar nonketotic coma.**

hypoglycemia: abnormally low concentrations of blood glucose. In diabetes, hypoglycemia is treated when plasma glucose levels fall below 70 mg/dL.

ketoacidosis (KEY-toe-ass-ih-DOE-sis): an acidosis (lowering of blood pH) that results from the excessive production of ketone bodies.

ketonuria (KEY-toe-NOOR-ee-ah): the presence of ketone bodies in the urine.

macrovascular complications: disorders that affect the large blood vessels, including the coronary arteries and arteries of the limbs.

microalbuminuria: the presence of albumin (a blood protein) in the urine, a sign of diabetic nephropathy.

microvascular complications: disorders that affect the small blood vessels and capillaries, including those in the retinas and kidneys.

polydipsia (POL-ee-DIP-see-ah): excessive thirst.

polyphagia (POL-ee-FAY-jee-ah): excessive appetite or food intake.

polyuria (POL-ee-YOOR-ree-ah): excessive urine secretion.

rebound hyperglycemia: hyperglycemia that results from the release of counterregulatory hormones following nighttime hypoglycemia; also called the **Somogyi phenomenon.**

TABLE 26-1 Effects of Insulin Insufficiency on Nutrient Metabolism

Insulin normally promotes nutrient uptake after meals, as well as the synthesis of glycogen, triglycerides, and protein in liver, adipose, and muscle tissue. A defect in insulin metabolism inhibits these processes, leading to the effects shown in this table.

Nutrient	Effects of Insulin Insufficiency
Carbohydrate	• Decreased glucose uptake by muscle and adipose tissue • Decreased glycogen synthesis in muscle and liver • Increased glycogen breakdown in muscle and liver • Increased gluconeogenesis in the liver • Hyperglycemia
Fat	• Decreased triglyceride synthesis in adipose tissue • Increased triglyceride breakdown in adipose tissue • Increased fatty acid and triglyceride levels in the blood • Increased production of ketone bodies in the liver
Protein	• Decreased amino acid uptake by muscle cells • Decreased protein synthesis • Increased protein breakdown • Muscle wasting and growth retardation

TABLE 26-2 Symptoms of Diabetes Mellitus

Frequent urination (polyuria)
Dehydration, dry mouth
Increased thirst (polydipsia)
Blurred vision
Increased infections
Weight loss
Increased hunger (polyphagia)
Fatigue

and classic symptoms of diabetes (such as polyuria, polydipsia, and unexplained weight loss) are present.

- The plasma glucose concentration is 126 mg/dL or greater after a fast of at least eight hours.
- The plasma glucose concentration measured two hours after a 75-gram glucose load is 200 mg/dL or greater.

Overt symptoms of hyperglycemia help to confirm the diagnosis. Otherwise, a diagnosis of diabetes is confirmed only if a subsequent test yields similar results.

The term **prediabetes** pertains to individuals with blood glucose levels between normal and diabetic, that is, between 100 and 125 mg/dL when fasting (a condition known as *impaired fasting glucose*) or between 140 and 200 mg/dL when measured two hours after ingesting a 75-gram glucose load (a condition known as *impaired glucose tolerance*). Although people with prediabetes are usually asymptomatic, they are at increased risk of developing diabetes and cardiovascular diseases.[3] Prediabetes has been estimated to affect approximately 28 percent of adults in the United States,[4] and it is especially prevalent among those who are overweight or obese.

◆ Reminder: *Osmolarity* refers to the concentration of osmotically active particles in solution. Hyperglycemia causes the body's fluids to become *hyperosmolar,* meaning that they have an abnormally high osmolarity.

◆ Normal fasting plasma glucose levels are approximately 75 to 100 mg/dL (published values vary).

◆ Gestational diabetes was introduced in Chapter 14.

Types of Diabetes Mellitus

Table 26-3 on p. 814 lists features of the two main types of diabetes, type 1 and type 2 diabetes. Pregnancy can lead to abnormal glucose tolerance and the condition known as *gestational diabetes* (discussed later in this chapter), which often resolves after pregnancy but is a risk factor for type 2 diabetes. ◆ Diabetes can also be caused by medical conditions that damage the pancreas or interfere with insulin function.

Type 1 Diabetes **Type 1 diabetes** accounts for about 5 to 10 percent of diabetes cases. It is usually caused by **autoimmune** destruction of the pancreatic beta cells, which produce and secrete insulin. By the time symptoms develop, the damage to the beta cells has progressed so far that insulin must be supplied exogenously, most often by injection. Although the precise cause of the autoimmune attack is usually unknown, environmental toxins or infections are likely triggers. People with type 1 diabetes often have a genetic susceptibility for the disorder and are at increased risk of developing other autoimmune diseases.

renal threshold: the blood concentration of a substance that exceeds the kidneys' capacity for reabsorption, causing the substance to be passed into the urine.

oral glucose tolerance test: a test that evaluates a person's ability to tolerate an oral glucose load.

prediabetes: the condition in which blood glucose levels are higher than normal but not high enough to be diagnosed as diabetes.

type 1 diabetes: the type of diabetes that accounts for 5 to 10 percent of diabetes cases and usually results from autoimmune destruction of pancreatic beta cells.

autoimmune: an immune response directed against the body's own tissues.
- **auto** = self

TABLE 26-3 Features of Type 1 and Type 2 Diabetes

Feature	Type 1	Type 2
Prevalence in diabetic population	5% to 10% of cases	90% to 95% of cases
Age of onset	<30 years	>45 years[a]
Associated conditions	Autoimmune diseases, viral infection, inherited factors	Obesity, aging, inherited factors
Major defect	Destruction of pancreatic beta cells; insulin deficiency	Insulin resistance; insulin deficiency (relative to needs)
Insulin secretion	Little or none	Varies; may be normal, increased, or decreased
Requirement for insulin therapy	Always	Sometimes
Other names	Juvenile-onset diabetes Insulin-dependent diabetes mellitus (IDDM) Ketosis-prone diabetes	Adult-onset diabetes Noninsulin-dependent diabetes mellitus (NIDDM) Ketosis-resistant diabetes

[a] The incidence of type 2 diabetes is increasing in children and adolescents; in over 90% of these cases, it is associated with overweight or obesity and a family history of type 2 diabetes.

◆ Reminder: *Ketone bodies* are products of fat metabolism that are produced in the liver; they accumulate in tissues when fatty acids are released in abnormally high amounts from adipose tissue.

Type 1 diabetes usually develops during childhood or adolescence, and symptoms may appear abruptly in previously healthy children.[5] Classic symptoms are frequent urination, weight loss, and increased thirst. **Ketoacidosis**—acidosis due to excessive production of ketone bodies—is sometimes the first sign of disease. ◆ Disease onset tends to be more gradual in individuals who develop type 1 diabetes in later years. Blood tests that detect antibodies to insulin, pancreatic islet cells, and pancreatic enzymes can confirm the diagnosis and help to predict development of the disease in close relatives.

Type 2 Diabetes **Type 2 diabetes** is the most prevalent form of diabetes, accounting for 90 to 95 percent of cases, and it is often asymptomatic. The primary defect in type 2 diabetes is **insulin resistance,** a reduced sensitivity to insulin in muscle, adipose, and liver cells. To compensate, the pancreas secretes larger amounts of insulin, and plasma insulin concentrations can rise to abnormally high levels **(hyperinsulinemia).** Over time, the pancreas becomes less able to compensate for the cells' reduced sensitivity to insulin, and hyperglycemia worsens. The high demand for insulin can eventually exhaust the beta cells of the pancreas and lead to impaired insulin secretion and reduced plasma insulin concentrations. Type 2 diabetes is therefore associated with both insulin resistance and relative insulin deficiency; that is, the amount of insulin is insufficient to compensate for its diminished effect in the cells.

◆ Highlight 26 provides information about the relationship between obesity and insulin resistance.

Although the actual causes of type 2 diabetes are unknown, the risk is substantially increased by obesity (especially abdominal obesity), aging, and physical inactivity. An estimated 80 to 90 percent of individuals with type 2 diabetes are obese, and obesity itself can directly cause some degree of insulin resistance.[6] ◆ The prevalence of type 2 diabetes increases with age and exceeds 22 percent in persons over 60 years of age; however, many of these cases remain undiagnosed.[7] Inherited factors strongly influence risk, and type 2 diabetes is more common in certain ethnic populations, including Native Americans, Hispanic Americans, Mexican Americans, African Americans, Asian Americans, and Pacific Islanders.

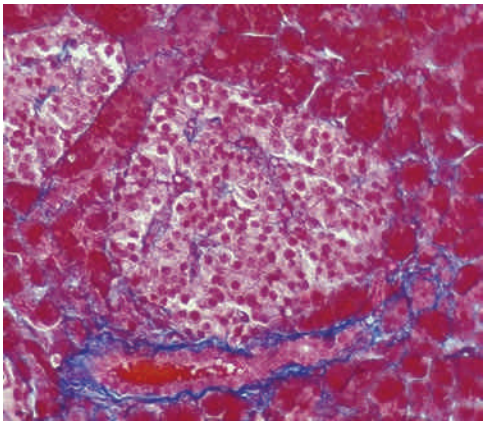
type 2 diabetes: the type of diabetes that accounts for 90 to 95 percent of diabetes cases and usually results from insulin resistance coupled with insufficient insulin secretion.

insulin resistance: reduced sensitivity to insulin in muscle, adipose, and liver cells.

hyperinsulinemia: abnormally high levels of insulin in the blood.

Type 2 Diabetes in Children and Adolescents Although most cases of type 2 diabetes are diagnosed in individuals over 45 years old, children and adolescents who are overweight or have a family history of diabetes also are at increased risk. Because type 2 diabetes is frequently asymptomatic, it is generally detected in children only when high-risk groups are screened for the disease. For example, when 167 obese children of different ethnic groups were screened, prediabetes was detected in 25 percent of children between 4 and 10 years of age and in 21 percent of adolescents between 11 and 18 years of age.[8] Among the Pima Indians in Ari-

zona, a population with one of the highest rates of type 2 diabetes in the world, overt type 2 diabetes was reported in 2.2 percent of 10- to 14-year-old children and in 5 percent of 15- to 19-year-old teens.[9] Routine screening and prevention programs that target food intake and activity patterns can be important safeguards for preventing diabetes in children at risk.



© Carolina Biology Supply/Visuals Unlimited

Cross sections of the pancreas reveal distinct areas known as the islets of Langerhans, which contain the alpha cells that produce glucagon and the beta cells that produce insulin.

Prevention of Type 2 Diabetes Mellitus

Clinical studies suggest that lifestyle changes can delay or prevent the incidence of type 2 diabetes in individuals at risk. In the Diabetes Prevention Program, a multicenter trial of 3234 adults with impaired glucose tolerance, dietary changes and increased physical activity led to a 58 percent reduction in diabetes incidence.[10] Based on the results of this and similar studies, guidelines for diabetes prevention include the following strategies:*[11]

- *Weight management.* A sustained weight loss of 5 to 10 percent of body weight is recommended for overweight and obese individuals. If weight loss cannot be achieved, healthy eating behaviors should be encouraged to prevent additional weight gain.
- *Active lifestyle.* At least 30 minutes of moderate physical activity, such as brisk walking, is recommended daily.
- *Dietary modifications.* An increased intake of whole grains and dietary fiber has been associated with a reduced risk for type 2 diabetes. Individuals who are overweight or obese should decrease their intake of dietary fat to avoid consuming excessive energy.
- *Regular monitoring.* Individuals at risk should be monitored every one or two years to check for the possible development of type 2 diabetes. If necessary, they can be provided with additional counseling, education, or resources.

Clinical trials have found that a light to moderate alcohol intake (one to two drinks per day) may reduce the risk of developing type 2 diabetes, compared with either abstinence from alcohol or heavy drinking. Alcohol's protective effect may be attributable to an increased secretion of adiponectin, an adipose hormone that improves insulin sensitivity.[12] Specific recommendations regarding alcohol intake are unavailable, however, because the risk of adverse effects from alcohol ingestion must be considered on an individual basis.

Acute Complications of Diabetes Mellitus

Untreated diabetes may result in life-threatening complications. As described earlier, insufficient insulin can result in significant disturbances in energy metabolism (review Table 26-1). Severe hyperglycemia can lead to dehydration and electrolyte imbalances. In treated diabetes, hypoglycemia (low blood glucose) is a possible complication of inappropriate management.

Diabetic Ketoacidosis in Type 1 Diabetes A severe lack of insulin causes diabetic ketoacidosis. Without insulin, glucagon's effects become more pronounced, leading to the unrestrained breakdown of the triglycerides in adipose tissue and the protein in muscle. As a result, an increased supply of fatty acids and amino acids arrives in the liver, where fatty acid oxidation and gluconeogenesis proceed unchecked. ◆ The increased rate of fatty acid oxidation results in excessive amounts of acetyl CoA and subsequent ketone body production. Ketone bodies, which are acidic, can reach dangerously high levels in the bloodstream (ketoacidosis) and spill into the urine **(ketonuria).** Blood pH typically falls below 7.30

◆ Chapter 7 provides details about these metabolic pathways.

* The antidiabetic medication metformin may be beneficial for preventing diabetes in high-risk individuals, such as those with obesity, a sedentary lifestyle, prediabetes, and a family history of diabetes.

(blood pH normally ranges between 7.35 and 7.45). In diabetic ketoacidosis, blood glucose concentrations usually exceed 250 mg/dL and may rise above 1000 mg/dL in severe cases. The main features of diabetic ketoacidosis thus include severe ketosis, ◆ acidosis, and hyperglycemia.

◆ Reminder: *Ketosis* is an abnormal increase in the production of ketone bodies.

◆ Bicarbonate is a buffer in the blood that corrects acidosis. The acid (H^+) and bicarbonate (HCO_3^-) combine to form carbonic acid (H_2CO_3), which breaks down to water (H_2O) and carbon dioxide (CO_2). The carbon dioxide is then exhaled.

Patients with ketoacidosis may exhibit symptoms of both acidosis and dehydration. Acidosis is partially corrected by exhalation of carbon dioxide, so rapid or deep breathing is characteristic. ◆ Polyuria and polydipsia (frequent urination and extreme thirst) can accompany the hyperglycemia, lowering blood volume and blood pressure and depleting electrolytes. In response, patients may demonstrate marked fatigue, lethargy, nausea, and vomiting. Ketone accumulation is sometimes evident by a fruity odor on a person's breath **(acetone breath).** Mental state may vary from alertness to comatose **(diabetic coma).** Diabetic coma was a frequent cause of death before insulin was routinely used to manage diabetes.

Diabetic ketoacidosis is sometimes the earliest sign that leads to diagnosis of type 1 diabetes, but more often it results from inappropriate treatment (such as missed insulin injections), illness or infection, alcohol abuse, or other physiological stressors.[13] The condition usually develops quickly, within hours or a few days. It is a medical emergency that requires insulin therapy to correct the hyperglycemia, intravenous fluid and electrolyte replacement, and in some cases, bicarbonate therapy to treat acidosis. Antibiotics may be necessary if infection is present. The mortality rate in diabetic ketoacidosis is nearly 5 percent in individuals under 40 years of age, but exceeds 20 percent in elderly individuals.[14]

Hyperosmolar Hyperglycemic State in Type 2 Diabetes The **hyperosmolar hyperglycemic state** is a condition of severe hyperglycemia, dehydration, and hyperosmolarity that develops in the absence of significant ketosis. When ketosis is present, it is much milder than in diabetic ketoacidosis because enough insulin is available in type 2 diabetes to suppress fatty acid oxidation and consequent ketone body production. Because glucagon's actions dominate, however, gluconeogenesis leads to dramatic increases in blood glucose levels, which typically exceed 600 mg/dL and may rise above 2000 mg/dL. The extreme hyperglycemia causes substantial fluid losses, leading to depleted blood volume and electrolyte imbalances. Blood plasma may become so hyperosmolar as to cause neurological abnormalities, such as abnormal reflexes, motor impairments, reduced verbal ability, and seizures; about 10 percent of patients lapse into coma.

The hyperosmolar hyperglycemic state is sometimes the first sign of type 2 diabetes in older persons. It is usually precipitated by infection, illness, or a drug treatment that impairs insulin action or secretion, and it often develops because patients are unable to recognize thirst or adequately replace fluid losses due to age, illness, sedation, or incapacity. Unlike diabetic ketoacidosis, the condition often evolves slowly, over several days or weeks; the absence of clinical signs can delay its diagnosis. Treatment includes intravenous fluid and electrolyte replacement and insulin therapy. The mortality rate approaches 15 percent, primarily because the condition occurs more often in older patients who have cardiovascular disease or other major illnesses.[15]

Hypoglycemia **Hypoglycemia,** or low blood glucose, is the most frequent complication of type 1 diabetes and may occur in type 2 diabetes as well. It arises from the inappropriate management of diabetes rather than from the disease itself, and it usually results from excessive dosages of insulin or antidiabetic drugs, prolonged exercise, skipped or delayed meals, inadequate food intake, or the consumption of alcohol without food. Symptoms of hypoglycemia include sweating, shakiness, heart palpitations, slurred speech, double vision, and irritability. Mental confusion may prevent a person from recognizing the problem and taking such corrective action as ingesting glucose tablets, juice, or candy. If hypoglycemia occurs during the night, patients may be completely unaware of its presence. Severe hypoglycemia or a delay in treatment can cause irreversible brain

damage. Hypoglycemia is the most frequent cause of coma in insulin-treated patients and is believed to account for 3 to 4 percent of deaths in this population.[16]

Chronic Complications of Diabetes Mellitus

Excessive blood glucose can eventually alter cellular functions and damage cells and tissues. Glucose nonenzymatically combines with proteins, producing molecules that ultimately break down to form reactive compounds known as **advanced glycation end products (AGEs);** these AGEs can accumulate and cause damage to cells and blood vessels. Excessive glucose also promotes the production and accumulation of sorbitol, which increases oxidative stress and alters molecular structures and functions. The chronic complications of diabetes typically involve the large blood vessels **(macrovascular complications),** smaller vessels such as arterioles and capillaries **(microvascular complications),** and the nervous system **(diabetic neuropathy).** Other tissues adversely affected by diabetes include the lens of the eye and the skin; cataracts, glaucoma, and various skin disorders sometimes develop. Increased infections are common in diabetes, a possible consequence of hyperglycemia, impaired circulation, or depressed immune responses. In individuals with type 2 diabetes, complications often develop before the diabetes is diagnosed.

Macrovascular Complications The damage caused by diabetes accelerates the development of atherosclerosis in the coronary arteries and the arteries of the limbs. Cardiovascular diseases are the leading cause of death in people with diabetes, accounting for up to 70 percent of deaths.[17] Type 2 diabetes is often accompanied by multiple risk factors for coronary heart disease, including hypertension, abnormal blood lipids, and obesity. ◆ In addition, people with diabetes have increased tendencies for thrombosis (blood clot formation) and abnormal ventricle function, both of which can worsen the clinical course of heart disease.[18]

◆ People with type 2 diabetes frequently develop the *metabolic syndrome*, a cluster of symptoms associated with insulin resistance (including hyperglycemia, hypertension, and altered blood lipids) that substantially increase heart disease risk (see Highlight 26).

Impaired blood flow in the arteries of the limbs increases the risk of **claudication** (pain while walking) and contributes to the development of foot ulcers (see the photo). Left untreated, foot ulcers can lead to **gangrene** (tissue death), and some patients require foot amputation, a major cause of disability in individuals with diabetes. About 15 to 20 percent of persons with diabetes are hospitalized with foot complications during the course of illness.[19]

© SPL/Photo Researchers, Inc.

Foot ulcers are a common complication of diabetes because blood circulation is impaired (which slows healing) and nerve damage dampens foot pain (delaying recognition and treatment of cuts and bruises).

Microvascular Complications Long-term diabetes is associated with a thickening of the basement membrane of capillaries and small arterioles, which impairs the normal functioning of these blood vessels. The primary microvascular complications involve the retina of the eye and the kidneys. Diabetes is currently the leading cause of both adult blindness and kidney failure in the United States.[20]

In **diabetic retinopathy,** the weakened capillaries of the retina leak fluid, lipids, or blood, causing local edema or hemorrhaging. The defective blood flow also leads to damage and scarring within retinal tissue. New blood vessels eventually form, but they are fragile and bleed easily, releasing blood and proteins that obscure vision. The retinal changes usually occur after an individual has had diabetes for many years; for example, 80 percent of diabetes patients develop retinopathy after 15 years.[21] Diabetic retinopathy progresses most rapidly when diabetes is poorly controlled, and intensive management substantially reduces the risk.

In **diabetic nephropathy,** damage to the kidneys' specialized capillaries prevents adequate filtration of the blood, which is evidenced by abnormal protein losses in the urine **(microalbuminuria).** As the kidney damage worsens, urine production decreases and nitrogenous wastes accumulate in the blood; eventually, the individual requires dialysis (artificial filtration of blood) to survive. ◆ Because the kidneys normally regulate blood volume and blood pressure (see pp. 401–402), inadequate kidney function leads to high blood pressure in patients with nephropathy. Kidney failure eventually develops in about 30 to 35 percent of

◆ Chapter 28 provides details about the progression and treatment of chronic kidney disease.

advanced glycation end products (AGEs): reactive compounds formed after glucose combines with protein; AGEs can damage tissues and lead to diabetic complications.

patients with type 1 diabetes and 20 percent of those with type 2 diabetes.[22] As with diabetic retinopathy, intensive diabetes management can help slow the progression of kidney damage.

Diabetic Neuropathy Neuropathy, or nerve degeneration, occurs in about 50 percent of diabetes cases.[23] The extent of nerve damage depends on the severity and duration of hyperglycemia. Symptoms of neuropathy vary and may be experienced as pain or burning, numbness and tingling in the hands and feet, or loss of sensation. Pain and cramping, especially in the legs, are often severe during the night and may interrupt sleep. Neuropathy also contributes to the development of foot ulcers because cuts and bruises may go unnoticed until wounds are severe. Other manifestations of neuropathy include sweating abnormalities, sexual dysfunction, constipation, and delayed stomach emptying **(gastroparesis).**

IN SUMMARY

Diabetes mellitus is a chronic condition characterized by inadequate insulin secretion or impaired insulin action. In type 1 diabetes, the pancreas secretes little or no insulin, and insulin therapy is necessary for survival. Type 2 diabetes is characterized by insulin resistance coupled with relative insulin deficiency, and disease risk is increased by obesity, aging, and physical inactivity. Acute complications of diabetes include diabetic ketoacidosis, in which hyperglycemia is accompanied by ketosis and acidosis, and the hyperosmolar hyperglycemic state, characterized by severe hyperglycemia, dehydration, and possible mental impairments. Another acute complication, hypoglycemia, is usually a consequence of inappropriate disease management. Chronic complications of diabetes include macrovascular disorders such as cardiovascular diseases and peripheral vascular disease, microvascular conditions such as diabetic retinopathy and diabetic nephropathy, and diabetic neuropathy.

Treatment of Diabetes Mellitus

Diabetes is a chronic and progressive illness that requires lifelong treatment. Managing blood glucose levels is a delicate balancing act that involves meal planning, proper timing of medications, and physical exercise. Frequent adjustments in treatment are often necessary to establish good **glycemic** control. Individuals with type 1 diabetes require insulin therapy for survival. Type 2 diabetes is initially treated with diet therapy and exercise, but most patients eventually need antidiabetic medications or insulin. Diabetes management becomes even more difficult once complications develop. Although the health care team must determine the appropriate therapy, the individual with diabetes ultimately assumes much of the responsibility for treatment and therefore requires education in self-management of the disease.

Treatment Goals

The main goal of diabetes treatment is to maintain blood glucose levels within a desirable range to prevent or reduce the risk of complications. As discussed in the next section, clinical trials have demonstrated that *intensive* diabetes treatment, which keeps blood glucose levels tightly controlled, can reduce the incidence and severity of chronic complications. Therefore, maintenance of near-normal glucose levels has become the fundamental objective of all diabetes care plans. Other goals of treatment include maintaining healthy blood lipid concentrations, controlling blood pressure, and managing weight—measures that can help to prevent or delay diabetes complications as well.

glycemic (gly-SEE-mic): pertaining to blood glucose.

TABLE 26-4 Comparison of Conventional and Intensive Therapies for Type 1 Diabetes

	Conventional Therapy	Intensive Therapy
Blood glucose monitoring	Monitored daily	Monitored at least three times daily
Insulin therapy	One or two daily injections; no daily adjustments	Three or more daily injections or use of external insulin pump; dosage adjusted according to results of glucose monitoring and expected carbohydrate intake
Advantages	Fewer incidences of severe hypoglycemia; less weight gain	Delayed progression of retinopathy, nephropathy, and neuropathy
Disadvantages	More rapid progression of retinopathy, nephropathy, and neuropathy	Twofold to threefold increase in severe hypoglycemia; weight gain; increased risk of becoming overweight

Benefits of Intensive Treatment Several landmark studies conducted in the 1980s and 1990s confirmed that keeping blood glucose levels as close to normal as possible offers clear advantages over less rigorous diabetes treatment. The Diabetes Control and Complications Trial was a multicenter trial that tested whether the intensive treatment of type 1 diabetes would decrease the frequency and severity of microvascular and neurological complications.[24] In this study, 1441 persons with type 1 diabetes were randomly assigned to receive either conventional or intensive therapy, as summarized in Table 26-4. The subjects were followed for an average of 6.5 years. The participants undergoing intensive therapy had delayed onset and reduced progression of retinopathy, nephropathy, and neuropathy; however, they also experienced increased incidences of severe hypoglycemia and gained more weight. A later trial, the United Kingdom Prospective Diabetes Study, found similar advantages to using intensive treatment in type 2 diabetes.*[25]

Diabetes Self-Management Education Newly diagnosed patients and their families have much to learn about diabetes and its management. Diabetes education provides an individual with the knowledge and skills necessary to implement treatment. The primary instructor is often a **Certified Diabetes Educator (CDE)**, a health care professional (often a nurse or dietitian) who has specialized knowledge about diabetes treatment and the health education process. To manage diabetes, patients need to learn about appropriate meal planning, medication administration, blood glucose monitoring, weight management, appropriate physical activity, and prevention of complications.

Evaluating Diabetes Treatment

Diabetes treatment is largely evaluated by monitoring glycemic status. Good glycemic control requires frequent home monitoring of blood glucose using a glucose meter, referred to as **self-monitoring of blood glucose.** In this procedure, a drop of blood from a finger prick is applied to a chemically treated paper strip, which is then analyzed for glucose. Glucose testing provides valuable feedback when the patient adjusts food intake, medications, and physical activity and is helpful for preventing hypoglycemia. Ideally, patients with type 1 diabetes should monitor blood glucose three or more times daily—and more frequently when therapy is adjusted. Self-monitoring of blood glucose is also useful in type 2 diabetes, although the recommended frequency depends on the specific needs of individual patients.[26]

Long-Term Glycemic Control Health care providers periodically evaluate long-term glycemic control by measuring **glycated hemoglobin** (abbreviated **HbA_{1c}**). The glucose in blood freely enters red blood cells and nonenzymatically attaches to hemoglobin molecules in direct proportion to the amount of glucose

Certified Diabetes Educator (CDE): a health care professional who specializes in diabetes management education. Certification is obtained from the National Certification Board for Diabetes Educators.

self-monitoring of blood glucose: home monitoring of blood glucose levels using a glucose meter.

glycated hemoglobin (HbA_{1c}): hemoglobin molecules to which glucose has been nonenzymatically attached; the level of HbA_{1c} in blood helps to evaluate long-term glycemic control. Also called *glycosylated hemoglobin.*

*Intensive treatment may be inappropriate for some individuals with diabetes; examples include individuals with limited life expectancies or a history of hypoglycemia and middle-aged or older adults with previous heart disease or multiple heart disease risk factors.

© Tony Freeman/PhotoEdit

Self-monitoring of blood glucose can help individuals with diabetes learn how to maintain blood glucose levels within a desirable range.

present. Because the life span of red blood cells averages 120 days, the percentage of HbA_{1c} is a measure of glycemic control during the preceding two to three months (the average age of circulating red blood cells).[27] In people without diabetes, HbA_{1c} is typically less than 6 percent of total hemoglobin. The goal of diabetes treatment is an HbA_{1c} value under 7 percent,[28] but the concentration is often markedly higher even in people with diabetes who are maintaining near-normal blood glucose levels.

The **fructosamine test** is sometimes conducted to determine glycemic control for the preceding two-week period. This test determines the nonenzymatic glycation of serum proteins (primarily albumin), which have a shorter half-life than hemoglobin. Most often, the fructosamine test is used to evaluate recent adjustments in diabetes treatment or glycemic control during pregnancy. The test cannot be interpreted correctly in patients with kidney or liver disease.

Monitoring for Long-Term Complications Individuals with diabetes are routinely monitored for signs of long-term complications. Blood pressure is measured at each checkup. Annual lipid screening is suggested for most adult patients. Routine checks for urinary protein (microalbuminuria) help to determine if nephropathy has developed. Physical examinations generally screen for signs of retinopathy, neuropathy, and foot problems.

Ketone Testing Ketone testing checks for the development of ketoacidosis if symptoms are present or if risk has increased due to acute illness, stress, or pregnancy. Both blood and urine tests are available for home use, although the blood tests are currently more reliable.[29] Ketone testing is most useful for patients who have type 1 diabetes or gestational diabetes. Individuals with type 2 diabetes may produce excessive ketone bodies when severely stressed by infection or trauma.

Body Weight Concerns

Whereas individuals with newly diagnosed type 1 diabetes are likely to be thin, most people with type 2 diabetes are overweight or obese. Body weight and children's growth patterns are monitored to evaluate whether energy intakes are appropriate.

Body Weight in Type 1 Diabetes In general, people with type 1 diabetes are less likely to be overweight than those in the general population. However, excessive weight gain is sometimes an unwanted side effect of improved glycemic control, especially in those undergoing intensive insulin therapy. Although the cause of weight gain is unclear, it is possibly related to the insulin treatment, which may stimulate fat synthesis or induce energy intake in some way.[30] In addition, insulin treatment eliminates energy losses from glycosuria, a change that can contribute to energy excess.[31] Although patients should try to prevent excessive weight gain, concerns about weight should not discourage the use of intensive therapy, which is associated with longer life expectancy and fewer complications than occur with conventional therapy. It is also important to ensure that growing children receive sufficient energy for normal growth and development.

Body Weight in Type 2 Diabetes Because excessive body fat can worsen insulin resistance, weight loss is often recommended for those who are overweight or obese. Even moderate weight loss (10 to 20 pounds) can help to improve glycemic control, blood lipid levels, and blood pressure. Weight loss is most beneficial early in the course of diabetes, before insulin secretion has diminished. The positive effects appear to be related to kcaloric restriction rather than to weight loss itself, and improvements in blood glucose usually appear within days after a weight-loss program is initiated.[32] Clinical studies, however, have indicated that the improved glycemic control often diminishes within a year after weight loss. The reason for this outcome may be that subjects are no longer restricting kcalories and have begun to regain the lost weight.[33]

fructosamine test: a measurement of glycated serum proteins; used to analyze glycemic control over the preceding two weeks. Also known as the *glycated albumin test* or the *glycated serum protein test.*

Not all persons with type 2 diabetes are overweight or obese. Older adults and those in long-term care facilities are often underweight and may need to gain weight. Low body weight increases risks of morbidity and mortality in these individuals.

Medical Nutrition Therapy: Nutrient Recommendations

Medical nutrition therapy has a considerable influence on diabetes outcome. The appropriate dietary choices can both improve blood glucose levels and slow the progression of diabetes complications. As always, the nutrition care plan must take personal preferences and lifestyle habits into account. Dietary intakes need to be modified to accommodate growth, lifestyle changes, aging, and any complications that develop. Although all members of the diabetes care team should understand the principles of dietary treatment, a registered dietitian is best suited to design and implement the medical nutrition therapy for diabetes patients. This section presents the nutrient recommendations for diabetes. Meal-planning strategies are described later in the chapter.

Total Carbohydrate Intake The amount of carbohydrate ingested has the greatest influence on blood glucose levels after meals—the more grams of carbohydrate ingested, the greater the glycemic response. The carbohydrate recommendation is based in part on the person's metabolic needs (that is, the type of diabetes or degree of glucose tolerance) and individual preferences. In addition, the carbohydrate intake must be fairly consistent at meals and snacks to help reduce fluctuations in blood glucose levels between meals. Low-carbohydrate diets, which restrict carbohydrate intake to less than 130 grams per day, are not recommended.[34]

Carbohydrate Sources Different carbohydrate-containing foods have different effects on blood glucose levels; for example, consuming a portion of white rice may cause blood glucose to rise more than would consuming a similar portion of barley. This *glycemic effect* of foods is influenced by the type of carbohydrate in a food, the food's fiber content, the preparation method, the other foods included in a meal, and individual tolerances. The glycemic index (GI), a ranking of carbohydrate foods based on their average glycemic effect, has been compiled from the scientific literature; some individuals may find this resource helpful when making food choices. ◆ The GI is not a primary consideration when treating diabetes, however, because research studies investigating the possible benefits of low-GI diets on glycemic control have had mixed results.[35] In addition, there is considerable variability in individual responses to specific carbohydrate foods. Nonetheless, high-fiber, minimally processed foods, which typically have more moderate effects on blood glucose than do highly processed, starchy foods, are among the foods frequently recommended for persons with diabetes.

◆ Chapter 4 provides additional information about the glycemic index (see pp. 115–116). The website **www.glycemicindex.com** provides glycemic index values for a wide variety of common foods.

Fiber Fiber recommendations for individuals with diabetes are similar to those for the general population; ◆ thus, people with diabetes are encouraged to include fiber-rich foods such as legumes, whole-grain cereals, fruits, and vegetables in their diet. Although some studies have suggested that very high intakes of fiber (50 grams or more per day) may improve glycemic control, the benefits have not been consistent across studies, and many individuals may have difficulty tolerating such large amounts of fiber.[36]

◆ The fiber DRI for adult women and men ranges from 21 to 38 g; check the DRI table on the inside front cover of this text for specific values.

Sugars A common misperception is that people with diabetes need to avoid sugar and sugar-containing foods. In reality, table sugar (sucrose), made up of glucose and fructose, has a lower glycemic effect than that of starch. Because moderate consumption of sugar has not been shown to adversely affect glycemic control,[37] sugar recommendations for people with diabetes are similar to those for the general population, which suggest minimizing foods and beverages that contain

added sugars. However, sugars and sugary foods must be counted as part of the daily carbohydrate allowance.

Although fructose has a minimal glycemic effect, its use as an added sweetener is not advised because excessive dietary fructose may adversely affect blood lipid levels. (Note that it is not necessary to avoid the naturally occurring fructose in fruits and vegetables.) Sugar alcohols (such as sorbitol and maltitol) have lower glycemic effects than glucose, fructose, or sucrose, but their use has not been found to significantly improve long-term glycemic control. Artificial sweeteners (such as aspartame, saccharin, and sucralose) contain no digestible carbohydrate and can be safely used in place of sugar.

Dietary Fat As mentioned earlier, people with diabetes are at high risk of developing cardiovascular diseases. Guidelines for dietary fat are similar to those for other persons at risk: saturated fat intake should be limited to less than 7 percent of total kcalories, *trans* fat intake should be minimized, and cholesterol intake should be limited to less than 200 milligrams daily.[38] Dietary strategies for cardiovascular disease are discussed further in Chapter 27.

Protein The protein intake in people with diabetes should be between 15 and 20 percent of total kcalories, which is the usual range of protein intake in the general population. Although small, short-term studies have suggested that diets with higher protein intakes may improve glycemic control, increase satiety, and help with weight loss, the long-term effects of such diets on diabetes management and complications are unknown.[39] In addition, high protein intakes are discouraged because they may be detrimental to kidney function in some individuals.

Alcohol Use in Diabetes Alcohol can be used in moderation by adults with diabetes. Guidelines are similar to those for the general population, which advise a daily limit of one drink for women and two drinks for men. ◆ However, individuals using insulin or medications that promote insulin secretion should consume food when they ingest alcoholic beverages to avoid hypoglycemia. Alcohol can cause hypoglycemia by interfering with glucose production in the liver. Conversely, excessive alcohol can worsen hyperglycemia, and it can also raise triglyceride levels in susceptible persons. People who should avoid alcohol include pregnant women and individuals with pancreatitis, advanced neuropathy, abnormally high triglyceride levels, or a history of alcohol abuse.[40]

◆ Reminder: One drink is equivalent to 12 ounces of beer; 5 ounces of wine; 10 ounces of wine cooler; or $1^1/_2$ ounces of 80 proof distilled spirits such as gin, rum, vodka, and whiskey.

Micronutrients Micronutrient recommendations for people with diabetes are the same as for the general population. Vitamin and mineral supplementation is not recommended unless nutrient deficiencies develop; those at risk include the elderly, pregnant or lactating women, strict vegetarians, and individuals on kcalorie-restricted diets.[41] Although some studies have suggested that supplemental chromium can improve glycemic control in type 2 diabetes, results have not been consistent. At present, chromium supplementation is not recommended for those with type 2 diabetes.

Medical Nutrition Therapy: Meal-Planning Strategies

Dietitians provide a number of meal-planning strategies to help people with diabetes maintain glycemic control. These strategies emphasize control of carbohydrate intake and portion sizes. A regular eating pattern, with carbohydrate intake spaced evenly throughout the day, is typically recommended. Sample menus, which include commonly eaten foods, can help to illustrate general principles. Initial dietary instructions may include a discussion of the *Dietary Guidelines for Americans* or other recommendations designed for the general population (see Chapter 2), as well as guidelines for improving blood lipids and other cardiovascular risk factors. People using intensive insulin therapy must learn to coordinate

insulin injections with meals and to match insulin dosages to carbohydrate intake, as discussed later.

Carbohydrate Counting Carbohydrate-counting techniques are simpler and more flexible than other menu-planning approaches and are widely used for planning diabetes diets. Carbohydrate counting works as follows: After a dietitian determines a person's nutrient and energy needs, the individual is given a daily carbohydrate allowance, often divided into a pattern of meals and snacks according to individual preferences. The carbohydrate allowance can be expressed in grams or as the number of carbohydrate portions allowed per meal (see Table 26-5 on p. 824). The user of the plan need only be concerned about meeting carbohydrate goals and can select from any of the carbohydrate-containing food groups when planning meals (see Table 26-6 on p. 824 and Figure 26-2 on p. 825). Although encouraged to make healthy food choices, the individual has the freedom to choose the foods desired at each meal without risking loss of glycemic control. Some people may also need guidance about noncarbohydrate foods to help them choose a healthy diet that improves blood lipids or energy intakes. The "How to" on pp. 824–825 provides more information about using carbohydrate counting in clinical practice.

Carbohydrate counting is taught at different levels of complexity depending on a person's needs and abilities. The basic carbohydrate-counting method just described can be helpful for most people, although it requires a consistent carbohydrate intake from day to day to match the medication or insulin regimen. Advanced carbohydrate counting allows more flexibility but is best suited for patients using intensive insulin therapy. With this method, a person can determine the specific dose of insulin needed to cover the amount of carbohydrate consumed at a meal. The person is then free to choose the types and portions of food desired without sacrificing glycemic control. Advanced carbohydrate counting requires some training and should be attempted only after an individual has mastered more basic methods.

Exchange Lists for Meal Planning The exchange list system is an alternative meal-planning method, although it is more complex and difficult for patients to learn than carbohydrate counting. This system of meal planning was introduced in Chapter 2 and is described further in Appendix G (Appendix I for Canadians). The exchange system sorts foods according to their proportions of carbohydrate, fat, and protein so that each item in a food group (or "exchange list") has a similar macronutrient and energy content (see pp. G-1–G-2). Thus any food on a list can be exchanged, or traded, for any other food on the same list without affecting the macronutrient balance in a day's meals. Although the exchange list system can be helpful for individuals who want a structured dietary plan that provides specific percentages of protein, carbohydrate, and fat, it offers no advantages for maintaining glycemic control and is less flexible than carbohydrate counting.

The exchange lists can be helpful resources for individuals using carbohydrate-counting methods because the portions in the exchange lists are interchangeable with the portions used in carbohydrate counting. For example, foods listed in the starch, fruit, and milk exchange lists are equivalent to carbohydrate "portions," as each item contains approximately 15 grams of carbohydrate (see Tables G-4, G-5, and G-6; note that the carbohydrate in the milk exchanges can be rounded up to 15 grams). In the list labeled "Sweets, Desserts, and Other Carbohydrates" (Table G-7), the number of carbohydrate portions per serving is indicated in the far-right column.

Insulin Therapy

Insulin therapy is necessary for individuals who cannot produce enough insulin to meet their metabolic needs. It is therefore required by people with type 1 diabetes and those with type 2 diabetes who cannot maintain glycemic control with antidiabetic medications, diet, and exercise. The pancreas normally secretes insulin in rel-

HOW TO Use Carbohydrate Counting in Clinical Practice

1. The first step in basic carbohydrate counting is to determine an appropriate carbohydrate intake and suitable distribution pattern; an example is shown in Table 26-5. A nutrition assessment can help to estimate a person's usual energy and carbohydrate intakes. The carbohydrate level should be acceptable to the person using the plan. Frequent monitoring of blood glucose levels can help determine whether additional carbohydrate restriction would be helpful.

   The example given in Table 26-5 illustrates a meal pattern for a person consuming 2000 kcalories daily with a carbohydrate allowance of 50 percent of kcalories. This is calculated as follows:

   $$50\% \times 2000 \text{ kcal} = 1000 \text{ kcal of carbohydrate}$$

   $$\frac{1000 \text{ kcal carbohydrate}}{4 \text{ kcal/g carbohydrate}} = 250 \text{ g carbohydrate/day}$$

   $$\frac{250 \text{ g carbohydrate}}{15 \text{ g/1 carbohydrate portion}} = 16.7 \text{ carbohydrate portions/day}$$

2. The distribution of carbohydrates among meals and snacks is based on both individual preferences and metabolic needs. In type 1 diabetes, the insulin regimen must coordinate with the individual's dietary and lifestyle choices. People using conventional insulin therapy must have a consistent carbohydrate intake from day to day to match their particular insulin prescription, whereas those using intensive therapy can alter insulin dosages when carbohydrate intakes change. People with type 2 diabetes are encouraged to develop dietary patterns that suit their lifestyle and medication schedules. For all types of diabetes, the carbohydrate recommendation may need to be altered periodically to improve blood glucose control.

3. Carbohydrate counting can be done in one of two ways:
   - Count the grams of carbohydrate provided by foods.
   - Count carbohydrate portions, expressed in terms of servings that contain approximately 15 grams each.

   Success with carbohydrate counting requires knowledge about the food sources of carbohydrates and an understanding of portion control. As shown in Table 26-6, food selections that contain about 15 grams of carbohydrate are interchangeable. The portions of foods that contain 15 grams may vary substantially, however, even among foods in a single food group. Accurate carbohydrate counting often requires instruction and practice in portion control using measuring cups, spoons, and a food scale. Food lists that indicate the carbohydrate contents of common foods are available from the American Diabetes Association and the American Dietetic Association; these are helpful resources for learning carbohydrate-counting methods.

   When using packaged foods, individuals should check the Nutrition Facts panel of food labels to find the carbohydrate content of a serving. If the fiber content is greater than 5 grams per serving, it should be subtracted from the *Total Carbohydrate* value, as fiber does not contribute to blood glucose. If the sugar alcohol content is greater than 5 grams per serving, half of the grams of sugar alcohol can be subtracted from the *Total Carbohydrate* value.

TABLE 26-5 Sample Carbohydrate Distribution for a 2000-kCalorie Diet

	Carbohydrate Allowance	
Meals	**Grams**	**Portions[a]**
Breakfast	60	4
Lunch	60	4
Afternoon snack	30	2
Dinner	75	5
Evening snack	30	2
Totals	**255 g**	**17**

NOTE: The carbohydrate allowance in this example is approximately 50% of total kcalories.
[a]1 portion = 15 g carbohydrate = 1 portion of starchy food, milk, or fruit.

TABLE 26-6 Portion Sizes of Carbohydrate-Containing Foods

Food Groups with Sample Portion Sizes

Bread, cereal, rice, and pasta: 1 portion = 15 g carbohydrate.
1 slice of bread or 1 tortilla
1/2 English muffin
3/4 c unsweetened, ready-to-eat cereal
1/2 c cooked oatmeal
1/3 c cooked rice or pasta

Fruit: 1 portion = 15 g carbohydrate.
1 medium apple, orange, or peach
1 small banana
3/4 c blueberries or chopped pineapple
1/2 c apple juice or orange juice

Milk products: 1 portion = 12 g carbohydrate; may be rounded up to 15 g for ease in counting carbohydrate portions.
1 c milk (whole, low-fat, or fat-free)
1 c buttermilk
6 oz plain yogurt

Starchy vegetables: 1 portion = 15 g carbohydrate.
1 small (3-oz) potato
1/2 c canned or frozen corn
1/3 c baked beans
1 c winter squash, cubed

Sweets and desserts: Considerable variation in carbohydrate content; portions listed contain approximately 15 g.
1/2 c ice cream
2 sandwich cookies (with cream filling)
1/2 frosted cupcake
1 granola bar (1 oz)
1 tbs honey

Nonstarchy vegetables: 1 portion = 3 to 6 g carbohydrate; 3 servings are equivalent to 1 carbohydrate portion; can be disregarded if less than 3 servings are consumed.
1/2 c cooked cauliflower
1/2 c cooked cabbage, collards, or kale
1/2 c cooked okra
1/2 c diced or raw tomatoes

NOTE: Unprocessed meats, fish, and poultry contain negligible amounts of carbohydrate.

HOW TO Use Carbohydrate Counting in Clinical Practice—*continued*

4. Once they have learned the basic carbohydrate-counting method, individuals can select whatever foods they wish, as long as they do not exceed their carbohydrate goals. Figure 26-2 shows a day's menu that follows the dietary plan shown in Table 26-5. Although carbohydrate counting focuses on a single macronutrient, people using this technique should be encouraged to follow a healthy eating plan that meets other dietary objectives as well.

FIGURE 26-2 Translating Carbohydrate Portions into a Day's Meals

SAMPLE MENU

	Carbohydrate Portions
Breakfast:	
Carbohydrate goal = 4 portions or 60 g.	
3/4 c unsweetened, ready-to-eat cereal	1
1/2 c low-fat milk	1/2
1 scrambled egg	—
1 slice whole wheat toast (with margarine or butter)	1
6 oz orange juice	1 1/2
Coffee (without milk or sugar)	—
Lunch:	
Carbohydrate goal = 4 portions or 60 g.	
1 tuna salad sandwich (includes 2 slices whole-grain bread, mayonnaise)	2
6 oz yogurt (plain) with 3/4 c blueberries and artificial sweetener	2
Diet cola	—
Afternoon snack:	
Carbohydrate goal = 2 portions or 30 g.	
2 sandwich cookies	1
1 c low-fat millk	1
Dinner:	
Carbohydrate goal = 5 portions or 75 g.	
4 oz grilled steak	—
1 small baked potato (with margarine or butter)	1
Corn on cob, 1 large ear	2
1/2 c steamed collard greens[a] 1 c sliced, raw tomatoes[a]	1
1/2 c ice cream	1
Evening snack:	
Carbohydrate goal = 2 portions or 30 g.	
1 medium apple	1
1 oz granola bar	1

[a]Three servings of nonstarchy vegetables are equivalent to 1 carbohydrate portion.

atively low amounts between meals and during the night (called *basal insulin*) and in much higher amounts when meals are ingested. Ideally, the insulin treatment should reproduce the natural pattern of insulin secretion as closely as possible.

Insulin Preparations The forms of insulin that are available differ by their onset of activity, timing of peak activity, and duration of effects. Figure 26-3 on p. 826 and Table 26-7 show how insulin preparations are classified: they may be rapid acting (lispro, aspart, and glulisine), short acting (regular), intermediate acting (NPH), or long acting (glargine and detemir), thereby allowing substantial flexibility in establishing a suitable insulin regimen.[42] The rapid- and short-acting insulins are used at mealtimes, whereas the intermediate- and long-acting insulins provide basal insulin for the periods between meals and during the night. Thus, mixtures of several types of insulin can produce greater glycemic control than any one type alone. Several premixed formulations are also available; several examples are listed in Table 26-7.

Most insulin is produced by recombinant DNA techniques that allow the mass production of human insulin by bacteria or yeast. The different forms of insulin are made by chemically modifying insulin's amino acid sequence or by combining insulin with special buffers or peptides that alter insulin's concentration, solubility, or duration of activity in the body.

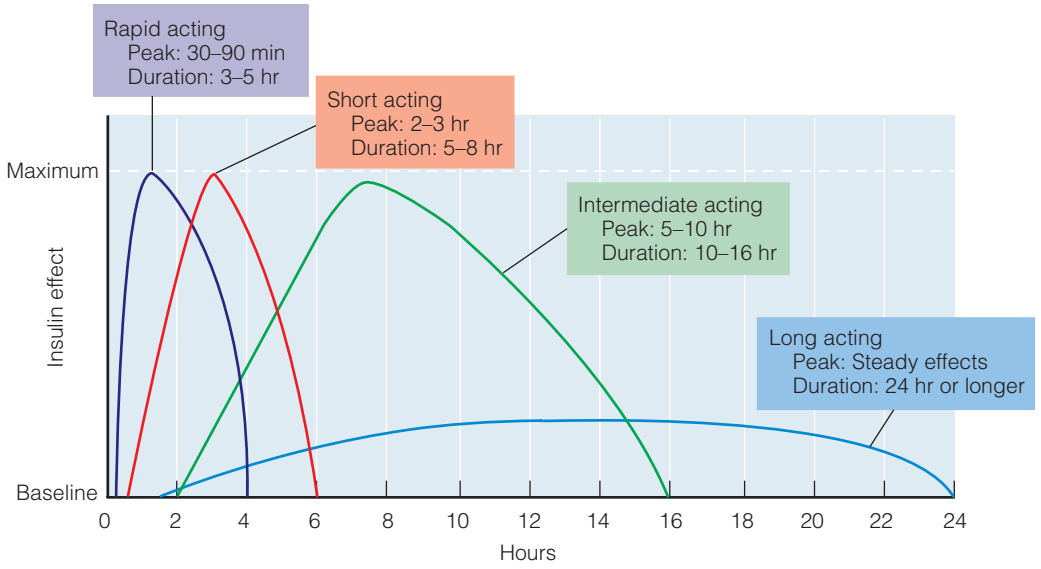
Insulin Delivery Insulin is most often administered by **subcutaneous** injection, either self-administered or provided by caregivers. ◆ Disposable **syringes,** which can be filled from vials that contain multiple doses of insulin, are the most common devices used for injecting insulin. Another option is to use insulin pens,

◆ Because insulin is a protein, it would be destroyed by digestive processes if taken orally.

subcutaneous (sub-cue-TAY-nee-us): beneath the skin.

syringes: devices used for injecting medications. A syringe consists of a hypodermic needle attached to a hollow tube with a plunger inside.

FIGURE 26-3 Effects of Insulin Preparations



© Spencer Grant/Photo Researchers, Inc.

External insulin pumps deliver insulin continuously through thin, flexible tubing inserted into the skin.

which look like permanent marking pens; these injection devices eliminate the need to carry syringes and separate containers of insulin. Insulin pens are available as disposable pens, which contain prefilled insulin, and reusable pens, which can be fitted with prefilled cartridges and replaceable needles. To eliminate the need for multiple punctures, injection ports for insulin are sometimes inserted through the skin and left in place for several days. Another option is an insulin pump, a computerized device that can be programmed to deliver basal insulin continuously and bolus doses at mealtimes. The pump infuses insulin through thin, flexible tubing that remains in the skin. The pump can be worn under clothes, attached to a belt, or kept in a pocket.

An inhalation powder that supplied rapid-acting insulin was available for several years but is no longer marketed due to inadequate sales. Alternative forms of insulin that can be inhaled are currently under development.

Insulin Regimen for Type 1 Diabetes Type 1 diabetes is best managed with intensive insulin therapy, which involves multiple daily injections of several types of insulin or the use of an insulin pump (review Table 26-4). Usually, intermediate- or long-acting insulin meets basal insulin needs, and rapid- or short-acting insulin is injected before meals. ◆ Three or more daily injections are required for good glycemic control. Simpler regimens involve twice-daily injections of a mixture of intermediate- and short-acting insulin. Regimens that include three or more injections allow for greater flexibility in carbohydrate intake and meal tim-

◆ Rapid-acting insulin begins working within 15 minutes, so it can be injected right before a meal. Short-acting insulin requires a half-hour wait before the meal can begin.

TABLE 26-7 Insulin Preparations

Form of Insulin	Common Preparations	Onset of Action	Peak Activity	Duration of Action
Rapid acting	Lispro Aspart Glulisine	5 to 15 minutes	30 to 90 minutes	3 to 5 hours
Short acting	Regular	30 minutes	2 to 3 hours	5 to 8 hours
Intermediate acting	NPH	2 to 4 hours	5 to 10 hours	10 to 16 hours
Long acting	Glargine Detemir	1 to 2 hours	Steady effects	24 hours or longer
Insulin mixtures (with sample ratios)	NPH/regular (70:30) NPH/regular (50:50)	Variable; depends on formulation	Variable; depends on formulation	Variable; depends on formulation

ing. With fewer injections, the timing of both meals and injections must be similar from day to day to avoid periods of insulin deficiency or excess.

A person using intensive therapy must learn to accurately determine the amount of insulin to inject before each meal. The amount required depends on the premeal blood glucose level, the carbohydrate content of the meal, and the person's body weight and sensitivity to insulin. To determine insulin sensitivity, a person keeps careful records of food intake, insulin dosages, and blood glucose levels. Eventually, these records are analyzed by medical personnel to determine the appropriate **carbohydrate-to-insulin ratio** for that individual, which assists in calculating insulin doses at mealtime. Intensive therapy allows for substantial variation in food intake and lifestyle, but it requires frequent testing of blood glucose levels and a good understanding of carbohydrate counting.

After insulin therapy is initiated, persons with type 1 diabetes may experience a temporary remission of disease symptoms and a reduced need for insulin, known as the "honeymoon phase." The remission is due to a temporary improvement in pancreatic function and may last for several weeks or months.[43] It is important to anticipate this period of remission to avoid insulin excess. In all cases, diabetes eventually returns, and the patient must reinstate full insulin treatment.

© Mark Clarke/Science Photo Library/Photo Researchers, Inc.

Children often become adept at administering the insulin they require.

Insulin Regimen for Type 2 Diabetes Approximately 27 percent of people diagnosed with type 2 diabetes are treated with insulin therapy.[44] Although initial treatment of type 2 diabetes may involve diet therapy, physical activity, and oral antidiabetic medications, long-term results with these treatments are often disappointing. As the disease progresses, pancreatic function worsens, and many individuals require insulin therapy to maintain glycemic control.

Many possible regimens can be used to control type 2 diabetes. Some persons may be treated with insulin alone, whereas others may use insulin in combination with other antidiabetic agents. Many patients need only one or two daily injections. Some regimens involve a mixture of rapid- and intermediate-acting insulin in the morning and an injection of intermediate- or long-acting insulin at dinner or before bedtime. In other cases, only a single injection of intermediate- or long-acting insulin may be needed at bedtime.[45] Doses and timing are adjusted according to the results of blood glucose self-monitoring.

Insulin Therapy and Hypoglycemia Hypoglycemia is the most common complication of insulin treatment, although it may also result from the use of some oral antidiabetic drugs. It most often results from intensive insulin therapy, because the attempt to attain near-normal blood glucose levels increases the risk of overtreatment.

Hypoglycemia can be corrected with the immediate intake of glucose or a carbohydrate-containing food. Usually, 15 to 20 grams of carbohydrate ◆ can relieve hypoglycemia in about 15 minutes, although patients should retest their blood glucose levels after 15 minutes in case additional treatment is necessary.[46] Foods that provide pure glucose yield a better response than foods that contain other sugars, such as sucrose or fructose. People using insulin are usually advised to carry glucose tablets or a source of carbohydrate that can be readily ingested. Those at risk of severe hypoglycemia are often given prescriptions for the hormone glucagon, which can be injected by caregivers in case of unconsciousness.

◆ Each of the following sources provides approximately 15 g of carbohydrate:
- Glucose tablets: 2 to 3 tablets
- Table sugar: 4 tsp
- Honey: 1 tbs
- Jelly beans: 15 small
- Grape juice, unsweetened: 1/2 c
- Orange juice, canned: 1/2 c

Fasting Hyperglycemia Insulin therapy sometimes must be adjusted to prevent fasting hyperglycemia, which has three possible causes. The usual cause is a waning of insulin action during the night due to insufficient insulin. A second possibility, known as the **dawn phenomenon**, occurs when blood glucose levels increase in the morning due to the early morning secretion of growth hormone, which counteracts insulin's actions. Less frequently, fasting hyperglycemia develops as a result of nighttime hypoglycemia, which causes hormonal responses that stimulate glucose production; the resulting condition is known as **rebound hyperglycemia.** Whatever the cause, fasting hyperglycemia can be treated by adjusting the dose or formulation of insulin administered in the evening.

carbohydrate-to-insulin ratio: the amount of carbohydrate that can be handled per unit of insulin. On average, every 15 grams of carbohydrate requires about 1 unit of rapid- or short-acting insulin.

Antidiabetic Drugs

Treatment of type 2 diabetes often requires the use of oral medications and injectable drugs other than insulin. These drugs can improve hyperglycemia by several modes of action: they can stimulate insulin secretion, suppress glucagon secretion, decrease insulin resistance, reduce glucose production in the liver, improve glucose utilization in tissues, delay stomach emptying, or delay carbohydrate absorption. Treatment may involve the use of a single medication (monotherapy) or a combination of several medications (combination therapy). By utilizing several mechanisms at once, combination therapy achieves more rapid and sustained glycemic control than is possible with monotherapy. Table 26-8 lists examples of antidiabetic drugs, and the Diet-Drug Interactions feature lists their nutrition-related effects. Because medications cannot replace the benefits offered by dietary modifications and physical activity, persons with diabetes should be advised to continue both.

Physical Activity and Diabetes Management

Regular physical activity can improve glycemic control considerably and is therefore a central feature of diabetes management. A regular exercise program improves insulin sensitivity, which can reduce insulin requirements. Physical activity also benefits other aspects of health, including blood lipid levels, blood pressure, body weight, and cardiovascular functioning. People with diabetes are encouraged to regularly perform both aerobic activity and resistance exercise unless contraindicated. They should undertake at least 150 minutes of moderate-intensity activity and/or 90 minutes of vigorous activity each week. In addition, they should participate in a resistance exercise program that targets all major muscle groups three times weekly.[47]

Physical Activity and Insulin Therapy People who do not have diabetes maintain blood glucose levels during physical activity because their normal hormonal responses—a fall in insulin levels and increased secretion of glucagon and epinephrine—promote glucose production in the liver. In people who use insulin, the natural hormonal balance is upset: blood glucose levels drop during activity because injected insulin promotes rapid consumption of glucose by exercising muscles and also blocks glucose synthesis by the liver. For this reason, insulin should not be injected immediately before exercise, because it can lead to hypoglycemia. Conversely, a complete lack of insulin contributes to hyperglycemia, because liver glucose production is unchecked.

TABLE 26-8 Antidiabetic Drugs

Drug Category	Common Examples	Mode of Action
Alpha-glucosidase inhibitors	Acarbose, miglitol	Delay carbohydrate absorption
Amylin analogs (injected)	Pramlintide	Suppress glucagon secretion, delay stomach emptying, suppress appetite
Biguanides	Metformin	Inhibit liver glucose production, improve glucose utilization
D-phenylalanine derivatives	Nateglinide	Stimulate insulin secretion by the pancreas
DPP-4 inhibitors	Sitagliptin	Improve insulin secretion, suppress glucagon secretion, delay stomach emptying
Incretin mimetics (injected)	Exenatide	Improve insulin secretion, suppress glucagon secretion, delay stomach emptying
Meglitinides	Repaglinide	Stimulate insulin secretion by the pancreas
Sulfonylureas	Chlorpropamide, glipizide, glyburide, tolbutamide	Stimulate insulin secretion by the pancreas
Thiazolidinediones	Pioglitazone, rosiglitazone	Decrease insulin resistance

DIET-DRUG INTERACTIONS

Check this table for notable nutrition-related effects of the medications discussed in this chapter.

	Gastrointestinal Effects	Interactions with Dietary Substances	Metabolic Effects
Sulfonylureas	Nausea, vomiting, cramps, diarrhea.	Avoid using with alcohol due to a toxic reaction that causes flushing, throbbing head and neck pain, shortness of breath, palpitations, and sweating. Avoid using with dietary supplements that contain ginseng, garlic, fenugreek, coriander, celery, as they may increase risk of hypoglycemia.	Hypoglycemia, weight gain, allergic skin reactions.
Biguanides (metformin)	Abdominal pain, nausea, vomiting, gas, cramps, diarrhea, metallic taste, anorexia.	—	Asymptomatic vitamin B_{12} deficiency.
Thiazolidinediones	—	—	Weight gain, fluid retention, edema, anemia.
Alpha-glucosidase inhibitors	Abdominal pain, nausea, gas, cramps, diarrhea.	—	Elevated liver enzymes, hyperbilirubinemia.

People with type 1 diabetes must carefully adjust food intake and insulin therapy to prevent hypoglycemia during physical activity. They should check their blood glucose levels both before and after an activity. Insulin doses that precede exercise often need to be reduced substantially. If blood glucose is below 100 mg/dL, the individual should consume carbohydrate before beginning the activity. Additional carbohydrate may be needed during or after prolonged activity or even several hours after the activity is completed. The individual should avoid strenuous exercise if fasting blood glucose levels are 250 mg/dL or higher and should avoid all types of physical activity when blood glucose levels are 300 mg/dL or higher or ketosis is present.[48] Predicting the precise adjustments in diet and insulin becomes easier as a person gains experience in maintaining glycemic control.

Physical Activity in Type 2 Diabetes Regular physical activity can improve the metabolic outcomes associated with type 2 diabetes, including problems with blood glucose, blood lipids, and blood pressure. People with type 2 diabetes are often overweight and sedentary, however, and many develop complications during the course of disease. Before an exercise program is planned, a medical evaluation should screen for problems that may be aggravated by certain activities. Complications involving the heart and blood vessels, eyes, kidneys, feet, and nervous system may limit the types of activity recommended.

Only mild or moderate exercise may be prescribed at first. For obese, inactive persons, a short walk at a comfortable pace may be the first activity suggested. Persons with retinopathy should avoid heavy lifting or straining, which may raise blood pressure and damage eye tissue. Persons with nephropathy often have reduced capacity for physical activity, and strenuous exercise is discouraged. Peripheral neuropathy precludes repetitive weight-bearing exercises such as jogging and step exercises, because these activities may lead to foot ulcerations. The use of protective foot gear, such as gel soles or air midsoles and socks that prevent blisters, can help to prevent foot trauma. To prevent dehydration,

which can adversely affect blood glucose levels and heart function, proper hydration should be encouraged before and during exercise.[49]

Sick-Day Management

Illness, infection, or injury can cause hormonal changes that raise blood glucose levels and increase the risk of developing diabetic ketoacidosis or the hyperosmolar hyperglycemic state. Hence, individuals with diabetes are counseled about sick-day management along with other self-care measures for diabetes. During illness, patients with diabetes should measure blood glucose levels and ketone levels in blood or urine several times daily. They should continue to take antidiabetic medications, including insulin, as prescribed. If over-the-counter drugs are necessary, they should use only those that are sugar- and alcohol-free. Because some medications (such as decongestants) needed during illness can raise blood glucose levels and others (such as medications that contain aspirin) can interact with oral antidiabetic drugs, patients should check with health care providers before using an unfamiliar drug.[50]

During illness, individuals with diabetes should consume their usual diet, if possible. If appetite is poor, they should choose easy-to-manage foods and beverages that provide the prescribed amount of carbohydrate at each meal. Foods that are easily tolerated include toast, crackers, soup, yogurt, fruit, fruit juices, frozen juice bars, and carbohydrate-sweetened beverages. To prevent dehydration, especially if vomiting or diarrhea are present, liquids should be ingested in adequate amounts throughout the day.

IN SUMMARY

Diabetes treatment includes medical nutrition therapy, the use of insulin or other antidiabetic medications, and appropriate physical activity. Glycemic control is most often evaluated by monitoring blood glucose levels and glycated hemoglobin. Carbohydrate intake is the main factor that influences blood glucose levels after meals. The total amount of carbohydrate ingested is more important than the type of carbohydrate consumed. Carbohydrate counting is widely used in menu planning and can be taught at different levels of complexity, depending on individual needs and abilities. Insulin therapy is required for patients who are unable to produce sufficient insulin and may be used in both type 1 and type 2 diabetes. Various medications can improve insulin secretion and effectiveness, suppress glucagon secretion, reduce glucose production by the liver, and delay carbohydrate absorption. Physical activity can improve glycemic control and enhance various aspects of general health. The Case Study provides an opportunity to review the factors that influence treatment for a 12-year-old with type 1 diabetes.

Diabetes Management in Pregnancy

Women with diabetes face new challenges during pregnancy. Due to hormonal changes, pregnancy increases insulin resistance and the need for insulin, so maintaining glycemic control may be more difficult. In addition, up to 7 percent of nondiabetic women develop gestational diabetes and require treatment during pregnancy.[51] Women with gestational diabetes are at greater risk of developing type 2 diabetes later in life, and their children are at increased risk of developing obesity and type 2 diabetes as they enter adulthood.

CASE STUDY Child with Type 1 Diabetes

Nora is a 12-year-old girl who was diagnosed with type 1 diabetes 2 years ago. She practices intensive therapy and has had the support of her parents and an excellent diabetes management team. With their help, Nora has been able to assume the bulk of the responsibility for her diabetes care and has managed to control her blood glucose remarkably well. In the last few months, however, Nora has been complaining bitterly about the impositions diabetes has placed on her life and her interactions with friends. Sometimes she refuses to monitor her blood glucose levels, and she has skipped insulin injections a few times. Recently, Nora was admitted to the emergency room complaining of fever, nausea, vomiting, and intense thirst. The physician noted that Nora was confused and lethargic. A urine test was positive for ketones, and her blood glucose levels were 400 mg/dL. The diagnosis was diabetic ketoacidosis.

1. Describe the metabolic events that lead to ketoacidosis. Were Nora's symptoms and laboratory tests consistent with the diagnosis?
2. Review Table 26-4, and consider the advantages and disadvantages that intensive therapy might have for Nora.
3. Discuss how Nora's age might influence her ability to cope with and manage her diabetes. Why might she feel that diabetes is disrupting her life? What suggestions may help?
4. Review the complications associated with long-term diabetes. How might you explain the importance of glycemic control to a 12-year-old girl?

© Lester Lefkowitz/Corbis

Glycemic control during pregnancy offers the best chance of a safe delivery and a healthy infant.

A pregnancy complicated by diabetes increases health risks for both mother and fetus. Uncontrolled diabetes is linked with an increased rate of miscarriage. Incidences of birth defects and fetal deaths are higher than normal. Newborns are more likely to suffer from respiratory distress and to develop metabolic problems such as hypoglycemia, jaundice, and hypocalcemia. Women with type 2 diabetes and gestational diabetes often deliver babies with **macrosomia** (abnormally large bodies), which makes delivery more difficult and can result in birth trauma or the need for a cesarean section.

Pregnancy in Type 1 or Type 2 Diabetes

Women with diabetes who achieve glycemic control at conception and during the first trimester of their pregnancy substantially reduce the risks of birth defects and spontaneous abortion. For this reason, it is recommended that women contemplating pregnancy receive preconception care to avoid the complications associated with poorly controlled diabetes.[52] Maintaining glycemic control during the second and third trimesters can minimize the risks of macrosomia and morbidity in newborn infants.

Nutrient requirements during pregnancy are generally similar for women with and without diabetes. The dietary adjustments suggested for improving glycemic control should be based on a woman's dietary habits and the results of blood glucose monitoring. Regular meals and snacks help to avoid hypoglycemia, which is more likely to occur during pregnancy because glucose is continuously supplied to the fetus. An evening snack is usually required to prevent overnight hypoglycemia and ketosis. Insulin and medication changes are often needed during pregnancy, and the woman may have to adjust her dietary habits further as a result.

Gestational Diabetes

Risk of gestational diabetes is highest in women who have a family history of diabetes, are obese, are in a high-risk ethnic group (Hispanic American, Native

macrosomia (MAK-roh-SOH-mee-ah): the condition of having an abnormally large body; in infants, refers to birth weights of 4000 grams (8 pounds 13 ounces) and above.

American, Asian American, African American, or Pacific Islander), or have previously given birth to an infant weighing over 9 pounds. To ensure that problems are dealt with promptly, physicians routinely test all women for gestational diabetes between 24 and 28 weeks of gestation. In high-risk women, screening should begin prior to pregnancy or soon after conception. Even mild hyperglycemia can have adverse effects on a developing fetus and may lead to complications during pregnancy.[53]

Women with gestational diabetes who are overweight or obese may need to adjust their energy intakes during pregnancy. Although adequate energy is needed for fetal development, a modest kcaloric reduction (about 30 percent less than total energy needs) may improve glycemic control without increasing the risk of ketosis. Restricting carbohydrate to about 40 percent of total energy intake can improve blood glucose levels after meals. Carbohydrate is usually poorly tolerated in the morning; therefore, restricting carbohydrate (to about 30 grams) at breakfast is often necessary. The remaining carbohydrate intake should be spaced throughout the day in several meals and snacks, including an evening snack to prevent ketosis during the night. Regular aerobic activity is often recommended because it can help to improve glycemic control. Women who fail to achieve glycemic goals by diet and exercise alone may need to use insulin or an antidiabetic drug that is safe during pregnancy.[54] The Case Study reviews the connections between gestational diabetes and type 2 diabetes.

CASE STUDY School Counselor with Type 2 Diabetes

Alicia Cordova is a 41-year-old Mexican American woman recently diagnosed with type 2 diabetes. Mrs. Cordova developed gestational diabetes while she was pregnant with her second child. Her blood glucose levels returned to normal following pregnancy, and she was advised to get regular checkups, maintain a desirable weight, and engage in regular physical activity. Although she reports that she does not overeat and that she exercises regularly, she has been unable to maintain a healthy weight. At 5 feet 3 inches tall, Mrs. Cordova currently weighs 155 pounds. She has decided to lose weight and join a gym because she is concerned about the long-term effects of diabetes and the possibility that she may need insulin injections. She is also concerned about her husband and children because they are overweight and not very active. The physician refers Mrs. Cordova to a dietitian to help her plan a diet.

1. What factors in Mrs. Cordova's medical history increase her risk for diabetes? Are her husband and children also at risk?
2. Describe the general characteristics of a diet and exercise program that would be appropriate for Mrs. Cordova. How might weight loss and physical activity benefit her diabetes?
3. If Mrs. Cordova is unable to control her blood glucose with diet and physical activity, what treatment might be suggested? Can you explain to Mrs. Cordova why she would probably not require insulin at this time?
4. What dietary and lifestyle changes may help to prevent diabetes in Mrs. Cordova's husband and children?

IN SUMMARY

Careful management of blood glucose levels before and during pregnancy may reduce complications in mother and infant. Most nutrient requirements during pregnancy are similar for women with and without diabetes. Carbohydrate intake should be distributed into several meals and snacks, including an evening snack to prevent overnight ketosis. Carbohydrate restriction may be recommended, especially in women with gestational diabetes. Moderate energy restriction may help to improve glycemic control in overweight and obese women with gestational diabetes.

Clinical Portfolio

1. Using the carbohydrate-counting method described in the "How to" on pp. 824–825, determine an appropriate carbohydrate intake (in both grams and portions) for a man with type 2 diabetes who requires approximately 2600 kcalories daily. Assume he would benefit from a carbohydrate allowance that is 50 percent of his energy intake. Using information from Tables 26-5 and 26-6, develop a one-day sample menu that is likely to meet his carbohydrate goals. Use the exchange lists in Appendix G to find additional examples of foods to include in your menu.
2. Take a trip to a pharmacy or use information from an online drugstore to price these items: blood glucose meter, test strips for the glucose meter selected, lancets, insulin, and syringes. Determine the approximate cost of insulin and syringes for a person who uses 12 units of short-acting insulin (regular) and 18 units of intermediate-acting insulin (NPH) taken in three injections daily (thus, the insulin requirement is 30 units per day). Also estimate the cost of testing blood glucose three times daily. Approximately how much would these supplies cost per month?

NUTRITION ON THE NET

For further study of topics covered in this chapter, log on to **academic.cengage.com/nutrition/rolfes/UNCN8e**. Go to Chapter 26, then to Nutrition on the Net.

- Visit the American Diabetes Association and the Joslin Diabetes Center to find information on a wide range of topics related to diabetes: **www.diabetes.org** and **www.joslin.org**
- Comprehensive and reliable information about diabetes for both health practitioners and consumers is available from the National Institute of Diabetes and Digestive and Kidney Diseases and the Centers for Disease Control: **www2.niddk.nih.gov** and **www.cdc.gov/diabetes**
- Find out how to become a diabetes educator by visiting the website of the American Association of Diabetes Educators: **www.diabeteseducator.org**

NUTRITION ASSESSMENT CHECKLIST for People with Diabetes Mellitus

Medical History

Check the medical record to determine:

- Type of diabetes
- Duration of diabetes
- Acute and chronic complications
- Conditions, including pregnancy, that may alter treatment

Medications

For people with preexisting diabetes who use antidiabetic drugs (including insulin), note:

- Type of medication
- Administration schedule

Check for use of other medications, including:

- Medications that affect blood glucose levels
- Cholesterol- and triglyceride-lowering medications
- Antihypertensive medications

Dietary Intake

To devise an acceptable meal plan and coordinate medications, obtain:

- An accurate and thorough record of food intake and meal patterns
- An account of usual physical activities

At medical checkups, reassess the person's ability to:

- Maintain an appropriate carbohydrate intake
- Maintain an appropriate energy intake
- Monitor blood glucose levels at home
- Adjust insulin and diet to accommodate sick days
- Use appropriate foods to treat hypoglycemia

Anthropometric Data

Take accurate baseline height and weight measurements as a basis for:

- Appropriate energy intake
- Initial insulin therapy

Periodically reassess height and weight for children and weight for adults and pregnant women to ensure that the meal plan provides an appropriate energy intake.

Laboratory Tests

Monitor the success of diabetes treatment using these tests:

- Blood lipid concentrations
- Blood or urinary ketones
- Fructosamine, if necessary
- Glycated hemoglobin
- Urinary protein (microalbuminuria)

Physical Signs

Look for physical signs of:

- Dehydration, especially in older adults
- Foot ulcers
- Nerve damage
- Vision problems

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Describe the symptoms that develop as a consequence of hyperglycemia. How is diabetes diagnosed? (pp. 811–813)
2. Compare the features of the two main types of diabetes. Describe gestational diabetes. (pp. 813–814)
3. Discuss the acute complications that may arise in uncontrolled diabetes. (pp. 815–817)
4. Describe the macrovascular and microvascular complications that develop from prolonged exposure to high blood glucose concentrations. Discuss the problems associated with diabetic neuropathy. (pp. 817–818)
5. What are the goals of medical and nutrition therapy for people with diabetes? Explain how diabetes treatment is evaluated. (pp. 818–820)
6. Discuss the dietary recommendations for people with diabetes. Describe the meal-planning strategies they can use to control carbohydrate intakes. (pp. 821–825)
7. Describe the insulin regimens for type 1 and type 2 diabetes. Explain how insulin therapy is coordinated with food intake and physical activity. (pp. 826–829)
8. Discuss the modes of action of the various antidiabetic drugs. (p. 828)
9. What are the risks of poorly controlled diabetes during pregnancy? Describe the general recommendations for diabetic women who become pregnant. Describe the dietary adjustments that may be necessary for women with gestational diabetes. (pp. 830–832)

These multiple choice questions will help you review for an exam. Answers can be found on p. 835.

1. Which of the following is characteristic of type 1 diabetes?
   a. Abdominal obesity increases risk.
   b. The pancreas makes little or no insulin.
   c. It is the predominant form of diabetes.
   d. It often arises during pregnancy.
2. Which of the following describes type 2 diabetes?
   a. It is usually an autoimmune disease.
   b. The pancreas makes little or no insulin.
   c. Diabetic ketoacidosis is a common complication.
   d. Chronic complications may develop before it is diagnosed.
3. The chronic complications associated with all types of diabetes result from:
   a. altered kidney function.
   b. infections that deplete nutrient reserves.
   c. weight gain and hypertension.
   d. damage to blood vessels and nerves.
4. Long-term glycemic control is usually evaluated by:
   a. self-monitoring of blood glucose.
   b. testing urinary ketone levels.
   c. measuring glycated hemoglobin.
   d. testing urinary protein levels (microalbuminuria).
5. Regarding dietary carbohydrate, a patient with diabetes should be most concerned about:
   a. consuming the correct quantity of carbohydrate at each meal or snack.
   b. consuming the correct proportion of sugars, starches, and fiber in meals.
   c. avoiding added sugars and kcaloric sweeteners.
   d. choosing meals with ideal proportions of protein, carbohydrate, and fat.
6. Which of the following is true regarding the general use of alcohol in diabetes?
   a. A serving of alcohol is considered part of the carbohydrate allowance.
   b. Alcohol contributes to hyperglycemia and should be avoided completely.
   c. Alcohol can cause hypoglycemia and should therefore be consumed with food if patients use insulin or medications that stimulate insulin secretion.
   d. Patients can use alcohol in unlimited quantities unless they are pregnant.
7. The meal-planning strategy best suited to all people with diabetes is:
   a. carbohydrate counting.
   b. the exchange list system.
   c. following menus and recipes provided by a registered dietitian.
   d. any approach that best helps the patient control blood glucose levels.
8. A patient using intensive insulin therapy is likely to follow a regimen that involves:
   a. twice-daily injections that combine short-, intermediate-, and long-acting insulin in each injection.
   b. a mixture of intermediate- and long-acting insulin injected between meals.
   c. multiple daily injections that supply basal insulin and precise insulin doses at each meal.
   d. the use of both insulin and oral antidiabetic agents.
9. In a person who has previously maintained good glycemic control, hyperglycemia can be precipitated by:
   a. infections or illnesses.
   b. chronic alcohol ingestion.
   c. undertreatment of hypoglycemia.
   d. prolonged exercise.

10. Women with pregnancies complicated by diabetes:
    a. generally benefit from larger meals and a snack at bedtime.
    b. often need less carbohydrate at breakfast.
    c. need more carbohydrate than women with diabetes who are not pregnant.
    d. need more kcalories to support the pregnancy than women without diabetes.

The Metabolic Syndrome

Chapter 26 described how insulin resistance—a reduced sensitivity to insulin in muscle, adipose, and liver cells—can contribute to hyperglycemia and hyperinsulinemia and, eventually, to type 2 diabetes. Insulin resistance is also a central feature of several other conditions, including the **metabolic syndrome,** a condition that raises the risk of developing cardiovascular diseases (CVD) and type 2 diabetes. The metabolic syndrome is a cluster of at least three of the following: hyperglycemia, obesity, hypertriglyceridemia (elevated blood triglycerides), reduced HDL cholesterol levels, and hypertension (high blood pressure). This highlight describes how the metabolic syndrome is diagnosed, how and why it might develop, its consequences, and current treatment approaches. The accompanying glossary defines the relevant terms.

Prevalence of the Metabolic Syndrome

Table H26-1 lists the laboratory values used to identify the metabolic syndrome, which currently affects an estimated 29 percent of the adult population in the United States.[1] As Figure H26-1 shows, the prevalence of the metabolic syndrome increases with age. Risk also varies among ethnic groups: Hispanic Americans have the highest incidence in the United States, with an overall prevalence of 36 percent.[2] Although the precise cause of the metabolic syndrome is not known, the close relationship between abdominal obesity and insulin resistance suggests that the current obesity crisis in the United States may be partly responsible for the high prevalence of the condition.

Obesity and the Metabolic Syndrome

Excessive abdominal fat induces a number of metabolic changes that lead to insulin resistance, which then leads to hyperglycemia and other abnormalities. The following sections explore several of these relationships.

Effects of Obesity on Insulin Action

Adipose cells that reside in the abdominal region are more metabolically active than adipose cells elsewhere.[3] Within these cells, triglycerides break down more rapidly, increasing fatty acid levels in the blood. The higher fatty acid concentrations inhibit the actions of insulin receptors, the proteins that recognize and bind insulin at cell surfaces.[4] Unless the pancreas can secrete enough

TABLE H26-1 Features of the Metabolic Syndrome

Metabolic syndrome is diagnosed when a person has three or more of the following symptoms.

Symptom	Diagnostic Criteria
Hyperglycemia	Fasting plasma glucose ≥100 mg/dL
Abdominal obesity	Waist circumference >40" in men, >35" in women
Hypertriglyceridemia	≥150 mg/dL
Reduced HDL cholesterol	<40 mg/dL in men, <50 mg/dL in women
Hypertension	≥130/85 mm Hg

GLOSSARY

adiponectin (AH-dih-poe-NECK-tin): a hormone produced by adipose cells that improves insulin sensitivity.

fibrinogen (fye-BRIN-oh-jen): a liver protein that promotes blood clot formation.

metabolic syndrome: a cluster of interrelated clinical symptoms, including obesity, insulin resistance, high blood pressure, and abnormal blood lipids, which together increase cardiovascular disease risk twofold to threefold; also known as *syndrome X* or *insulin resistance syndrome.*

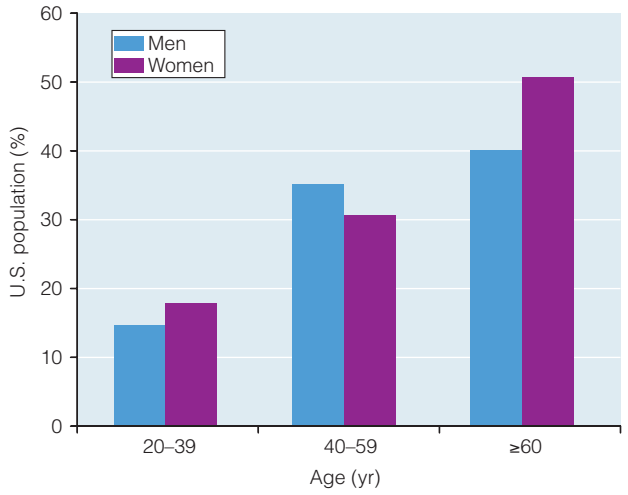
nitric oxide: a compound produced by blood vessel cells that helps to regulate blood vessel activity, including dilation and constriction.

plasminogen activator inhibitor-1: a protein that promotes blood clotting by inhibiting blood clot degradation within blood vessels.

resistin (re-ZIST-in): a hormone produced by adipose cells that induces insulin resistance.

Reminder: Cytokines are signaling proteins produced by the body's cells.

FIGURE H26-1 Prevalence of Metabolic Syndrome in the U.S. Population



insulin to compensate, glucose uptake from the blood is reduced, contributing to hyperglycemia.

Obesity can also alter production of the hormones and proteins made in adipose cells.[5] For example, obesity causes a reduced secretion of **adiponectin,** a hormone that improves insulin sensitivity. Conversely, **resistin,** a hormone that contributes to insulin resistance, is released in greater amounts. Enlarged adipose cells also boost their production of certain cytokines that induce the synthesis of liver proteins that promote inflammation and blood coagulation.[6] People who are obese often have elevated levels of C-reactive protein, a marker of inflammation linked to an increased risk of CVD.

Obesity and Hypertension

Obesity increases the risk of developing high blood pressure, a common component of the metabolic syndrome. Both insulin resistance and hyperinsulinemia may be implicated in raising blood pressure.[7] Insulin resistance interferes with the normal relaxation and dilation of blood vessels. Hyperinsulinemia promotes reabsorption of sodium by the kidneys, resulting in fluid retention and increased blood volume. These effects contribute to an increase in blood pressure.

Obesity and Hypertriglyceridemia

Abdominal obesity is frequently associated with blood lipid abnormalities.[8] Increases in body weight are linked with higher triglyceride and LDL cholesterol levels and lower HDL cholesterol levels. As a result of obesity, adipose cells are less responsive to insulin and release more fatty acids into the bloodstream. At the same time, they are less able to extract and store triglycerides from chylomicrons and VLDL. To keep up with the greater influx of fatty acids, the liver must accelerate its production of VLDL, and hypertriglyceridemia develops.

Metabolic Syndrome and CVD Risk

As mentioned, individuals with the metabolic syndrome are at increased risk of developing cardiovascular diseases. The disorders that characterize the metabolic syndrome—obesity, lipid abnormalities, and hypertension—are all independent risk factors for CVD. In addition, both insulin resistance and elevated lipoprotein levels can cause damage to blood vessels, promoting inflammation and accelerating the progression of atherosclerosis.[9] Blood vessel inflammation induces liver secretion of **fibrinogen,** a protein that promotes blood clot formation (recall that blood clotting in arteries can lead to a heart attack or stroke). C-reactive protein, which is elevated by both inflammation and obesity, inhibits **nitric oxide** production by blood vessel cells, an effect that impairs blood vessel activity and also promotes blood clotting.[10] Another procoagulant factor—**plasminogen activator inhibitor-1**—is overproduced as a consequence of both obesity and hyperinsulinemia. Thus, the combined effect of these multiple abnormalities can worsen atherosclerosis and increase the risks of developing heart attack and stroke.

Treatment of the Metabolic Syndrome

The metabolic syndrome is primarily treated with dietary and lifestyle changes, with the goal of correcting abnormalities that increase CVD risk.[11] In most individuals, a combination of weight loss and physical activity can improve insulin resistance, blood pressure, and blood lipid levels. Additional dietary strategies depend on a patient's specific symptoms. If dietary and lifestyle changes are not successful, medications may be prescribed. Because effective treatment requires lifelong commitment, health care providers should work with patients to develop a treatment plan that they are willing to adopt.

Dietary Management

Weight reduction is often recommended for obese individuals, and even a small weight loss (10 to 20 pounds) can improve symptoms. Many people find it difficult to achieve and maintain weight loss, however, and should be encouraged to make other dietary changes that can improve their health. In individuals with hypertriglyceridemia, the general recommendation is to reduce intake of added sugars and refined grain products (soda, juices, white bread, sweetened cereal, and desserts) and increase servings of whole grains and foods high in fiber (whole wheat bread, oatmeal, legumes, fruits, and vegetables).[12] In some people, carbohydrate restriction may help to reduce blood triglyceride levels and improve hyperglycemia.[13] Including fish in the diet each week may also improve triglyceride levels. Individuals with hypertension are encouraged to reduce sodium intake and increase consumption of fruits and vegetables and low-fat milk products.

A diet low in saturated fat, *trans* fats, and cholesterol can help to reduce LDL cholesterol levels. Chapter 27 includes additional information about dietary modifications that can reduce CVD risk.

Physical Activity

Regular physical activity helps with weight management and may also improve blood lipid concentrations, hypertension, and insulin resistance—all changes that can reduce the risk of developing CVD. A regular exercise program can also prevent or delay the onset of diabetes in persons at risk.[14] A program that includes both aerobic exercise and strength training is best. A minimum of 30 minutes of moderate aerobic activity (brisk walking, jogging, or cycling) daily is suggested, although longer periods (1 hour daily) are recommended for weight control. A sedentary lifestyle can worsen the progression of metabolic syndrome and should be discouraged.

Drug Therapy

If dietary and lifestyle changes are unsuccessful, medications may be prescribed to correct hypertriglyceridemia and hypertension (Chapter 27 provides details). Insulin resistance is not routinely treated with drug therapy in nondiabetic patients due to insufficient evidence that the medications can benefit individuals with the metabolic syndrome.[15]

© Rolf Bruderer/Corbis

Regular exercise can reduce the risks of developing the metabolic syndrome, cardiovascular diseases, and type 2 diabetes.

As explained in this highlight, the metabolic syndrome consists of a cluster of related disorders that increase the risk for developing CVD. Whereas the common features of the metabolic syndrome are independent risk factors for CVD, in combination they may raise risk twofold to threefold. Treatment of the metabolic syndrome emphasizes dietary and lifestyle changes. The following chapter provides additional information about the dietary and lifestyle changes that can reduce CVD risk.

Nutrition in the Clinical Setting

Each heartbeat sends oxygen-rich blood to the body's tissues. When the functions of the heart and blood vessels are disturbed, as is common in cardiovascular diseases, the disrupted blood supply hinders the ability of cells to carry out their metabolic functions. At first, people with cardiovascular disease may not realize that their weakness, fatigue, or shortness of breath are symptoms of a cardiovascular condition. When their condition worsens, however, the complications can be disabling and interfere with many aspects of daily life.

CHAPTER 27

Cardiovascular Diseases

CHAPTER OUTLINE

Atherosclerosis • Consequences of Atherosclerosis • Development of Atherosclerosis • Causes of Atherosclerosis

Coronary Heart Disease (CHD) • Symptoms of Coronary Heart Disease • Evaluating Risk for Coronary Heart Disease • Therapeutic Lifestyle Changes for Lowering CHD Risk • Lifestyle Changes for Hypertriglyceridemia • Vitamin Supplementation and CHD Risk • Drug Therapies for CHD Prevention • Treatment of Heart Attack

Hypertension • Factors That Influence Blood Pressure • Factors That Contribute to Hypertension • Treatment of Hypertension

Heart Failure • Consequences of Heart Failure • Medical Management of Heart Failure

Stroke • Stroke Prevention • Stroke Management

HIGHLIGHT 27 Feeding Disabilities

Cardiovascular disease (CVD) is a general term describing diseases of the heart and blood vessels. ◆ **Coronary heart disease (CHD),** the most common form of CVD, is caused by atherosclerosis in the coronary arteries that supply blood to the heart muscle. If atherosclerosis interferes with blood flow in these arteries, the resulting deprivation of oxygen and nutrients can destroy heart tissue and cause a **myocardial infarction (MI)**—a **heart attack**. When the blood supply to brain tissue is blocked, a **stroke** occurs. Both heart attack and stroke may result in disablement or death. This chapter describes these and other cardiovascular disorders. Figure 27-1 on p. 842 shows the percentages of deaths resulting from all types of CVD. The glossary on p. 842 defines some common terms related to CVD.

◆ Cardiovascular disease was introduced in Chapter 5 (see p. 157) and discussed further in Highlight 15.

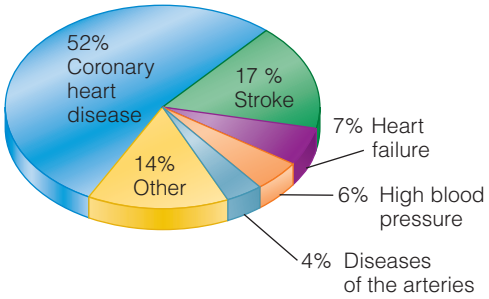
Cardiovascular disease is responsible for approximately 36 percent of deaths in the United States, claiming more lives than the next four leading causes of death combined.[1] Although many people assume that heart conditions are men's diseases, more women than men die each year from the various types of CVD. Furthermore, CVD is a global health issue; it is the leading cause of death in Europe and contributes to over 29 percent of deaths worldwide.[2]

Atherosclerosis

In atherosclerosis, ◆ sometimes called "hardening of the arteries," the artery walls become progressively thickened due to an accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue, collectively known as **plaque.** Plaque can exist in a stable form that does not cause complications or an unstable form called **vulnerable plaque.** Vulnerable plaque has only a thin, fibrous barrier be-

◆ Atherosclerosis is the most common form of *arteriosclerosis,* a more general term for arterial diseases that are characterized by abnormally thickened walls and lost elasticity.

FIGURE 27-1 Percentage Breakdown of Deaths from Cardiovascular Diseases in the United States, 2004



SOURCE: W. Rosamond and coauthors, Heart disease and stroke statistics—2008 update: A report from the American Heart Association Statistics Committee and Stroke Statistics Subcommittee, *Circulation* 117 (2008): epub 17 Dec 2007 (DOI 10.1161/CIRCULATIONAHA.107.187998); site visited January 2, 2008.

tween its lipid-rich core and the arterial lumen.[3] It is highly susceptible to rupture, which then promotes blood clot formation **(thrombosis)** within the artery.

Consequences of Atherosclerosis

As atherosclerosis worsens, it can eventually narrow the lumen of an artery and interfere with blood flow. If the plaque ruptures and results in thrombosis, the blood clot **(thrombus)** may enlarge in time and ultimately obstruct blood flow. A portion of a clot can also break free **(embolus)** and travel through the circulatory system until it lodges in a narrowed artery and shuts off blood flow to the surrounding tissue **(embolism).** Most complications of atherosclerosis result from the deficiency of blood and oxygen within the tissue served by an artery **(ischemia).**

Atherosclerosis can affect almost any organ or tissue in the body, and accordingly is a major cause of disablement or death. Obstructed blood flow in the coronary arteries can cause pain or discomfort in the chest and surrounding regions **(angina pectoris)** or lead to a heart attack. Obstructed blood flow to the brain can cause injury or destruction to brain tissue, or a stroke. Inadequate blood circulation in the legs can cause fatigue and pain while walking, known as **intermittent claudication.** Blockage of the arteries that supply the kidneys can result in kidney disease or even acute kidney failure.

Atherosclerosis is the most common cause of an **aneurysm**—an abnormal bulge in a weakened blood vessel. Plaque can weaken the blood vessel wall, and eventually the pressure of blood flow can cause the weakened region to stretch and balloon outward. Aneurysms can rupture and lead to massive bleeding and death, particularly when a large vessel such as the aorta is affected. In the arteries of the brain, an aneurysm may lead to bleeding within the brain, a coma, or a stroke.

Development of Atherosclerosis

Atherosclerosis begins to develop as early as childhood or adolescence and usually progresses over several decades before symptoms develop. It initially arises in response to minimal but chronic injuries that damage the inner arterial wall. The first lesions tend to develop in regions where the arteries branch or bend because

GLOSSARY OF TERMS RELATED TO CARDIOVASCULAR DISEASE

aneurysm (AN-you-rih-zum): an abnormal enlargement or bulging of a blood vessel (usually an artery) caused by damage to or weakness in the blood vessel wall.

angina (an-JYE-nah or AN-ji-nah) **pectoris:** a condition caused by ischemia in the heart muscle that results in discomfort or dull pain in the chest region. The pain often radiates to the left shoulder and arm or to the back, neck, and lower jaw.

cardiovascular disease (CVD): a general term describing diseases of the heart and blood vessels.
- **cardio** = heart
- **vascular** = blood vessels

coronary heart disease (CHD): a chronic, progressive disease characterized by obstructed blood flow in the coronary arteries; also called *coronary artery disease.*

embolism (EM-boh-lizm): the obstruction of a blood vessel by an embolus, causing sudden tissue death.
- **embol** = to insert, plug

embolus (EM-boh-lus): an abnormal particle, such as a blood clot or air bubble, that travels in the blood.

intermittent claudication (claw-dih-KAY-shun): severe pain and weakness in the legs (especially the calves) that is caused by inadequate blood supply to the muscles; it usually occurs with walking and subsides during rest.

ischemia (iss-KEE-mee-a): inadequate blood supply within tissues due to obstructed blood flow in the arteries.

myocardial (MY-oh-CAR-dee-al) **infarction** (in-FARK-shun), or **MI:** death of heart muscle caused by a sudden reduction in coronary blood flow; also called a *heart attack* or *cardiac arrest.*
- **myo** = muscle
- **cardial** = heart
- **infarct** = tissue death

plaque (PLACK): an accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue in blood vessels.

stroke: a sudden injury to brain tissue resulting from impaired blood flow through an artery that supplies blood to the brain; also called a *cerebrovascular accident.*
- **cerebro** = brain

thrombosis (throm-BOH-sis): the formation or presence of a blood clot in blood vessels. A *coronary thrombosis* occurs in a coronary artery, and a *cerebral thrombosis* occurs in an artery that supplies blood to the brain.
- **thrombo** = clot

thrombus: a blood clot formed within a blood vessel that remains attached to its place of origin.

vulnerable plaque: a form of plaque, susceptible to rupture, that is lipid-rich and has only a thin, fibrous barrier between the arterial lumen and the plaque's lipid core.

the blood flow is disturbed in those areas (see Figure H15-1 in Highlight 15, p. 555). The damage to the artery attracts monocytes, ◆ T cells, and platelets to the region. The monocytes slip under the artery's thin layer of **endothelial cells** and engulf LDL (low-density lipoprotein) cholesterol, ◆ becoming **foam cells;** these fat-laden foam cells collect along the artery wall, creating regions known as *fatty streaks* (see Figure 27-2). Next, the smooth muscle cells in the arterial tissue begin to divide, ingest LDL particles, and produce fibrous connective tissue. The thickening plaque accumulates calcium, and the cholesterol within the lipid core may crystallize and harden. The processes involved in atherosclerosis occur in response to cytokines and other signaling molecules produced by the white blood cells and endothelial cells.[4]

As atherosclerosis progresses, the artery may expand outward to accommodate the plaque, such that a decrease in the lumen diameter does not occur.[5] In other cases, the accumulating plaque causes narrowing, rather than expansion, of the artery. Although arteries that expand are less likely to interfere with blood flow, they usually are associated with the unstable vulnerable plaque, which is more likely to rupture, induce clotting, and increase the risk of heart attack or stroke. The arteries that accommodate plaque only by narrowing may impede blood flow, but they generally have a more stable plaque structure, with a lower lipid content and a thicker barrier between the plaque and arterial lumen. The discovery of variations in plaque anatomy may help to explain why some CVD treatments can dramatically reduce the risk of heart attack and stroke even when plaque volume and the lumen diameter do not change.[6]

◆ Reminder: *Monocytes* are phagocytic white blood cells that circulate in the blood. Once they enter tissues, they become macrophages (see Highlight 17).

◆ Reminder: LDL (low-density lipoproteins) transport cholesterol in the blood.

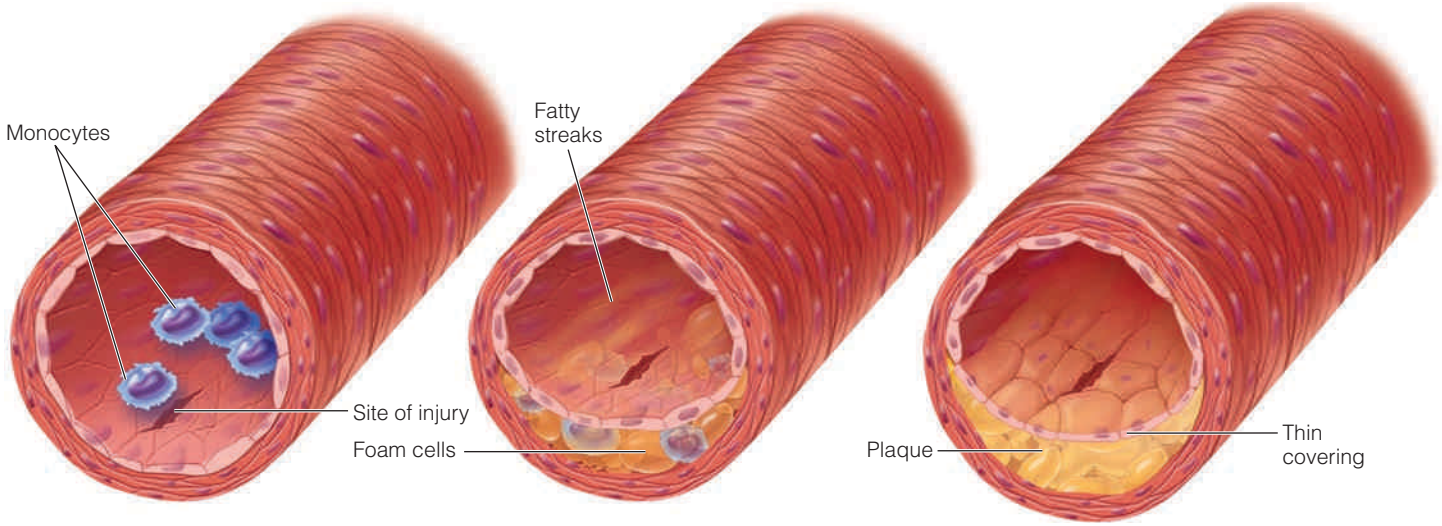
Causes of Atherosclerosis

The reasons why atherosclerosis develops and progresses are complex. Generally, the factors that initiate atherosclerosis either cause direct damage to the artery

endothelial cells: the type of cells that line the blood vessels, lymphatic vessels, and body cavities.

foam cells: swollen cells in the artery wall that accumulate lipids.

FIGURE 27-2 Stages of Plaque Progression



Monocytes—phagocytic white blood cells—circulate in the bloodstream and respond to injury on the artery wall.

Monocytes slip under blood vessel cells and engulf LDL cholesterol, becoming foam cells. The thin layers of foam cells that develop on artery walls are known as *fatty streaks.*

A fatty streak thickens and forms plaque as it accumulates additional lipids, smooth muscle cells, connective tissue, and cellular debris.

The artery may expand to accommodate plaque. When this occurs, the plaque that develops often contains a large lipid core with a thin, fibrous covering and is vulnerable to rupture and thrombosis.

wall or allow lipid materials to penetrate its surface. The factors that promote the progression of atherosclerosis and the development of complications typically induce plaque rupture and blood coagulation.

Inflammation and Infection Plaque formation is an inflammatory response to an injury on the artery wall, so the body's immune system is directly involved in its development.[7] ◆ There is also evidence that a persistent infection within the body may contribute to plaque formation. A number of different bacterial and viral antigens have been identified in plaque.[8]

◆ C-reactive protein, an acute-phase protein secreted during the inflammatory response, is associated with increased heart disease risk (see Chapter 22).

Shear Stress/Hypertension The stress of blood flow along the artery walls—called shear stress—can cause mechanical damage within the arteries. The resulting inflammatory response can initiate the development of plaque.[9] Hypertension (high blood pressure) intensifies the stress of blood flow on the arterial walls and also induces the production of proinflammatory cytokines in endothelial cells.[10]

Cigarette Smoking Chemicals in smoke (including nicotine) are toxic to endothelial cells, and the resulting damage can initiate plaque development. Smoking also promotes blood clotting, raises LDL cholesterol, and lowers HDL (high-density lipoprotein) cholesterol—effects that can cause atherosclerosis to progress. Another effect of smoking is vasoconstriction, which increases the risk of heart attack and stroke in arteries already narrowed by atherosclerosis. Passive smoking can cause these effects as well.[11]

Elevated LDL and VLDL High blood levels of low-density lipoproteins and very-low-density lipoproteins (VLDL) ◆ promote atherosclerosis, particularly if the lipoproteins are oxidized.[12] Oxidized LDL and VLDL are actively taken up and retained in the artery wall. Oxidation may result from free-radical generation by macrophages and endothelial cells or various enzyme reactions. HDL help prevent the oxidation of LDL and also remove cholesterol from circulation, so low levels of HDL contribute to the development of atherosclerosis. It is not yet known whether the oxidation of dietary lipids contributes significantly to the levels of oxidized LDL and VLDL in the blood. ◆

◆ Reminder: VLDL transport triglycerides in the blood. In clinical practice, VLDL levels are commonly referred to as *blood triglycerides*.

There are distinct subtypes of LDL that vary in size and density. LDL size is inversely associated with heart disease risk: the smallest, most dense LDL are the most **atherogenic** (and more likely to become oxidized), whereas larger, less dense LDL are less atherogenic.[13] People who have small, dense LDL frequently have elevated VLDL and low HDL levels as well. This lipoprotein profile, which is especially prevalent in individuals with metabolic syndrome and type 2 diabetes, is associated with an approximately threefold increased risk of coronary heart disease.[14]

◆ Disorders characterized by abnormal levels of blood lipids are called *hyperlipidemias* or *dyslipidemias*.

Elevated concentrations of a variant form of LDL called *lipoprotein(a)* have been found to speed the progression of atherosclerosis and to raise the risk of various types of CVD.[15] Lipoprotein(a) levels are primarily genetically determined and are influenced to only a minor degree by age and environmental factors. Although pharmacological doses of a form of niacin may lower lipoprotein(a) levels, the benefit of treating lipoprotein(a) is not yet clear.[16]

Diabetes Mellitus Diabetes can initiate and accelerate the development of atherosclerosis in multiple ways. Chronic hyperglycemia leads to the production of advanced glycation end products (AGEs) ◆, which damage the proteins of endothelial cells and thereby upset the functioning of endothelial tissue. AGEs also promote inflammation and cause oxidative stress.[17] By other mechanisms, diabetes increases tendencies for vasoconstriction, plaque rupture, and blood clotting.[18]

◆ Reminder: *Advanced glycation end products* are reactive compounds formed after glucose nonenzymatically attaches to proteins.

Age and Gender Advancing age is strongly associated with atherosclerosis due to the cumulative exposure to risk factors and the degeneration of arterial cells with age. Aging becomes a significant risk factor for men aged 45 or older and for women aged 55 or older. After menopause, women's risk increases because the loss of estrogen reduces arterial defenses against atherosclerosis and causes a rise in LDL cholesterol levels.[19] ◆ Levels of the amino acid homocysteine, which may

◆ Estrogen replacement therapy after menopause has mixed effects on heart disease risk; it can improve endothelial function, lower LDL, and raise HDL, but it can also promote blood clotting.

atherogenic: able to initiate or promote atherosclerosis.

damage artery walls and promote blood clotting, rise with age and are generally higher in men; however, researchers have not determined whether homocysteine is a cause or an effect of the disease process.[20] ◆

◆ Reminder: Blood homocysteine levels are influenced by intakes of folate, vitamin B_{12}, and vitamin B_6 (see Chapter 10).

IN SUMMARY

Atherosclerosis, which is characterized by the buildup of arterial plaque, can lead to complications such as angina pectoris, heart attack, stroke, intermittent claudication, kidney disease, and aneurysms. Plaque is caused by factors that damage the artery wall and promote blood coagulation. Leading causes of plaque formation and progression include inflammation, shear stress, hypertension, cigarette smoking, elevated LDL and VLDL cholesterol levels, reduced HDL cholesterol levels, diabetes, and aging.

Coronary Heart Disease (CHD)

Coronary heart disease (CHD), also called *coronary artery disease,* is the most common type of cardiovascular disease and the leading cause of death in the United States.[21] As mentioned, CHD is characterized by impaired blood flow through the coronary arteries, which may lead to angina pectoris, heart attack, or sudden death. CHD is usually caused by atherosclerosis but occasionally results from **spasm** or inflammatory conditions that cause narrowing of the coronary arteries. Although atherosclerosis can advance enough to fully block an artery, most heart attacks occur with less than 50 percent blockage.[22]

The lifetime risk of developing CHD is 49 percent for men and 32 percent for women.[23] Women typically develop CHD about 10 years later in life than men do, and their incidences of serious complications like heart attack and sudden death lag behind men's by about 20 years.[24] In both genders, CHD can lie dormant for years: over half of sudden deaths from CHD occur without prior symptoms in both men and women.[25]

Symptoms of Coronary Heart Disease

Symptoms of CHD usually arise only after many years of disease progression. In angina pectoris and heart attacks, the pain or discomfort usually occurs in the chest region and may be perceived as a feeling of heaviness, pressure, or squeezing. Pain may radiate to the left arm, shoulders, back, throat, jaws, or teeth. In angina pectoris, the symptoms are often triggered by exertion, persist for several minutes, and subside with rest. In a heart attack, the pain may be severe, last longer, and occur without exertion. Other symptoms of CHD include shortness of breath, nausea, vomiting, sweating, lightheadedness, weakness, and anxiety. In some cases, a feeling of indigestion or lower abdominal pain may occur.[26]

Evaluating Risk for Coronary Heart Disease

Because CHD develops over many years, prevention should begin well before symptoms appear. Population studies have suggested that about 90 percent of people with CHD have at least one of the four classic risk factors: smoking, high LDL cholesterol, high blood pressure, and diabetes.[27] These and other major risk factors that can be modified by changes in diet and lifestyle are listed in Table 27-1; only age, gender, and family history cannot be modified.

CHD Risk Assessment Risk assessment requires several key laboratory measures (see Table 27-2 on p. 846) and a thorough medical history. A complete lipoprotein profile (also called a *blood lipid profile*) includes measures of total cholesterol, LDL

TABLE 27-1 Risk Factors for CHD

Major Risk Factors for CHD (not modifiable)

- Increasing age
- Male gender
- Family history of premature heart disease

Major Risk Factors for CHD (modifiable)

- High blood LDL cholesterol
- Low blood HDL cholesterol
- High blood pressure (hypertension)
- Diabetes
- Obesity (especially abdominal obesity)
- Physical inactivity
- Cigarette smoking
- An "atherogenic" diet (high in saturated fats and low in vegetables, fruits, and whole grains)

NOTE: Risk factors highlighted in color have relationships with diet.
SOURCE: Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III), *Third Report of the National Cholesterol Education Program (NCEP),* NIH publication no. 02-5215 (Bethesda, Md.: National Heart, Lung, and Blood Institute, 2002), pp. II-15–II-20.

spasm: a sudden, forceful, and involuntary muscle contraction.

and HDL cholesterol, and blood triglycerides (a measure of VLDL); it should be obtained every 5 years starting at 20 years of age. Sometimes the ratio of total cholesterol to HDL cholesterol is used to predict CHD risk: a high total cholesterol value suggests elevated LDL cholesterol levels, and a low HDL value is often linked with the multiple risk factors of the metabolic syndrome, including high triglycerides and small, dense LDL. Overweight and obesity predispose to CHD, particularly when abdominal obesity ◆ is present. High blood pressure is a major risk factor; for people over 50 years of age, a high systolic blood pressure is more predictive of CHD risk than is high diastolic blood pressure. Finally, cigarette smoking and the presence of diabetes strongly contribute to CHD risk. The "How to" on p. 847 presents a screening method for assessing a person's 10-year risk of developing CHD that includes some of these risk factors.

◆ Abdominal obesity is suggested by a waist circumference of more than 40 inches for men and more than 35 inches for women.

Blood Cholesterol Levels and CHD Risk Once a person's risks have been identified, treatment focuses on lowering LDL cholesterol. Elevated LDL cholesterol levels are directly related to the development of atherosclerosis, and clinical studies have confirmed that LDL-lowering treatments can successfully reduce CHD mortality rates. CHD is seldom seen in populations that maintain desirable LDL levels.

As mentioned earlier, HDL protect against atherosclerosis, and low HDL levels often coexist with other lipid abnormalities; thus a low HDL value is highly predictive of CHD risk. In addition, some factors that increase CHD risk—obesity, smoking, inactivity, and male gender—also cause a reduction in HDL. It is not known whether raising HDL will help to reduce CHD risk, but weight loss, physical activity, and smoking cessation can all independently help to lower risk.

Treatment Strategies for Lowering LDL Cholesterol The aggressiveness of the LDL cholesterol–lowering treatment depends on a person's level of risk for CHD. The National Cholesterol Education Program (NCEP), developed by a division of the National Institutes of Health, periodically issues treatment guidelines that consider an individual's risk status. The most current guidelines, known as the Adult Treatment Panel III (ATP III), recommend aggressive treatment for patients who already have CHD or a CHD risk equivalent; ◆ the guidelines also include recommendations for people with multiple CHD risk factors. For some people, dietary and lifestyle changes may be the only treatment needed for managing cholesterol levels. The "How to" on pp. 848–849 summarizes the use of the ATP III guidelines in clinical practice.

◆ A *CHD risk equivalent* carries the same risk for a major coronary event as established CHD; examples include type 2 diabetes mellitus and diseases caused by atherosclerosis, such as stroke or aortic aneurysm.

TABLE 27-2 Standards for CHD Risk Assessment

Clinical Measures	Desirable	Borderline Risk	High Risk
Total blood cholesterol (mg/dL)	<200	200–239	≥240
LDL cholesterol (mg/dL)	<100[a]	130–159	160–189[b]
HDL cholesterol (mg/dL)	≥60	40–59	<40
Triglycerides, fasting (mg/dL)	<150	150–199	200–499[c]
Body mass index (BMI)[d]	18.5–24.9	25–29.9	≥30
Blood pressure (systolic and diastolic pressure)	<120/<80	120–139/80–89[e]	≥140/≥90[f]

[a]100–129 mg/dL LDL indicates a near or above optimal level. <70 mg/dL is a desirable goal for very-high-risk persons.
[b]≥190 mg/dL LDL indicates a very high risk.
[c]≥500 mg/dL triglycerides indicates a very high risk.
[d]Body mass index (BMI) was defined in Chapter 8; BMI standards are found on the inside back cover of this text.
[e]These values indicate prehypertension.
[f]These values indicate stage one hypertension; ≥160/≥100 indicates stage two hypertension. Physicians use these classifications to determine medical treatment..

HOW TO Assess a Person's Risk of Heart Disease

This assessment estimates a person's 10-year risk for developing a major coronary event associated with CHD, such as a heart attack.[a] A high score does not mean that the person *will* develop a heart attack, but it warns of the possibility and suggests the need to consult a physician. To use this diagram, you need to know a person's age, total and HDL cholesterol levels, and blood pressure.

Age (years):

	Men	Women
20–34	−9	−7
35–39	−4	−3
40–44	0	0
45–49	3	3
50–54	6	6
55–59	8	8
60–64	10	10
65–69	11	12
70–74	12	14
75–79	13	16

HDL (mg/dL):

	Men	Women
≥60	−1	−1
50–59	0	0
40–49	1	1
<40	2	2

Systolic Blood Pressure (mm Hg):

	Untreated		Treated	
	Men	Women	Men	Women
<120	0	0	0	0
120–129	0	1	1	3
130–139	1	2	2	4
140–159	1	3	2	5
≥160	2	4	3	6

Total Cholesterol (mg/dL):

	Age 20–39		Age 40–49		Age 50–59		Age 60–69		Age 70–79	
	Men	Women	Men	Women	Men	Women	Men	Women	Men	Women
<160	0	0	0	0	0	0	0	0	0	0
160–199	4	4	3	3	2	2	1	1	0	1
200–239	7	8	5	6	3	4	1	2	0	1
240–279	9	11	6	8	4	5	2	3	1	2
≥280	11	13	8	10	5	7	3	4	1	2

Smoking (any cigarette smoking in the past month):

Smoker	8	9	5	7	3	4	1	2	1	1
Nonsmoker	0	0	0	0	0	0	0	0	0	0

Scoring Heart Disease Risk

Add up the total points: _____ . Using the table at the right, find the total in the first column for the appropriate gender, and then check the second column to learn the percentage risk of developing severe CHD within the next 10 years. The LDL goals and treatment options for people at high risk (more than 20 percent), moderate risk (10 to 20 percent), and low risk (less than 10 percent) are shown in the "How to" on p. 848.

Men		Women	
Total	Risk(%)	Total	Risk(%)
<0	<1	<9	<1
0–4	1	9–12	1
5–6	2	13–14	2
7	3	15	3
8	4	16	4
9	5	17	5
10	6	18	6
11	8	19	8
12	10	20	11
13	12	21	14
14	16	22	17
15	20	23	22
16	25	24	27
≥17	≥30	≥25	≥30

[a]An electronic version of this assessment is available on the ATP III page of the National Heart, Lung, and Blood Institute's website (www.nhlbi.nih.gov/guidelines/cholesterol). Another risk inventory is available from the American Heart Association (www.americanheart.org).

SOURCE: Adapted from Expert Panel on Detection, Evaluation, and Treatment of High Blood Cholesterol in Adults (Adult Treatment Panel III), *Third Report of the National Cholesterol Education Program (NCEP)*, NIH publication no. 02-5216 (Bethesda, Md.: National Heart, Lung, and Blood Institute, 2002), section III.

Therapeutic Lifestyle Changes for Lowering CHD Risk

People who have CHD or multiple risk factors for CHD are often advised to make dietary and lifestyle changes before considering drug treatment. An approach to risk reduction promoted by the National Cholesterol Education Program, known

HOW TO Detect, Evaluate, and Treat High Blood Cholesterol

The most recent National Cholesterol Education Program report, Adult Treatment Panel III (ATP III), identifies three categories of risk that affect treatment for LDL cholesterol, based on easily identified risk factors. By using this nine-step risk assessment, a person's risk for an acute coronary event over the next 10 years can be identified as being less than 10 percent (low risk), 10 to 20 percent (moderate risk), or over 20 percent (high risk). In addition, treatment goals are set for each risk category. Note that these are guidelines only and should not override the judgment of an attending physician.

Step 1. Obtain a complete lipoprotein profile from blood samples taken after a 9- to 12-hour fast. (Desirable blood lipid levels are shown in Table 27-2.)

Step 2. Identify the presence of diseases that confer high risk for acute CHD events; such conditions are considered CHD risk equivalents and include:

- Symptoms of CHD.
- Symptoms of stroke.
- Aortic aneurysm.
- Intermittent claudication.
- Diabetes mellitus.

Step 3. Identify major risk factors other than LDL cholesterol:

- Cigarette smoking.
- Hypertension (blood pressure ≥140/≥90 mm Hg) or use of an antihypertensive medication.
- Low HDL cholesterol (<40 mg/dL). If HDL cholesterol is ≥60 mg/dL, substract one risk factor from the total count.
- Family history of premature CHD (CHD in father or brother at younger than 55 years; mother or sister at younger than 65 years).
- Age (if male, 45 years or older; if female, 55 years or older).

Step 4. Assess 10-year CHD risk: high risk (more than 20 percent), moderate risk (10 to 20 percent), and low risk (less than 10 percent).

- If a CHD risk equivalent is present (see Step 2), the person is automatically at high risk (more than 20 percent within next 10 years) of an acute coronary event.
- If two or more risk factors (other than LDL) are present (see Step 3), assess 10-year risk according to age, total cholesterol, HDL cholesterol, systolic blood pressure, and smoking habit (see the "How to" on p. 847).
- If one risk factor (or less) is present, a person's 10-year risk is ≤10 percent.

Step 5. Determine LDL goals and treatment options for each risk category:

Risk Category	LDL Goal	LDL Level at Which to Start Therapeutic Lifestyle Changes (TLC)	LDL Level at Which to Consider Drug Therapy
High	<100 mg/dL[a]	≥100 mg/dL	≥130 mg/dL[b]
Moderate	<130 mg/dL[c]	≥130 mg/dL	≥130 mg/dL[b] if 10-year risk 10–20% ≥160 mg/dL if 10-year risk <10%
Low	<160 mg/dL	≥160 mg/dL	≥190 mg/dL

[a]<70 mg/dL is a goal for very-high-risk patients.
[b]Drug therapy is sometimes considered for LDL >100 mg/dL.
[c]<100 mg/dL is a goal for some patients.

as Therapeutic Lifestyle Changes (TLC), is summarized in Table 27-3.[28] The main features of the TLC plan include a cholesterol-lowering diet, weight reduction, and regular physical activity. If the TLC recommendations are followed carefully, substantial progress may be seen after six weeks. People with a high risk of CHD should try to lower LDL cholesterol with at least a three-month trial of TLC before starting drug therapy. This section describes the elements of the TLC plan in detail.

Saturated Fat Of the dietary lipids, saturated fat has the strongest effect on blood cholesterol levels, and replacing saturated fat with monounsaturated and polyunsaturated fats can generally lower LDL levels. Clinical trials have suggested that LDL cholesterol rises about 2 percent for every 1 percent increase in kcalories from saturated fat.[29] The TLC recommendation is to consume less than 7 percent of total kcalories as saturated fat. Currently, the saturated fat intake in the United States averages about 11 percent of total kcalories consumed.[30]

For most people, cutting down on saturated fat involves more than just switching from butter to vegetable oil, as the main sources of saturated fat in the United States are whole-milk products, high-fat meats, and baked goods. Choosing lean meats or fish, using fat-free or low-fat milk products, and avoiding certain types of bakery products are usually more effective ways of reducing saturated fat. Chapter 5 and Highlight 5 provide additional information about food selections that are low in saturated fat.

Replacing saturated fat with carbohydrate can also lower LDL cholesterol, but such a change may also lower HDL cholesterol and raise blood triglyceride levels. ◆ This effect may be offset somewhat by limiting added sugars and including fiber-rich foods; ideally, the diet should include generous amounts of whole grains, legumes, fruits, and vegetables. The TLC diet recommends a carbohydrate intake in the range of 50 to 60 percent of total kcalories.

◆ Diets high in carbohydrate—especially those high in added sugars—can raise blood triglyceride levels in some people.

Step 6. Initiate Therapeutic Lifestyle Changes (TLC) if the patient's LDL level is above the goal. The main features of TLC include (see the text for details):

- Restricted intake of saturated fat (less than 7 percent of total kcalories) and cholesterol (less than 200 milligrams per day).
- Increased intake of soluble fiber (10–25 grams per day) and plant stanols and sterols (2 grams per day).
- Moderate physical activity (approximately 200 kcalories expended per day).
- Weight reduction, if necessary.

If there is no improvement in LDL after three months, consider drug therapy.

Step 7. Consider adding drug therapy if LDL levels exceed recommendations shown in Step 5. Continue lifestyle changes. Major drugs used for cholesterol lowering include:

- *Statins (include lovastatin, pravastatin):* Reduce cholesterol synthesis in the liver. They reduce LDL and triglycerides and increase HDL.
- *Bile acid sequestrants (include cholestyramine, colestipol):* Bind bile acids in the small intestine, reducing reabsorption. They reduce LDL and raise HDL slightly.
- *Nicotinic acid (a form of niacin):* Reduces triglyceride breakdown in adipose tissue and subsequent VLDL and LDL production. It reduces triglycerides and LDL and raises HDL.
- *Fibric acids (include gemfibrozil, clofibrate):* Affect the production of proteins that help regulate lipoprotein synthesis and breakdown. They reduce triglycerides and raise HDL.

Step 8. Identify metabolic syndrome on the basis of the presence of three or more of the following risk determinants:

- Abdominal obesity (waist measurement of more than 40 inches in men or more than 35 inches in women).
- Elevated triglycerides (≥150 mg/dL).
- Low HDL cholesterol (<40 mg/dL in men or <50 mg/dL in women).
- Elevated blood pressure (≥130/≥85 mm Hg).
- Elevated fasting glucose (≥100 mg/dL).

If metabolic syndrome is present, treatment should begin with weight management and moderate physical activity. Aspirin should be recommended for CHD patients. If there is no improvement, elevated blood pressure and dyslipidemias should be actively treated.

Step 9. In general, elevated triglyceride levels (≥150 mg/dL) are treated with weight management and moderate physical activity.

- If they remain above 200 mg/dL, drug therapy should be considered (nicotinic acid and fibric acids).
- If they are above 500 mg/dL, a very-low-fat diet (no more than 15 percent kcalories from fat) may be prescribed to prevent complications.

TABLE 27-3 Reducing Risk of CHD with Therapeutic Lifestyle Changes

Dietary Strategies

- Limit saturated fat to less than 7 percent of total kcalories and cholesterol to less than 200 milligrams per day. Maintaining a fat intake that is 25 to 35 percent of total kcalories may help with this goal.
- Replace saturated fats with carbohydrates from whole grains, legumes, fruits, and vegetables or with unsaturated fats from fish, vegetable oils, and nuts.
- Avoid food products that contain *trans*-fatty acids. The *trans* fat content in packaged foods is shown on the Nutrition Facts panel of food labels.
- Choose foods high in soluble fibers, including oats, barley, beans, and fruit. Psyllium seed husks can be used as a food supplement to help lower LDL cholesterol levels.
- Regularly consume food products that contain added plant sterols or stanols.
- To reduce blood pressure, choose a diet that is high in fruits and vegetables, low-fat milk products, nuts, and whole grains. Limit sodium intake to 2400 milligrams per day.[a]
- Fish can be consumed regularly as part of a CHD risk–reduction diet.
- If alcohol is consumed, it should be limited to one drink daily for women and two drinks daily for men.

Lifestyle Choices

- Physical activity: At least 30 minutes of moderate-intensity endurance activity should be undertaken on most days of the week. The eventual goal should be an expenditure of at least 2000 kcalories weekly.
- Smoking cessation: Exposure to any form of tobacco smoke should be minimized.

Weight Reduction

- Weight reduction may improve other CHD risk factors. The general goal of a weight-management program should be to prevent weight gain, reduce body weight, and maintain a lower body weight over the long term. The initial goal of a weight-loss program should be to lose no more than 10 percent of original body weight.

[a]According to DRI recommendations, sodium intake should be limited to 2300 milligrams daily.

Polyunsaturated and Monounsaturated Fat As described in the previous section, replacing saturated fat with either monounsaturated or polyunsaturated fat helps to lower LDL levels. A switch to polyunsaturated fat tends to have the greater effect, but it also promotes a slight reduction in HDL cholesterol.[31] Other concerns are that high intakes of polyunsaturated fat may contribute to oxidative stress ◆ or increase inflammation within the body. ◆ Therefore, TLC guidelines limit polyunsaturated fat to 10 percent of total kcalories, whereas up to 20 percent of kcalories from monounsaturated fat are allowed. Keep in mind that most polyunsaturated fat in the diet consists of omega-6 fatty acids, such as linoleic acid; omega-3 fatty acids may have beneficial effects on heart disease risk, as described in a later section.

◆ Reminder: Polyunsaturated fats are more susceptible to oxidation than saturated fats, although the clinical significance of consuming high amounts is still unknown.

◆ Reminder: Polyunsaturated fatty acids are precursors for the eicosanoids, which mediate inflammation (see p. 711).

Total Fat For people whose fat intake includes substantial saturated fat, limiting total fat may indirectly reduce saturated fat. Therefore, the TLC recommendation for total fat is an intake of 25 to 35 percent of kcalories. People with the metabolic syndrome, who typically have elevated blood triglycerides, may benefit from a fat intake at the upper end of this range (30 to 35 percent) so that their carbohydrate intakes are not excessive. Fat intakes higher than 35 percent of kcalories are discouraged because they may promote weight gain in some people.

Dietary Cholesterol A high cholesterol intake can raise LDL levels, and reducing dietary cholesterol lowers LDL cholesterol in most people. The TLC recommendation is a cholesterol intake of less than 200 milligrams per day. Currently, the daily cholesterol intake in the United States averages about 273 milligrams, although it is higher in men (347 milligrams) than in women (235 milligrams).[32] Eggs contribute about one-third of the cholesterol in the American diet, followed by meats, milk, and cheese.

***Trans* Fat** *Trans*-fatty acids raise LDL cholesterol levels, and when they replace saturated fats in the diet (as when stick margarine replaces butter), they may also cause a decline in HDL cholesterol. *Trans* fats may also raise CHD risk by altering blood vessel function, promoting inflammation, and reducing LDL size.[33] The TLC recommendation is to keep *trans* fat intake as low as possible.

Most sources of *trans* fats are foods made with partially hydrogenated vegetable oils; examples include baked goods such as crackers, cookies, and doughnuts; snack foods such as potato chips and corn chips; and fried foods such as French fries and fried chicken. In the past few years, many food manufacturers have been reducing their use of hydrogenated oils and reformulating products so that they contain minimal amounts of *trans* fats. Thus, margarine, vegetable shortening, and many baked goods are now available with little or no *trans* fat.

Soluble Fibers As Chapter 4 explained, a diet rich in soluble, viscous fibers can reduce LDL cholesterol levels by inhibiting cholesterol and bile absorption in the small intestine and reducing cholesterol synthesis in the liver (see p. 122). An extra 5 to 10 grams of soluble fiber daily is associated with a 5 percent reduction in LDL cholesterol. Dietary sources of soluble fibers include oats, barley, legumes, and fruits. The soluble fiber from psyllium seed husks, frequently used to treat constipation, is effective for lowering cholesterol levels when used as a dietary supplement.

Plant Sterols and Stanols Foods or supplements that contain significant amounts of plant sterols or plant stanols can help to lower LDL cholesterol levels. ◆ Plant sterols and stanols are added to various food products, such as margarine or cheese, or supplied in dietary supplements. These plant compounds work by interfering with cholesterol and bile absorption. Clinical trials have shown that a bit more than 1 tablespoon of margarine daily (containing about 2 grams of plant sterols) can lower LDL cholesterol by up to 15 percent without lowering HDL cholesterol.[34]

◆ Plant sterols are extracted from soybeans and pine tree oils, and they are then hydrogenated to produce the plant stanols that are added to commercial products.

Sodium and Potassium Intakes Excessive sodium in the diet can raise blood pressure, ◆ whereas potassium can lower blood pressure. A low-sodium diet that contains generous amounts of fruits and vegetables, low-fat milk products, nuts,

◆ Some people are more sensitive to sodium intakes than others, as discussed in a later section (pp. 858–859)

and whole grains has been found to substantially reduce blood pressure, largely due to the diet's content of potassium and several other minerals that have blood pressure–lowering effects. This diet (the *DASH Eating Plan*) and other factors that influence blood pressure are discussed in a later section (see pp. 858–860).

Fish and Omega-3 Fatty Acids The omega-3 fatty acids in fish, known as EPA and DHA, ◆ may benefit people who have had a heart attack by suppressing inflammation, reducing blood clotting, stabilizing heart rhythm, and lowering triglyceride levels. In addition, including fish in the diet can reduce CHD risk because fish is low in saturated fat and often replaces entrées that contain animal fats. The American Heart Association recommends consuming two servings of fish per week, with an emphasis on fatty fish.[35] Fish oil supplements (providing 1 gram of EPA and DHA daily) may be helpful for individuals with documented CHD, and they are particularly useful for treating individuals with elevated triglyceride levels (see p. 854).[36] Chapter 5 provides additional information about the omega-3 fatty acids and fish oil supplements.

The 18-carbon omega-3 fatty acids found in flaxseed and other land plants have lesser or different effects than the omega-3 fatty acids from marine sources. Although some evidence suggests that moderate increases in these plant sources of omega-3 fatty acids may improve CHD risk, additional research is needed to confirm their benefits.[37]

Alcohol Moderate consumption of alcohol—from beer, wine, or liquor—has favorable effects on HDL cholesterol levels, atherosclerosis, inflammation, blood-clotting activity, and insulin resistance.[38] Alcohol use is also inversely related to the incidence of heart attack. These benefits are most apparent in men and women who are at least 45 and 55 years old, respectively. Of note, only low or moderate amounts of alcohol—no more than one drink daily for women and two for men—have been found to lower CHD risk, and higher intakes are associated with higher mortality rates. One "drink" is equivalent to 12 ounces of beer, 5 ounces of wine, 10 ounces of wine cooler, or $1^1/_2$ ounces of 80 proof distilled spirits such as gin, rum, vodka, and whiskey.

For some people, alcohol's negative effects can offset any health advantages. Alcohol consumption is associated with cancers of the gastrointestinal (GI) tract and several other cancers, including liver cancer and breast cancer.[39] Alcohol is destructive to the liver and male reproductive system, and high alcohol intakes can elevate blood pressure and triglyceride levels. Moreover, up to 10 percent of adults misuse alcohol.[40] For these reasons, nondrinkers are not encouraged to start drinking in an effort to decrease their risk for CHD.

Regular Physical Activity Regular aerobic activity reverses a number of risk factors for CHD: it can lower triglycerides, raise HDL, lower blood pressure, promote weight loss, improve insulin sensitivity, strengthen heart muscle, and increase coronary artery size and tone. ◆ Aerobic activities that use large muscle groups have the greatest benefits; such activities include brisk walking, running, swimming, cycling, stair-stepping, and cross-country skiing. Alternatives for busy people include heavy house cleaning, lawn mowing, raking leaves, and walking to and from work.

Research studies have found that the most active persons have CHD rates that are about half the rates of those who are the least active.[41] The American Heart Association recommends that all adults participate in at least 30 minutes of moderate-intensity physical activity on most days of the week, whereas 60 minutes of physical activity is suggested for adults who are attempting or maintaining weight loss.[42] If preferred, physical activity can be divided into several sessions during the day. Note that vigorous activity increases the risk of heart attack and sudden death in individuals with diagnosed heart disease, so sedentary adults are advised to increase their activity levels gradually.[43]

Smoking Cessation Cigarette smoking is a major risk factor for CHD, as well as for other types of cardiovascular disease. ◆ Compounds in smoke damage blood vessel cells, cause chronic inflammation, decrease the oxygen-carrying capacity of

© Ronnie Kaufman/Corbis

Regular aerobic exercise can strengthen the cardiovascular system, promote weight loss, reduce blood pressure, and improve blood glucose and lipid levels.

◆ Reminder: *EPA* and *DHA* are abbreviations for eicosapentaenoic acid and docosahexaenoic acid, respectively, the 20- and 22-carbon polyunsaturated fatty acids found in fish. See pp. 154 and 174 for a review of these fatty acids.

◆ Resistance exercise can also help to reverse some CHD risk factors, but its overall effect on CHD risk is uncertain.

◆ Cigar and pipe smoking can also increase the risk of CHD, but the risk may be lower because the smoke is less likely to be inhaled.

the blood (contributing to ischemia), promote vasoconstriction and blood coagulation, and raise heart rate and blood pressure.[44] Smokers also tend to have higher levels of LDL and lower HDL. Secondhand smoke can cause these effects as well.

The risk from smoking depends on the amount and duration of exposure: it is related to the age when smoking started, the number of cigarettes smoked daily, and the degree of inhalation. Even one or two cigarettes daily increase CHD risk, and cigarettes that have low tar and nicotine do not lower the risk. Quitting smoking improves CHD risk quickly; the incidence of CHD drops to levels near those of nonsmokers in just 2 years.[45] Currently, about 26 percent of men and 21 percent of women in the United States are cigarette smokers.[46]

Weight Reduction Obesity, especially abdominal obesity, is considered to be an independent risk factor for CHD.[47] In obesity, the enlarged adipose cells become more active, increasing their synthesis and release of inflammatory mediators and blood-clotting factors; these changes raise the risks of both atherosclerosis and heart attack. Obesity also strains the heart and blood vessels by increasing total blood volume, **cardiac output,** and the workload of the left ventricle (which pumps blood to the major arteries).[48] Several metabolic changes that accompany obesity increase CHD risk as well; these include insulin resistance, hypertension, elevated triglycerides, low HDL levels, and a reduction in LDL size. ◆

◆ The pattern of metabolic complications associated with obesity characterizes the metabolic syndrome, which was described fully in Highlight 26.

Weight reduction can improve such CHD risk factors as high blood pressure, elevated blood triglycerides, low HDL cholesterol, and insulin resistance. However, individuals should focus on weight reduction only *after* they have adopted other dietary measures to lower LDL.[49] This approach ensures that LDL reduction is given priority and that the individual does not receive a multitude of dietary suggestions at one time. The initial goal of a weight-loss program should be no more than 10 percent of a person's original body weight. For some, avoiding additional weight gain may be a desirable starting point.

Successful Adherence to Lifestyle Changes Incorporating many lifestyle changes at once can be difficult, and instruction and counseling are critical for success. Health practitioners can help to motivate patients by explaining the reasons for each change, setting obtainable goals, and providing practical suggestions. An initial diet history can offer clues about a person's behaviors and preferences, and follow-up visits allow an opportunity to determine compliance. In some individuals, high LDL cholesterol levels may persist despite adherence to a TLC program; drug therapy may be the only effective treatment for such people. Review Table 27-3 (p. 849) for a summary of the Therapeutic Lifestyle Changes discussed in this section. The "How to" on p. 853 offers suggestions for implementing a heart-healthy diet.

Lifestyle Changes for Hypertriglyceridemia

◆ Blood triglycerides:
- Borderline high: 150–199 mg/dL
- High: 200–499 mg/dL
- Very high: ≥500 mg/dL

Hypertriglyceridemia (elevated blood triglycerides) ◆ is common in people with diabetes mellitus and the metabolic syndrome and may also result from other disorders. Severe hypertriglyceridemia can cause serious complications, including fatty deposits in the liver and skin and acute pancreatitis.[50] Whereas diet and lifestyle contribute to mild hypertriglyceridemia (borderline-high triglyceride levels), genetic factors are usually responsible for severe cases (high and very high triglyceride levels).

Mild Hypertriglyceridemia Dietary and lifestyle changes can improve mild hypertriglyceridemia.[51] Overweight and obesity, a sedentary lifestyle, and cigarette smoking all may raise triglyceride levels. Dietary factors that can increase triglyceride levels include a high alcohol intake or high intake of carbohydrate (60 percent or more of total kcalories); sucrose and fructose are the carbohydrates that have the strongest effects. Thus controlling body weight, being physically active, quitting smoking, restricting alcohol, and avoiding a high-carbohydrate intake (especially of sugars) are basic treatments for hypertriglyceridemia. As mentioned

cardiac output: the volume of blood pumped by the heart within a specified period of time.

HOW TO Implement a Heart-Healthy Diet

Following a heart-healthy diet can require major changes in dietary choices. Patients may find it easier to adopt a new diet if only a few changes are made at a time. Discussing positive choices (what to eat) first, rather than negative ones (what not to eat), may also aid compliance. These suggestions can help patients implement their diet.

Breads, Cereals, and Pasta

- Choose whole-grain breads and cereals. Make sure the first ingredient on bread and cereal labels is "whole wheat" rather than "enriched wheat flour."
- Bakery products often contain *trans*-fatty acids. Choose foods whose labels *do not* list any *trans* fat in the Nutrition Facts panel or "hydrogenated oil" in the ingredients list. Crackers, chips, cookies, and doughnuts often include *trans* fats.
- Avoid products that contain tropical oils (coconut, palm, and palm kernel oil), which are high in saturated fat.

Fruits and Vegetables

- Consume fruits and vegetables frequently. Keeping the refrigerator stocked with a variety of colorful fruits and vegetables (baby carrots, grapes, blueberries, melon) makes it easier to choose healthful foods when the urge to nibble arises.
- Incorporate at least one or two servings of fruits and vegetables into each meal. People who rarely eat fruits or vegetables may start by adding at least one of their favorites to each meal.
- Choose canned products carefully. Canned vegetables (especially tomato-based products) may be high in sodium. Fruits that are canned in juice are higher in nutrient density than those canned in syrup.
- Restrict high-sodium foods such as pickles, olives, sauerkraut, and kimchee.
- Avoid French fries from fast-food restaurants, which are often loaded with *trans* fats.

Lunch and Dinner Entrées

- Limit meat, fish, and poultry servings to a maximum intake of 5 ounces per day.
- Select lean cuts of beef, such as sirloin tip, round steak, and arm roast, and lean cuts of pork, such as center-cut ham, loin chops, and tenderloin. Trim visible fat before cooking.
- Select extra-lean ground meat, and drain it well after cooking. Use lean ground turkey, without skin added, in place of ground beef.
- Limit cholesterol-rich organ meats (liver, brain, sweetbreads) and shrimp.
- Limit egg yolks to no more than two per week because the yolks are high in cholesterol (about 215 milligrams per yolk). Replace whole eggs in recipes with egg whites or commercial egg substitutes or similar reduced-cholesterol products.
- Include more vegetarian entrées or legume dishes to boost soluble fiber and lower saturated fat intakes. Pasta and stir-fry recipes can help to reduce meat intake and increase vegetables in the diet.
- Restrict these high-sodium foods:
  - Cured or smoked meats such as beef jerky, bologna, corned or chipped beef, frankfurters, ham, luncheon meats, salt pork, and sausage.
  - Salty or smoked fish, such as anchovies, caviar, salted or dried cod, herring, sardines, and smoked salmon.
  - Packaged, canned, or frozen soups, sauces, and entrées.

Milk Products

- Milk products can be good sources of protein, calcium, vitamin D, and potassium. To obtain two to three servings daily, include a portion of fat-free or low-fat milk, yogurt, or cottage cheese in each meal.
- Use yogurt or fat-free sour cream to make dips or salad dressings. Substitute evaporated fat-free milk for heavy cream.
- Restrict foods high in saturated fat or sodium, such as cheese, processed cheeses, ice cream, and many other milk-based desserts.

Fats and Oils

- Add nuts (not salted) and avocados to meals to increase monounsaturated fat intakes and make meals more appetizing.
- Include vegetable oils in salad dressings and recipes; these include canola, corn, olive, peanut, safflower, sesame, soybean, and sunflower oils.
- Use margarines with added plant sterols or stanols regularly to lower LDL cholesterol levels.
- Select soft margarines in tubs or liquid form; they are low in *trans* fats. Avoid stick margarines and solid vegetable shortenings.
- Avoid products that contain tropical oils (coconut, palm, and palm kernel oil), which are high in saturated fat.

Spices and Seasonings

- Use salt only at the end of cooking, and you will need to add much less. Use salt substitutes at the table.
- Spices and herbs improve the flavor of foods without adding sodium. Try using more garlic, ginger, basil, curry or chili powder, cumin, pepper, lemon, mint, oregano, rosemary, and thyme.
- Check the sodium content on labels. Flavorings and sauces that are usually high in sodium include bouillon cubes, soy sauce, steak and barbecue sauces, relishes, mustard, and catsup.

Snacks and Desserts

- Select low-sodium and low-saturated-fat choices such as unsalted pretzels and nuts, plain popcorn, and unsalted chips and crackers.
- Choose canned or dried fruits and some raw vegetables to boost fruit and vegetable intake.
- Enjoy angel food cake, which is made without egg yolks or added fat.
- Select low-fat frozen desserts such as sherbet, sorbet, fruit bars, and some low-fat ice creams.

earlier, high triglyceride levels are often associated with low HDL, and the lifestyle changes listed here are likely to improve HDL levels as well.

Severe Hypertriglyceridemia Medications are usually necessary for treating severe hypertriglyceridemia. Weight reduction and physical activity are still emphasized, and a very-low-fat diet, providing less than 15 percent of kcalories from fat, may be required in extreme cases to prevent dangerous complications.[52] If the dietary fat restriction is severe, medium-chain triglycerides (see p. 664 and p. 761) can be useful for replacing fats and oils in the diet.

Fish Oil Supplements and Hypertriglyceridemia Fish oil supplements are sometimes recommended for treating hypertriglyceridemia. Clinical trials have shown that a daily intake of 2 to 4 grams of EPA and DHA (combined) can lower triglyceride levels by 30 to 50 percent.[53] Fish oil therapy should be monitored by a physician due to the potential for adverse effects.[54] Although over-the-counter supplements are available, most provide only small amounts of EPA/DHA (about 300 milligrams per capsule), requiring the use of 7 to 13 capsules daily. A prescription form of fish oil (Lovaza) is available and contains about 840 milligrams of EPA/DHA per capsule.

Vitamin Supplementation and CHD Risk

People often ask about the potential benefits of using certain types of vitamin supplements for reducing CHD risk, particularly B vitamin and antioxidant supplements. Most clinical trials have not been able to confirm any benefits from using these supplements, as described in this section.

B Vitamin Supplements and Homocysteine As mentioned earlier, elevated blood homocysteine levels are a known risk factor for CHD, but whether homocysteine itself is directly damaging or is simply an indicator of other abnormalities remains unknown. Possibly, homocysteine has harmful effects on the artery wall, causes oxidative stress, or heightens blood-clotting activity that worsens atherosclerosis.[55] Although increased intakes of folate, vitamin B_6, and vitamin B_{12} can lower homocysteine levels, clinical research trials have not demonstrated that B vitamin supplements can reduce the incidence of heart attacks in those at risk.[56] Hence, B vitamin supplementation is not currently recommended for patients at risk for CHD.

Antioxidant Vitamin Supplements Because oxidized LDL promote atherosclerosis, researchers have hypothesized that antioxidant supplementation may help to prevent atherosclerosis and reduce CHD risk. Several epidemiological studies have suggested that antioxidant-rich diets may protect against CHD, but because persons who consume such diets usually maintain a healthy lifestyle and body weight as well, it has been difficult to determine whether the antioxidants are responsible for the effect. Most studies that tested supplementation with single antioxidants (such as vitamins C or E), combinations of antioxidants, or multivitamins have produced weak or inconsistent results,[57] and several studies suggested possible harm.[58] Until more data are available, there is no recommendation to use antioxidant supplements for heart disease prevention.[59]

Drug Therapies for CHD Prevention

Physicians usually recommend a trial of dietary and lifestyle changes before considering drug therapies for CHD prevention. If an individual cannot reach LDL goals with lifestyle changes alone, one or more medications may be prescribed (review Step 7 in the "How to" on pp. 848–849). For lowering LDL levels, statins are the most effective drugs.* Bile acid sequestrants can also lower LDL levels, but their side effects (constipation and intestinal gas) may cause difficulty with compliance. For lowering triglyceride levels and increasing HDL, both fibric acids (fibrates) and nicotinic acid are effective; nicotinic acid can also reduce LDL and lipoprotein(a) levels. Individuals using medications for CHD prevention should continue the TLC program so that they can use the lowest possible doses of the drugs.[60]

In addition to lipid-lowering medications, some people may benefit from drugs that suppress blood clotting (anticoagulants and aspirin) or reduce blood pressure. Nitroglycerin may be given to alleviate angina as needed. Some medications

*The drug *ezetimibe* is also effective for lowering blood cholesterol levels, but clinical trials have not shown that the drug can prevent atherosclerosis progression or reduce the incidence of heart attack or stroke.

DIET-DRUG INTERACTIONS

Check this table for notable nutrition-related effects of the medications discussed in this chapter.

	Gastrointestinal Effects	Interactions with Dietary Substances	Metabolic Effects
Anticoagulants (warfarin)	—	Requires consistent vitamin K intake to maintain effectiveness. Enhanced drug effects with supplementation of vitamin E, dong quai, danshen, fish oils, garlic, and ginkgo. Reduced drug effects with coenzyme Q, ginseng, and green tea. Avoid alcohol.	—
Antihypertensives			
Beta-blockers			Elevated serum potassium levels, hypoglycemia.
Calcium channel blockers	Nausea, constipation.	Avoid herbal supplements that contain natural licorice. Avoid grapefruit juice, which may enhance drug effects.	
ACE inhibitors	Reduced taste sensation.	Avoid herbal supplements that contain natural licorice. Avoid potassium supplements and salt substitutes containing potassium.	Elevated serum potassium levels.
Antilipimics			
Statins	Constipation, flatulence, GI discomfort.	Avoid grapefruit juice, which may enhance drug effects.	Elevated serum liver enzymes.
Bile acid sequestrants	Flatulence, diarrhea, constipation.	Cause reduced absorption of fat-soluble vitamins.	Electrolyte imbalances, iron deficiency.
Nicotinic acid	GI discomfort.	Avoid alcoholic beverages, coffee, and tea, which may increase side effects.	Elevated serum liver enzymes and uric acid levels, hyperglycemia, low blood pressure.
Digoxin	Anorexia, nausea, stomach cramps, diarrhea.	High-fiber foods and magnesium supplements can reduce drug absorption. St. John's wort may reduce drug efficacy.	Elevated serum potassium and reduced serum magnesium levels. Drug toxicity can develop if body potassium levels are low.
Diuretics (furosemide, spironolactone[a])	Dry mouth, anorexia, decreased taste perception.	Furosemide bioavailability is reduced when the drug is taken with food.	Fluid and electrolyte imbalances,[a] hyperglycemia (spironolactone), hyperlipidemia (spironolactone), thiamin and zinc deficiencies.
Nitroglycerin	Decreased taste perception.	Increases effects of alcohol.	

[a] *Furosemide* is a "potassium-wasting" diuretic; patients should increase intakes of potassium-rich foods. *Spironolactone* is a "potassium-sparing" diuretic; patients should avoid supplemental potassium and potassium-containing salt substitutes.

may affect nutrition status or food intake (see the Diet-Drug Interactions feature); the interactions can be even more complicated when multiple medications are used.

Treatment of Heart Attack

As explained earlier, a heart attack occurs when a blood clot blocks a coronary artery and cuts off the supply of blood and oxygen to heart muscle. If the blood flow within the artery is restored quickly, the heart muscle may be saved; if not, the

muscle tissue dies. Drug therapies given immediately after a heart attack may include thrombolytic drugs (clot-busting drugs), anticoagulants, aspirin, painkillers, and medications that regulate heart rhythm and reduce blood pressure.[61] Patients are not given food or beverages, except for sips of water or clear liquids, until their condition stabilizes. Once able to eat, they are initially offered small portions of foods that are low in sodium, saturated fat, and cholesterol. The sodium restriction helps to limit fluid retention but may be lifted after several days if the patient shows no signs of heart failure.

A heart attack patient needs to regain strength and learn strategies that can reduce the risk of a future heart attack; such strategies are similar to the Therapeutic Lifestyle Changes (TLC) described earlier. Thus, the cardiac rehabilitation programs in hospitals and outpatient clinics include exercise therapy, instruction about a heart-healthy diet and smoking cessation, and medication counseling. The programs often last several months. Home-based rehabilitation programs are also beneficial, but they are more limited in scope and lack the benefit of group interaction.

IN SUMMARY

Long-term CHD management emphasizes risk reduction. Modifiable risk factors include elevated LDL and triglyceride levels, high blood pressure, cigarette smoking, diabetes, obesity, a sedentary lifestyle, and various dietary factors. To help in reducing LDL levels and eliminating other risk factors, the Therapeutic Lifestyle Changes (TLC) approach is suggested. Dietary recommendations are to reduce saturated fat, *trans* fats, and cholesterol; increase soluble fiber; and incorporate plant sterols and stanols into the diet. Other recommendations include regular physical activity, smoking cessation, and weight reduction. Treatment for mild hypertriglyceridemia emphasizes weight control, regular physical activity, smoking cessation, avoiding a high carbohydrate intake, and restricting alcohol. Severe hypertriglyceridemia requires drug therapies and dietary fat restriction. Medications given after a heart attack suppress blood clotting, regulate heart rhythm, and reduce blood pressure, and patients are offered small portions of heart-healthy foods. To reduce the risk of a future heart attack, patients must learn strategies similar to the TLC approach.

Hypertension

Hypertension (high blood pressure) affects nearly one-third of adults in the United States.[62] Prevalence is especially high among African Americans, who develop hypertension earlier in life and sustain higher average blood pressures throughout their lives than other ethnic groups. An estimated 28 percent of people with hypertension are unaware that they have it.[63] ◆

◆ Blood pressure is measured both when heart muscle contracts (*systolic* blood pressure) and when it relaxes (*diastolic* blood pressure). Measurements are expressed as millimeters of mercury (mm Hg).

	Systolic	Diastolic
• Desirable blood pressure	<120	<80
• Prehypertension	120–139	80–89
• Hypertension	≥140	≥90

Although people cannot feel the physical effects of hypertension, it is a primary risk factor for atherosclerosis and cardiovascular diseases. For each 20/10 mm Hg increase above normal blood pressure (that is, an increase of 20 mm Hg in systolic blood pressure and 10 mm Hg in diastolic blood pressure), the risk of death from CVD doubles.[64] Elevated blood pressure forces the heart to work harder to eject blood into the arteries; this effort weakens heart muscle and increases the risk of developing heart arrhythmias, heart failure, and even sudden death. Hypertension is also a primary cause of stroke and kidney failure. Reducing blood pressure can dramatically reduce the incidence of these diseases.

Factors That Influence Blood Pressure

Although the underlying causes of most cases of hypertension are not fully understood, much is known about the physiological factors that affect blood pressure,

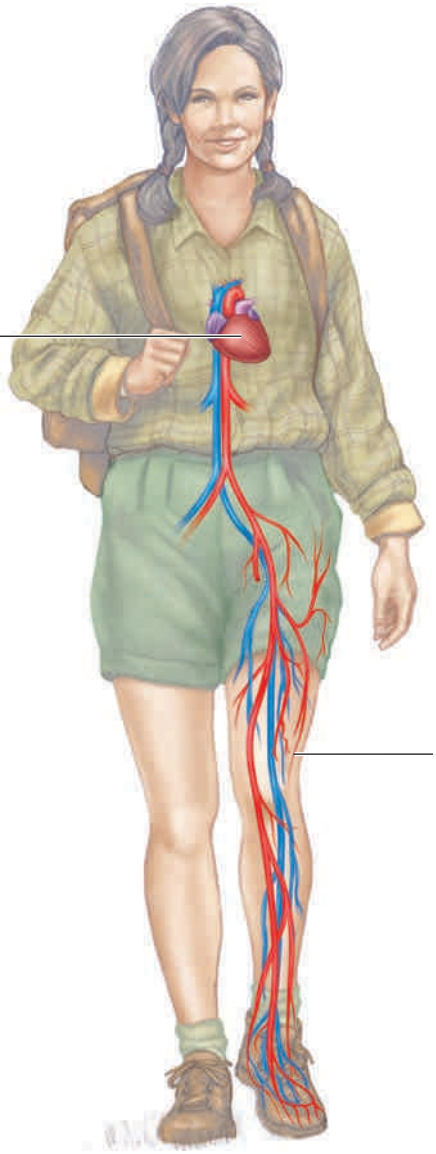
the force exerted by the blood on artery walls. As shown in Figure 27-3, blood pressure depends on the volume of blood pumped by the heart (cardiac output) and the resistance the blood encounters in the arterioles (peripheral resistance). ◆ When either cardiac output or peripheral resistance increases, blood pressure rises. Cardiac output is raised when heart rate or blood volume increases; peripheral resistance is affected mostly by the diameters of the arterioles and blood viscosity. Blood pressure is therefore influenced by the nervous system (which regulates heart muscle contractions and the arterioles' diameters) and hormonal signals (which may cause fluid retention or blood vessel constriction). The kidneys also play a role in regulating blood pressure by controlling the secretion of the hormones involved in vasoconstriction and retention of sodium and water.

◆ The equation describing this relationship is: blood pressure (BP) = cardiac output (CO) × peripheral resistance (PR)

Factors That Contribute to Hypertension

In 90 to 95 percent of hypertension cases, the cause is unknown (called **primary** or **essential hypertension**).[65] In other cases, hypertension results from a known physical or metabolic disorder **(secondary hypertension)**, such as an abnor-

FIGURE 27-3 Determinants of Blood Pressure



primary hypertension: hypertension with an unknown cause; also known as **essential hypertension.**

secondary hypertension: hypertension that results from a known physiological abnormality.

Screening people for hypertension is a first step toward early detection and prevention of complications.

◆ *Salt sensitivity* is also known as *sodium sensitivity*. Salt is the main source of sodium in the diet.

◆ The goal of hypertension treatment is to reduce blood pressure to <140/<90 mm Hg. For people with diagnosed CHD, diabetes, or kidney disease, the blood pressure goal is <130/<80 mm Hg.

◆ Prehypertension: 120–139/80–89 mm Hg.

mality in an organ or hormone involved in blood pressure regulation. For example, chronic kidney disease interferes with the removal of sodium and water from blood, directly increasing blood volume and thus blood pressure. Atherosclerosis in renal arteries may cause increased production of the hormones that stimulate water retention and vasoconstriction. Stiffness and thickening of the aorta or arteries (arteriosclerosis) due to age, diabetes, or other reasons can increase resistance to blood flow, thereby raising blood pressure.

A number of risk factors have been identified in the development of hypertension. These include the following:

- *Aging*. Hypertension risk increases with age. Over two-thirds of persons older than 65 years have hypertension.[66] Moreover, individuals who have normal blood pressure at age 55 still have a 90 percent risk of developing high blood pressure during their lifetimes.[67]
- *Genetic factors*. Risk of hypertension is similar among family members. It is also more prevalent and severe in certain ethnic groups; for example, the prevalence in African Americans is about 41 percent, compared with a prevalence of about 28 percent in whites and Mexican Americans.[68]
- *Obesity*. Of people with hypertension, most—an estimated 60 percent—are obese.[69] Obesity raises blood pressure, in part, by altering kidney function and promoting fluid retention.[70]
- *Salt sensitivity*. ◆ Among those with hypertension, approximately 30 to 50 percent are sensitive to salt and can improve blood pressure by reducing salt consumption.[71]
- *Alcohol*. Heavy alcohol consumption (defined as three or more drinks daily) is strongly associated with hypertension. Alcohol's specific role in blood pressure is unclear.[72]
- *Dietary factors*. A person's diet may increase risk for hypertension. As explained later, dietary modifications that increase intakes of potassium, calcium, and magnesium have been shown to reduce blood pressure.

Treatment of Hypertension

Controlling hypertension improves CVD risk considerably: a blood pressure reduction of 10/5 mm Hg lowers the risks of death from CHD and stroke by about 45 and 55 percent, respectively.[73] Both lifestyle modifications and drug therapies are used to treat hypertension. ◆ For people with prehypertension, ◆ changes in diet and lifestyle alone may lower blood pressure to a normal level.

Table 27-4 describes the lifestyle modifications recommended for reducing blood pressure and the expected reduction in systolic blood pressure for each change. The recommendations include weight reduction if overweight or obese; a diet low in sodium and rich in potassium, calcium, and magnesium; regular physical activity; and a moderate alcohol intake.[74] Combining two or more of these modifications can enhance results. As Table 27-4 shows, weight reduction and dietary changes generally have the most dramatic effects on blood pressure.

Weight Reduction Weight reduction can reduce blood pressure considerably. In controlled studies, participants who lost 22 pounds (10 kilograms) lowered systolic blood pressure by an average of 7.0 mm Hg, and greater weight loss was associated with greater reductions in blood pressure.[75] The improvement persisted for at least one and a half years, and the prevalence of hypertension among participants was found to be 20 to 50 percent lower among those who lost weight.

Dietary Approaches for Reducing Blood Pressure Several research studies have shown that a significant reduction in blood pressure can be achieved by following a diet that emphasizes fruits, vegetables, and low-fat dairy products and

TABLE 27-4 Lifestyle Modifications for Blood Pressure Reduction

Modification	Recommendation	Expected Reduction in Systolic Blood Pressure
Weight reduction	Maintain healthy body weight (BMI below 25).	5–20 mm Hg/10 kg lost
DASH eating plan	Adopt a diet rich in fruits, vegetables, and low-fat milk products with reduced saturated fat intake.	8–14 mm Hg
Sodium restriction	Reduce dietary sodium intake to less than 2400 mg sodium (less than 6 g salt) per day.[a]	2–8 mm Hg
Physical activity	Perform aerobic physical activity for at least 30 minutes per day, most days of the week.	4–9 mm Hg
Moderate alcohol consumption	Men: Limit to 2 drinks per day. Women and lighter-weight men: Limit to 1 drink per day.	2–4 mm Hg

[a] According to DRI recommendations, sodium intake should be limited to 2300 mg daily.
SOURCE: Adapted from *Reference Card from the Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 7),* NIH publication no. 03-5231 (Bethesda, Md.: National Institutes of Health, National Heart, Lung, and Blood Institute, and National High Blood Pressure Education Program, May 2003).

includes whole grains, poultry, fish, and nuts.[76] The diet tested in these studies, now known as the *DASH Eating Plan,* ◆ provides more fiber, potassium, magnesium, and calcium than the typical American diet. The diet also limits red meat, sweets, sugar-containing beverages, saturated fat (to 7 percent of kcalories), and cholesterol (to 150 milligrams per day), so it is beneficial for reducing CHD risk as well. During the eight-week study period when hypertensive subjects consumed the DASH diet, their systolic blood pressures fell by 11.4 mm Hg more than the blood pressures of subjects who remained on the standard American control diet.[77] The DASH Eating Plan, shown in Table 27-5 on p. 860, is a dietary pattern that meets the goals specified in the *Dietary Guidelines for Americans 2005.*[78]

◆ The DASH Eating Plan was the test diet used in a study called *D*ietary *A*pproaches to *S*top *H*ypertension.

The DASH Eating Plan is even more effective when accompanied by a low sodium intake. In a research study that tested the blood pressure–lowering effects of the DASH dietary pattern in combination with sodium restriction, the best results were achieved when sodium was reduced to 1500 milligrams daily—a lower level than the maximum intake of 2400 milligrams ◆ recommended for people with hypertension.[79] These results suggest that the optimal sodium intake for people with hypertension may be far lower than is typically recommended.

◆ The maximum sodium intake recommended for people with hypertension (2400 mg) is similar to the Tolerable Upper Intake Level (UL) for sodium, which was set at 2300 mg to prevent the adverse effects of high sodium intakes on blood pressure in the general population.

Sodium restriction by itself can have a modest blood pressure–lowering effect (review Table 27-4), but some people are more responsive than others. Although a low-sodium diet may improve blood pressure to some extent, it should be combined with other lifestyle modifications for greater effect. The "How to" on p. 860 lists practical suggestions for restricting sodium intake; additional detail is provided in Table 28-1 on p. 877.

Drug Therapies for Reducing Blood Pressure Most people with hypertension use two or more medications to meet their blood pressure goals. Using a combination of drugs with different modes of action can reduce the doses of each drug needed and minimize side effects. Most treatments include diuretics, which lower blood pressure by reducing blood volume. ◆ Other medications commonly prescribed include ACE inhibitors ◆, beta-blockers, and calcium channel blockers; these drugs are also used to treat various heart conditions. Drug doses may need to be adjusted in follow-up visits until the blood pressure goal is reached. The Diet-Drug Interactions feature lists nutrition-related side effects of using these medications (see p. 855).

◆ Some diuretics may cause potassium depletion. When these diuretics are used, serum potassium levels are monitored several times yearly, and supplements are prescribed when necessary.

◆ *ACE* stands for *angiotensin-converting enzyme.* An ACE inhibitor interferes with the conversion of angiotensin I to angiotensin II, which is a peptide that helps to regulate blood pressure.

TABLE 27-5 The DASH Eating Plan

Food Group	Recommended Servings for Different Energy Intakes (servings per day except as noted)			
	1600 kcal	2000 kcal	2600 kcal	3100 kcal
Grains and grain products[a] (1 serving = 1 slice bread, 1 oz dry cereal,[b] or ½ cup cooked rice, pasta, or cereal)	6	7–8	10–11	12–13
Vegetables (1 serving = ½ cup cooked vegetables, 1 cup raw leafy vegetables, or 6 oz vegetable juice)	3–4	4–5	5–6	6
Fruits (1 serving = 1 medium fruit; ½ cup fresh, frozen, or canned fruit; ¼ cup dried fruit; or 6 oz fruit juice)	4	4–5	5–6	6
Milk products (low-fat or fat-free) (1 serving = 8 oz milk, 1 cup yogurt, or 1½ oz cheese)	2–3	2–3	3	3–4
Meat, poultry, and fish (1 serving = 3 oz cooked meat, poultry, or fish)	1–2	1–2	2	2–3
Nuts, seeds, and legumes (1 serving = ⅓ cup nuts, 2 tbs seeds, or ½ cup cooked dry beans or peas)	3–4 per week	4–5 per week	1	1
Fats and oils (1 serving = 1 tsp vegetable oil or soft margarine, 1 tbs low-fat mayonnaise, or 2 tbs light salad dressing)	2	2–3	3	4
Sweets (1 serving = 1 tbs sugar, jelly, or jam; ½ oz jelly beans; or 8 oz lemonade)	0	5 per week	2	2

[a]Whole grains are recommended for most servings consumed.
[b]1 oz dry cereal may be equivalent to ½ to 1¼ cups, depending on the cereal. Check the food label for the portion size.
SOURCE: The 2005 *Dietary Guidelines for Americans,* available at **www.healthierus.gov/dietaryguidelines**.

HOW TO Reduce Sodium Intake

- Select fresh, unprocessed foods. Packaged foods, canned goods, and frozen meals are often high in sodium.
- Do not use salt at the table or while cooking. Salt substitutes may be useful for some people. Salt substitutes often contain potassium, however, and are not appropriate for people using diuretics that promote potassium retention in the blood.
- Avoid eating in fast-food restaurants; most menu choices are very high in sodium.
- Check food labels. The labeling term *low sodium* is a better guide than the terms *reduced sodium* (contains 25 percent less sodium than the regular product) or *light in sodium* (contains 50 percent less sodium). To be labeled *low sodium,* a food product must contain less than 140 milligrams of sodium per serving. Keep your goal sodium level (about 2400 milligrams) in mind when you read labels.
- Recognize the high-sodium foods in each food category, and purchase only unsalted or low-sodium varieties of these products if they are available. High-sodium foods include the following:
  - Snack foods made with added salt, such as tortilla chips, popcorn, and nuts.
  - Processed meats, such as ham, corned beef, bologna, salami, sausage, bacon, frankfurters, and pastrami.
  - Processed fish, such as salted fish and canned fish.
  - Tomato-based products, such as tomato sauce, tomato juice, pizza, canned tomatoes, and catsup.
  - Canned soups and broths; note that even reduced-sodium varieties may contain excessive sodium.
  - Cheese, such as cottage cheese, American cheese, and Parmesan and most other hard cheeses.
  - Bakery products made with baking powder or baking soda (sodium bicarbonate), such as cakes, cookies, cupcakes, doughnuts, and muffins.
  - Condiments and relishes, such as bouillon cubes, olives, and pickled vegetables.
  - Flavoring sauces, such as soy sauce, barbecue sauce, and steak sauce.
- Check for the word *sodium* on medication labels. Sodium is often an ingredient in some types of antacids and laxatives.

IN SUMMARY

Nearly one in three persons in the United States has hypertension, which increases the risk of developing CHD, heart failure, stroke, and kidney failure. Blood pressure is elevated by factors that increase blood volume, heart rate, and resistance to blood flow. Although the underlying cause of most cases of hypertension is unknown, major risk factors include aging, family history, ethnicity, obesity, and dietary factors. Treatment usually includes a combination of lifestyle modifications and drug therapies. The Case Study below provides an opportunity to review the risk factors and treatments for CHD and hypertension.

CASE STUDY Computer Programmer with Cardiovascular Disease

Andrew Reid, a 48-year-old African American computer programmer, is 5 feet 9 inches tall and weighs 240 pounds. He sits for long hours at work and is too tired to exercise when he gets home at night. His meals usually include fatty meats, eggs, and cheese, and he likes dairy desserts such as pudding and ice cream. He has a family history of CHD and hypertension. His recent laboratory tests show that his blood pressure is 160/100 mm Hg, and his LDL and HDL levels are 160 mg/dL and 35 mg/dL, respectively. He smokes a pack of cigarettes each day and usually has two glasses of wine at both lunch and dinner.

1. Name Mr. Reid's major risk factors for CHD and hypertension. Which can be modified? What complications might occur if he doesn't seek treatment for his blood lipids and blood pressure?
2. What dietary changes would you recommend that could help to improve Mr. Reid's blood pressure and his LDL and HDL cholesterol? Explain the rationale for each dietary change. Prepare a day's menus for Mr. Reid using the DASH diet as an outline for your choices.
3. What other laboratory tests or measurements would you need to better assess Mr. Reid's condition? Why?
4. Describe several benefits that Mr. Reid might obtain from a program that includes weight reduction and regular physical activity. Explain why the use of alcohol can be both a protective and a damaging lifestyle habit.
5. Assuming that Mr. Reid does not make any changes in his diet and lifestyle and suffers a heart attack, describe the elements of a cardiac rehabilitation program that would be critical for his long-term survival.

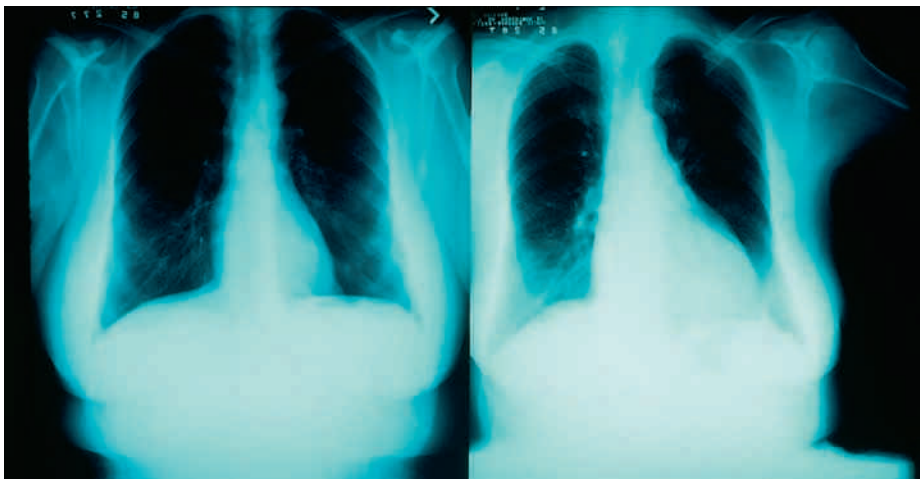
Heart Failure

Heart failure, also called *congestive heart failure,* is characterized by the heart's inability to pump adequate blood to meet the metabolic needs of the body's cells, resulting in a buildup of fluids in the veins and tissues. Heart failure has multiple causes; it is often a consequence of other cardiovascular conditions that create extra work for the heart muscle, such as hypertension and CHD. To accommodate the extra workload, the heart responds by enlarging or pumping faster or harder, but it eventually may weaken enough to fail completely. Heart failure develops mostly in older adults and the elderly: approximately 75 percent of persons with heart failure in the United States are aged 65 or older.[80]

Consequences of Heart Failure

The symptoms and consequences of heart failure depend on the side of the heart that fails. The right side of the heart normally pumps blood from the peripheral tissues to the lungs. With impaired pumping, blood backs up in the peripheral tissues and abdominal organs. Fluid can accumulate in the lower extremities and in

heart failure: a condition with multiple causes characterized by the heart's inability to pump adequate blood to the body's cells, resulting in fluid accumulation in the tissues; also called *congestive heart failure.*



© Susan Leavines/Photo Researchers, Inc.

An overburdened heart enlarges in an effort to supply blood to the body's tissues.

the liver and abdomen, causing chest pain, difficulty with digestion and absorption, and swelling in the legs, ankles, and feet. The left side of the heart pumps blood from the lungs to the peripheral tissues. A weakened left heart can cause a buildup of fluid in the lungs (pulmonary edema), resulting in extreme shortness of breath and limited oxygen for activity; in severe cases, it can lead to acute respiratory failure. The inadequate blood flow to tissues can impair the functions of various organs, such as the liver and kidneys. The effects of heart failure also depend on the seriousness of the disease: mild cases may be asymptomatic, but severe cases may restrict activity substantially.

The type of heart failure a person develops has implications that affect food intake and physical activity. Because right-sided heart failure can cause abdominal bloating and an enlarged liver, pain and discomfort may worsen with meals. Left-sided failure may limit physical activity substantially due to limb weakness and fatigue. End-stage heart failure is often accompanied by **cardiac cachexia**, a condition of malnutrition brought about by changes in body chemistry (including increased secretion of proinflammatory cytokines and catabolic hormones) and worsened by reduced appetite and food intake. Cardiac cachexia causes severe weight loss and tissue wasting. The resultant weakness further lowers the person's activity levels, functional capacity, and strength.

Medical Management of Heart Failure

Heart failure is a chronic, progressive condition that may require frequent hospitalizations. Many patients face a combination of debilitating symptoms, complex treatments, and an uncertain outcome. Important goals of medical therapy are to enhance the patient's quality of life and to slow disease progression. Successful treatment depends on patient participation and compliance with medications and dietary restrictions.

The specific treatment for heart failure depends on the nature and severity of the illness. In general, medications help to manage fluid retention and improve heart function. Dietary sodium and fluid restrictions may help to prevent fluid accumulation. Vaccinations for influenza and pneumonia reduce the risk of developing respiratory infections. Treatment of CHD risk factors, such as hypertension and lipid disorders, may help to slow disease progression. Heart failure patients are also encouraged to participate in exercise programs to avoid becoming physically disabled and to improve endurance.

Drug Therapies for Heart Failure The medications routinely prescribed for heart failure include diuretics, ACE inhibitors, angiotensin receptor blockers, beta-blockers, vasodilators, and digitalis.[81] The diuretics are given to reverse or prevent fluid retention. The patient must monitor fluid fluctuations with daily weight

cardiac cachexia: the severe muscle wasting and weight loss that accompany heart failure.

measurements and can make small adjustments in the diuretic dose as needed. The other drugs listed help to improve heart and blood vessel functioning and blood flow.

Nutrition Therapy for Heart Failure The main dietary recommendation for heart failure is a moderate sodium restriction of 2000 milligrams or less daily, depending on the severity of the illness.[82] ◆ The sodium restriction reduces the likelihood of fluid retention. Under some circumstances, fluid restriction is also necessary. For patients who have difficulty eating due to abdominal or chest pain, small, frequent meals may be better tolerated than larger meals.

◆ The recommendation of 2000 mg of sodium is not very restrictive. The current DRI recommendation is to limit sodium intake to 2300 mg daily.

Other Dietary Recommendations Patients with heart failure may be prone to constipation due to diuretic use and reduced physical activity. Maintaining an adequate fiber intake can help to minimize constipation problems. Because of alcohol's deleterious effects on blood pressure and heart function, most patients need to restrict or avoid alcoholic beverages.

Cardiac Cachexia No known therapies can reverse cardiac cachexia, and prognosis is poor. For some patients, liquid supplements, tube feedings, or parenteral nutrition support can be supportive additions to treatment.

IN SUMMARY

Heart failure is usually a chronic, progressive condition that results from other cardiovascular illnesses. In heart failure, the heart is unable to pump adequate blood to tissues. Consequences may include fluid accumulation in the veins, lungs, and other organs and impaired organ function. Treatment of heart failure includes drug therapies that reduce fluid accumulation and strengthen heart function. The main dietary recommendation is a moderate sodium restriction.

Stroke

Stroke is the third leading cause of death in the United States after heart disease and cancer, and it is the most common cause of significant disability in adults.[83] About 87 percent of strokes are **ischemic strokes,** caused by the obstruction of blood flow to brain tissue. **Hemorrhagic strokes** occur in 13 percent of cases and result from bleeding within the brain, which damages brain tissue.[84] Most ischemic strokes are a result of atherosclerotic plaque rupture and thrombosis, ◆ but an embolism ◆ may also cause a stroke. Hemorrhagic strokes often result from rupture of a blood vessel that has been weakened by atherosclerosis and chronic hypertension. Hemorrhagic strokes are generally more deadly: 38 percent result in death within 30 days.[85]

◆ Reminder: *Thrombosis* is the formation of a blood clot (a *thrombus*).

◆ Reminder: An *embolism* is the obstruction of a blood vessel by a traveling blood clot or air bubble (an *embolus*).

Strokes that occur suddenly and are short-lived (lasting several minutes to several hours) are called **transient ischemic attacks (TIAs)**. These brief strokes are a warning sign that a heart attack or a more severe stroke may follow, and they need to be evaluated quickly.[86] TIAs typically cause short-term neurological symptoms, such as confusion, slurred speech, numbness, paralysis, or difficulty speaking. Treatment includes the use of aspirin and other drugs that inhibit blood clotting.

ischemic strokes: strokes caused by the obstruction of blood flow to brain tissue.

hemorrhagic strokes: strokes caused by bleeding within the brain, which destroys or compresses brain tissue.

transient ischemic attacks (TIAs): brief ischemic strokes that cause short-term neurological symptoms.

Stroke Prevention

Stroke is largely preventable by recognizing its risk factors and making lifestyle choices that reduce risk. Many of the risk factors are similar to those for heart disease; they include hypertension, cigarette smoking, diabetes mellitus, elevated

LDL cholesterol levels, and a history of cardiovascular disease. Medications that suppress blood clotting reduce the risk of ischemic stroke, especially in people who have suffered a first stroke or a transient ischemic attack. The drugs prescribed typically include antiplatelet drugs (such as aspirin and clopidogrel) and anticoagulants (such as warfarin). ◆ Anticoagulant therapy requires regular follow-up and occasional adjustments in dosage to prevent excessive bleeding.

◆ Warfarin acts by interfering with vitamin K's blood-clotting function (see Chapter 19, p. 651).

Stroke Management

The effects of a stroke vary according to the area of the brain that has been injured. Body movements, senses, and speech are often impaired, and one side of the body may be weakened or paralyzed. Early diagnosis and treatment are necessary to preserve brain tissue and minimize long-term disability. Thrombolytic (clot-busting) drugs are given within the first few hours following an ischemic stroke to prevent further brain damage.[87]

The focus of nutrition care is to help patients maintain nutrition status and overall health despite the disabilities caused by the stroke. Some patients may need to learn about dietary treatments that improve blood lipid levels and blood pressure. Dysphagia (difficulty swallowing) is a frequent complication of stroke and is associated with a poorer prognosis. Difficulty with speech prevents patients from describing the problems they may be having with eating and from communicating their food preferences. Coordination problems can make it hard for stroke patients to grasp utensils or bring food from table to mouth. In some cases, tube feedings may be necessary until the patient has regained these skills. Highlight 27 describes additional options for feeding people with disabilities, such as those that follow stroke.

IN SUMMARY

The two major types of strokes, ischemic and hemorrhagic stroke, may be a consequence of atherosclerosis, hypertension, or both. Transient ischemic attacks, which are short-lived ischemic strokes, are a warning sign that a heart attack or a more severe stroke may follow. Strokes are largely preventable by reversing modifiable risk factors, such as hypertension, cigarette smoking, diabetes mellitus, and elevated LDL cholesterol. Treatment of a stroke includes the use of anticlotting drugs such as antiplatelet drugs and anticoagulants. A patient who has had a major stroke may have problems eating normally due to lack of coordination and difficulty swallowing.

Clinical Portfolio

1. List the risk factors for coronary heart disease, and identify possible interrelationships among the factors. For example, a woman over age 55 is also at risk for diabetes; a person with diabetes is more likely to have hypertension.

2. Review the DASH Eating Plan shown in Table 27-5. As the chapter described, the DASH dietary pattern is helpful for lowering blood pressure and for reducing CHD risk as well.
   - List elements of the DASH diet that are consistent with the TLC recommendations.
   - Suggest ways in which a person following the DASH diet might accomplish the following additional dietary modifications: consume a higher percentage of fat from monounsaturated sources, reduce intake of *trans*-fatty acids, and include EPA/DHA and plant sterols.

NUTRITION ON THE NET

For further study of topics covered in this chapter, log on to **academic.cengage.com/nutrition/rolfes/UNCN8e**. Go to Chapter 27, then to Nutrition on the Net.

- To search for additional information about cardiovascular diseases, obtain the American Heart Association dietary guidelines, or find links to other relevant materials, visit the website of the American Heart Association: **www.americanheart.org**
- Information about cardiovascular diseases, the DASH Eating Plan, and implementation of heart-healthy diets is available at the websites of the National Heart, Lung, and Blood Institute and the Heart and Stroke Foundation of Canada: **www.nhlbi.nih.gov** and **ww2.heartandstroke.ca**
- To learn about improving health care and life expectancy of ethnic minority populations at high risk for cardiovascular diseases, visit the website of the International Society on Hypertension in Blacks: **www.ishib.org**

NUTRITION ASSESSMENT CHECKLIST for People with Cardiovascular Disease

Medical History

Check the medical record for a diagnosis of:

- Coronary heart disease
- Hypertension
- Heart failure
- Strokes

Review the medical record for complications related to cardiovascular diseases:

- Heart attacks
- Transient ischemic attacks
- Cardiac cachexia

Note risk factors for CHD related to diet, including:

- Elevated LDL or triglyceride levels
- Obesity or overweight
- Diabetes
- Hypertension

Medications

For patients using drug treatments for cardiovascular diseases, note:

- Side effects that may alter food intake
- Medications that may interact with grapefruit juice
- Use of warfarin, which influences vitamin K intake
- Use of diuretics associated with potassium imbalances
- Potential diet-drug or herb-drug interactions

Dietary Intake

For patients with CHD or hypertension, assess the diet for:

- Energy intake
- Saturated fat, *trans* fat, cholesterol, and sodium content
- Soluble fiber and soy protein content
- Intake of whole grains, fruits, vegetables, legumes, and nuts
- Alcohol

For patients with complications related to cardiovascular diseases:

- Check adequacy of food intake in patients with heart failure.
- Check physical disabilities that may interfere with food preparation or consumption following a stroke.

Anthropometric Data

Measure baseline height and weight, and reassess weight at each medical checkup. Note whether patients are meeting weight goals, including:

- Weight loss or maintenance in patients who are overweight
- Weight maintenance in patients with advanced heart failure

Remember that weight may be deceptively high in people who are retaining fluids, especially individuals with heart failure.

Laboratory Tests

Monitor the following laboratory tests in people with cardiovascular diseases:

- LDL cholesterol, triglycerides, and HDL cholesterol
- Blood glucose in patients with diabetes
- Blood potassium in patients using diuretics or cardiac glycosides
- Indicators of fluid retention in patients with heart failure
- Blood-clotting times in patients using anticoagulants

Physical Signs

Blood pressure measurement is routine in physical exams, but is especially important for people who:

- Have cardiovascular diseases
- Have experienced a heart attack or stroke
- Have risk factors for CHD or hypertension

Look for signs of:

- Potassium imbalances (muscle weakness, numbness and tingling, irregular heartbeat) in those using diuretics or cardiac glycosides
- Fluid overload in patients with heart failure

STUDY QUESTIONS

CENGAGENOW™

To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Define atherosclerosis. What are the medical problems that may result from atherosclerosis? (pp. 841–842)
2. Explain how atherosclerosis progresses. Discuss the factors that contribute to atherosclerosis development. (pp. 842–845)
3. Discuss the symptoms that may develop in coronary heart disease. Explain how risk for coronary heart disease is evaluated. (pp. 845–847)
4. Describe each of the Therapeutic Lifestyle Changes recommended for reducing risk of coronary heart disease. (pp. 847–852)
5. How is hypertriglyceridemia treated? Compare the dietary recommendations for mild and severe cases. (pp. 852–854)

6. Describe the medical treatment provided after a heart attack. What information is typically provided in cardiac rehabilitation programs? (pp. 855–856)
7. What are the possible consequences of hypertension? Discuss the major risk factors associated with hypertension and the lifestyle modifications that may lower blood pressure. (pp. 856–861)
8. Compare the effects of right-sided and left-sided heart failure. Describe the elements of treatment for heart failure. (pp. 861–863)
9. Describe the difference between an ischemic stroke and a hemorrhagic stroke. What are possible consequences of a stroke? How might it affect an individual's nutrition care? (pp. 863–864)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 867.

1. Ischemia in the coronary arteries is a frequent cause of:
   a. angina pectoris.
   b. hemorrhagic stroke.
   c. aneurysm.
   d. hypertension.
2. Risk factors for atherosclerosis include all of the following *except:*
   a. smoking.
   b. hypertension.
   c. diabetes mellitus.
   d. elevated HDL cholesterol.
3. The dietary lipids with the strongest LDL cholesterol–raising effects are:
   a. monounsaturated fats.
   b. polyunsaturated fats.
   c. saturated fats.
   d. plant sterols.
4. The omega-3 fatty acids EPA and DHA, which may improve some risk factors for heart disease, are obtained by consuming:
   a. fatty fish.
   b. soy products.
   c. egg yolks and organ meats.
   d. nuts and seeds.
5. Moderate alcohol consumption can improve heart disease risk, in part, because it:
   a. lowers blood pressure.
   b. improves nutrition status.
   c. offsets the damage from smoking.
   d. increases HDL cholesterol levels.
6. Patients with mild hypertriglyceridemia may improve their triglyceride levels by:
   a. reducing sodium intake.
   b. consuming moderate amounts of alcohol.
   c. avoiding a high carbohydrate intake.
   d. reducing cholesterol intake.
7. In most cases of hypertension, the cause is:
   a. excessive alcohol use.
   b. atherosclerosis.
   c. hormonal imbalances.
   d. unknown.
8. Hypertensive patients can benefit from all of the following dietary and lifestyle modifications *except:*
   a. including fat-free or low-fat milk products in the diet.
   b. reducing total fat intake.
   c. consuming generous amounts of fruits, vegetables, legumes, and nuts.
   d. reducing sodium intake.
9. Nutrition therapy for a patient with heart failure usually includes:
   a. weight loss.
   b. reducing total fat intake.
   c. sodium restriction.
   d. cholesterol restriction.
10. Hemorrhagic stroke:
    a. is the most common type of stroke.
    b. results from obstructed blood flow within brain tissue.
    c. comes on suddenly and usually lasts for up to 30 minutes.
    d. results from bleeding within the brain, which damages brain tissue.

Feeding Disabilities

Chapter 27 referred to difficulties following a stroke that can interfere with the ability to eat independently. This highlight discusses the problems faced by individuals who must cope with disabilities that interfere with the process of eating, such as those that interfere with chewing and swallowing. These obstacles can arise at any time during a person's life and from any number of causes. An infant may be born with a physical impairment such as cleft palate; an adolescent may lose motor control following injuries sustained in an automobile accident; an older adult may struggle with the pain of arthritis or the mental deterioration of dementia. Table H27-1 lists some of the conditions that may lead to feeding problems.

Effects of Disabilities on Nutrition Status

Eating and drinking require a considerable number of individual coordinated motions. Consider an infant learning the skills required for feeding: each step—sitting, grasping cups and utensils, bringing food to the mouth, biting, chewing, and swallowing—requires coordinated movements. An injury or disability that interferes with any of these movements can lead to feeding problems and inadequate food intake. Total food intake is often significantly reduced when individuals with inefficient motor function take a long time to eat.[1] Difficulties that affect procurement of food, such as the inability to drive, walk, or carry groceries, can also lower food intake and lead to malnutrition and weight loss.

TABLE H27-1 Conditions That May Lead to Feeding Problems

The following conditions may lead to feeding problems by interfering with a person's ability to suck, bite, chew, swallow, or coordinate hand-to-mouth movements.

- Accidents
- Amputations
- Arthritis
- Birth defects
- Cerebral palsy
- Cleft palate
- Down syndrome
- Head injuries
- Huntington's chorea
- Language, visual, or hearing impairment
- Multiple sclerosis
- Muscle weakness
- Muscular dystrophy
- Neuromotor dysfunction
- Parkinson's disease
- Polio
- Spinal cord injuries
- Stroke

Energy Requirements

Disabilities may either increase or decrease energy needs. Those that affect muscle tension and mobility can reduce physical activity and, consequently, energy requirements. Other disabilities, such as certain forms of cerebral palsy, cause involuntary muscle activity that raises energy requirements.[2] Loss of a limb due to amputation reduces energy needs in proportion to the weight and metabolism represented by the missing limb, but energy needs may be greater if an individual increases activity to compensate for the loss, such as by propelling a wheelchair. Because the effects of disabilities are often unpredictable, the health care practitioner may find it difficult to assess energy requirements until weight gain or loss has occurred.

Overweight and obesity often accompany conditions that limit mobility or result in short stature; examples include Down syndrome (see p. 498) and spina bifida (see p. 481). Obesity may also develop because the family or caregiver provides an inappropriate amount of food, sometimes out of sympathy for the individual who has a disability.[3] In these cases, the health practitioner may need to counsel the family or caregiver about appropriate food choices and portion sizes.

Effects of Disease Symptoms and Medications

Physical symptoms of disease sometimes interfere with eating and nutrition status. Examples include nausea, frequent coughing or choking, difficulty breathing, and gastroesophageal reflux. Individuals with speech and hearing problems may have a difficult time communicating with caregivers about thirst and hunger. Mobility problems can lead to bone demineralization and pressure sores.

Conditions that require the use of multiple medications can also have a significant impact on nutrition status (see Chapter 19).[4] Medications may increase or decrease appetite, interfere with nutrient metabolism, or have gastrointestinal effects that cause pain or discomfort with eating.

Social Concerns

Because mealtimes are a critical time for social interaction, individuals with feeding problems may encounter emotional and social problems if they are unable to participate. Children may fail to develop social skills, whereas adults may miss the social stimulation that mealtimes provide. Individuals should be encouraged to sit with family and friends during meals so that they are not deprived of the social and cultural aspects of eating.

Independent Eating for People with Disabilities

The evaluation and treatment of feeding problems often involve the joint efforts of health care professionals from a variety of disciplines, including dietitians, nurses, occupational and physical therapists, speech-language pathologists, and dentists. Together, these professionals evaluate each patient's dietary needs and assess abilities to chew, sip, swallow, grasp utensils, use utensils to pick up foods, and bring foods from the plate to the mouth. A speech-language pathologist most often evaluates chewing and swallowing abilities and trains patients to use lips, tongue, and throat for eating and speaking. An occupational therapist can demonstrate alternate feeding strategies, including changes in body position that improve feeding, techniques for handling utensils and food, and use of special feeding devices.

Feeding Strategies

Direct observation of a patient during mealtimes allows health care professionals to assess current eating behaviors, demonstrate feeding techniques, monitor the patient's and caregiver's understanding of the techniques, and evaluate how well the care plan is working. To illustrate, consider a child with a feeding problem caused by hypersensitivity to oral stimulation. The health care professional may start by teaching the caregiver to gently and playfully stroke the child's face with a hand, washcloth, or soft toy. Once the child tolerates touch on less sensitive areas of the face, the health care professional may encourage the caregiver to slowly begin to rub the child's lips, gums, palate, and tongue. With time, the child may be better able to tolerate the presence of food in the mouth. Examples of other strategies that can help feeding problems are listed in Table H27-2.

Adaptive Feeding Equipment

Adaptive feeding devices can make a remarkable difference in a person's ability to eat independently. Figure H27-1 on p. 870 shows a few of the many special feeding devices that are available and describes their uses. Other examples of adaptive equipment include specialized chairs to improve posture, bolsters inserted under arms to improve elbow stability, and raised trays or eating surfaces to simplify hand-to-mouth movements.[5]

Sometimes, despite the best efforts of all involved, a patient is unable to consume enough food by mouth. In these cases, tube feedings can help to improve nutrition status. Tube feedings are also recommended for patients who have severe dysphagia (difficulty swallowing) or aspiration pneumonia.[6]

A Note for Caregivers

The responsibility of caring for a person with a feeding problem can frequently overwhelm a caregiver. Caring for a person with disabilities requires time and patience—and many new therapies to be learned and administered. The caregiver may spend many

© Courtesy of Sammons Preston/Patterson Medical Products, Inc.

Adaptive feeding equipment can help patients with feeding disabilities gain independence.

TABLE H27-2 Interventions for Feeding-Related Problems

Inability to Suck

- Use squeeze bottles, which do not require sucking, to express liquids into the mouth.
- Place a spoon on the center of the tongue and apply downward pressure to stimulate sucking.
- Apply rhythmic, slow strokes on the tongue to alter the tongue position and improve the sucking response.

Inability to Chew

- Place foods between gums and teeth to promote chewing.
- Improve chewing skills with foods of different textures; for example, fruit leathers stimulate jaw movements but dissolve quickly enough to minimize choking.
- Provide soft foods that require minimal chewing or are easily chewed.

Inability to Swallow

- Provide thickened liquids, pureed foods, and moist foods that form boluses easily.
- Provide cold formulas, frozen fruit juice bars, and ice; cold substances promote swallowing movements by the tongue and soft palate.
- Make sure the patient's jaw and lips are closed to facilitate swallowing action.
- Correct posture and head position if they interfere with swallowing ability.

Inability to Grasp or Coordinate Movements

- Provide utensils that have modified handles, or are smaller or larger as necessary.
- Encourage the use of hands for feeding if utensils are difficult to maneuver.
- Provide plates with food guards to prevent spilling.
- Supply clothing protection.

Impaired Vision

- Place foods (meats, vegetables) in similar locations on the plate at each meal.
- Provide plates with food guards to prevent spilling.

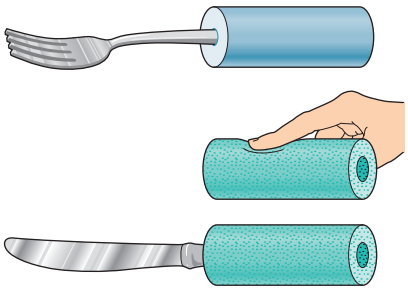
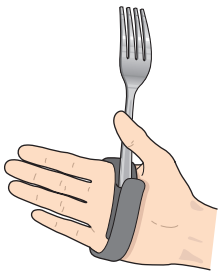
Roller knife

People with only one arm or hand may have difficulty cutting foods and may appreciate using a *rocker knife* or a *roller knife.*

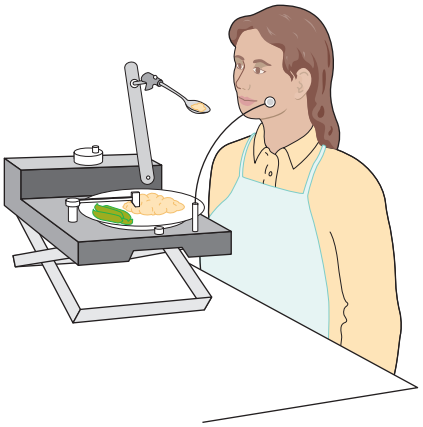


People with a limited range of motion can feed themselves better when they use *flatware with built-up handles.*



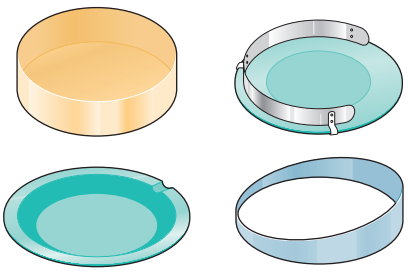
People with extreme muscle weakness may be able to eat with a *utensil holder.*

For people with tremors, spasticity, and uneven jerky movements, *weighted utensils* can aid the feeding process.

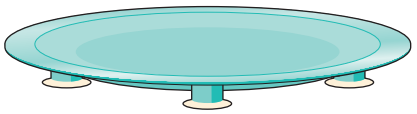


Battery-powered feeding machines enable people with severe limitations to eat with less assistance from others.

Plates

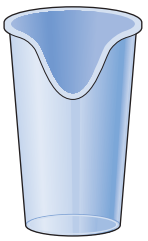


People who have limited dexterity and difficulty maneuvering food find *scoop dishes* or *food guards* useful.

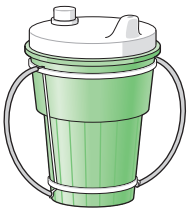


People with uncontrolled or excessive movements might move dishes around while eating and may benefit from using *unbreakable dishes with suction cups.*

Cups

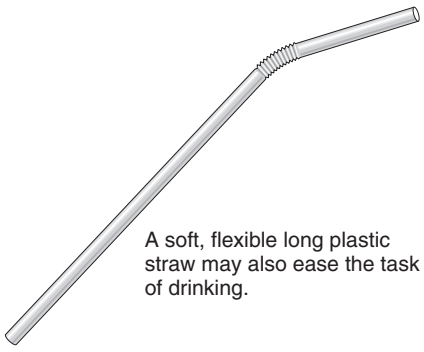


People with limited neck motion can use a *cutout plastic cup.*



Two-handed cups enable people with moderate muscle weakness to lift a cup with two hands.

People with uncontrolled or excessive movements might prefer to drink liquids from a *covered cup* or glass with a *slotted opening* or *spout.*



A soft, flexible long plastic straw may also ease the task of drinking.

hours preparing special foods, monitoring the use of adaptive feeding equipment, and helping with feedings. Moreover, a person with disabilities may need help with other tasks as well, and all may require a considerable amount of time. In many cases, a caregiver receives little or no assistance. These conditions may lead to strained interactions between caregiver and patient and cause frustration and depression.[7] Psychologists can offer counseling to patients or caregivers to help them adjust, and all members of the health care team can offer emotional support and practical suggestions to ease caregivers' responsibilities and frustrations.

Successful therapy for people with feeding disabilities requires the involvement of many health care professionals and depends on accurate identification of impaired feeding skills and determination of appropriate interventions. Ideally, with training, people with disabilities attain total independence—they are able to prepare, serve, and eat nutritionally adequate food daily without help. In some cases, these goals can be met with the help of caregivers. The combined efforts of the health care team can support both patients and caregivers in enhancing quality of life and in achieving independence to the greatest degree possible.

Nutrition in the Clinical Setting

Each bean-shaped kidney is only about the size of a fist, yet the kidneys carry out many critical functions. Among other tasks, the kidneys shoulder much of the responsibility for maintaining the body's chemical balance. If the kidneys fail to function, toxic compounds build up in the blood, causing a wide range of symptoms and life-threatening complications. Unfortunately, acute kidney diseases have high mortality rates, and chronic kidney disease is underdiagnosed and undertreated, as symptoms do not arise until the later stages. Health practitioners must learn to recognize and treat renal diseases early, before kidney damage progresses and causes irreversible illness.

CHAPTER 28

Renal Diseases

CHAPTER OUTLINE

Functions of the Kidneys

The Nephrotic Syndrome • Consequences of the Nephrotic Syndrome • Treatment of the Nephrotic Syndrome

Acute Renal Failure • Causes of Acute Renal Failure • Consequences of Acute Renal Failure • Treatment of Acute Renal Failure

Chronic Kidney Disease • Consequences of Chronic Kidney Disease • Treatment of Chronic Kidney Disease • Kidney Transplants

Kidney Stones • Formation of Kidney Stones • Consequences of Kidney Stones • Prevention and Treatment of Kidney Stones

HIGHLIGHT 28 Dialysis

The two kidneys sit just above the waist on each side of the spinal column. As part of the urinary system (see Figure 28-1 on p. 874), they are responsible for filtering blood and removing excess fluid and wastes for elimination in urine. Many body functions, including the work of the heart, blood vessels, enzymes, and cell membranes, depend on the kidneys to maintain normal fluid volume and composition. Because the kidneys are so proficient at this task, disturbances in body fluids that result from food intake, physical activity, and metabolism are normally corrected within hours. In addition, the kidneys perform a number of other metabolic roles, as discussed in the following section. Thus, **renal** disorders not only result in fluid and electrolyte imbalances, but can have widespread effects on health.

Functions of the Kidneys

The functional unit of the kidneys is the **nephron,** introduced on p. 402 (see Figure 12-2). Within each nephron, the **glomerulus,** a ball-shaped tuft of capillaries, serves as a gateway through which the components of blood must pass to form **filtrate.**◆ The glomerulus and surrounding **Bowman's capsule** function like a sieve, retaining blood cells and plasma proteins in blood while allowing fluid and small solutes to enter the nephron's system of **tubules.** As the filtrate passes through the tubules, its composition continuously changes as some of its components are reabsorbed and returned to the body via capillaries surrounding each tubule. Eventually, the remaining filtrate enters a **collecting duct** shared by several nephrons, and additional water is reabsorbed to form the final urine product. ◆ The urine travels through the ureters to the bladder for temporary storage (review Figure 28-1). By filtering the blood and forming urine, the kidneys regulate the extracellular fluid volume and osmolarity, electrolyte concentrations, and acid-base balance. They also excrete metabolic waste products such as urea and creatinine, as well as various drugs and toxins.

renal (REE-nal): pertaining to the kidneys.

nephron (NEF-ron): the functional unit of the kidneys, consisting of a glomerulus and tubules.
- **nephros** = kidney

glomerulus (gloh-MEHR-yoo-lus): a tuft of capillaries within the nephron that filters water and solutes from blood as urine production begins (plural: *glomeruli).*

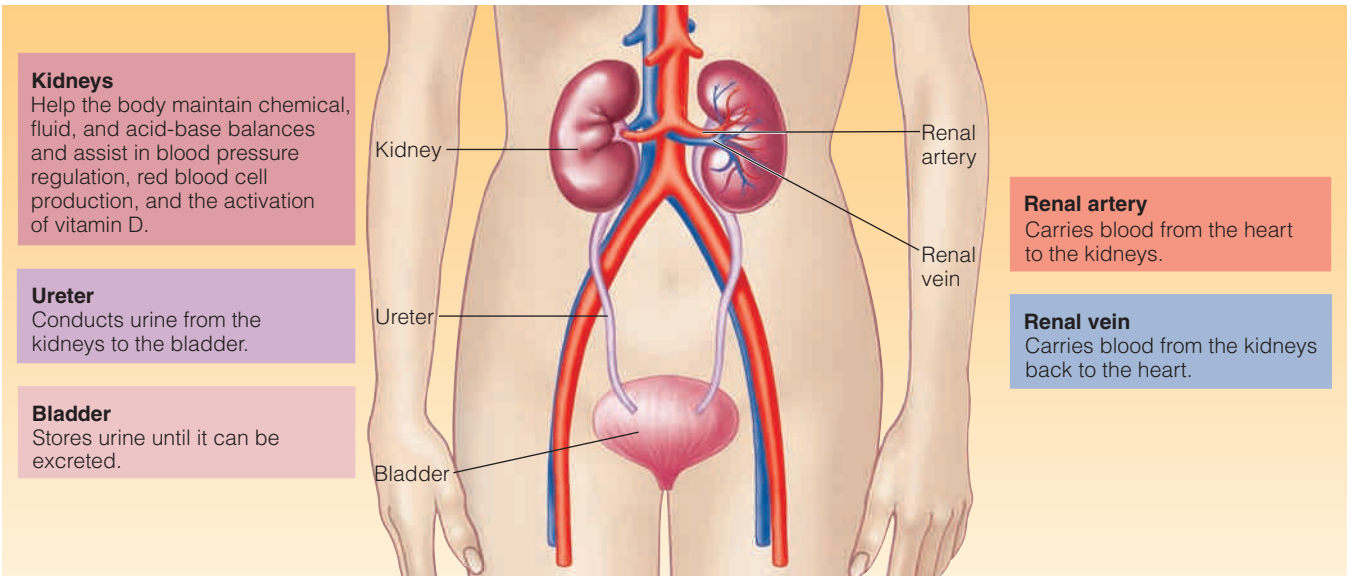
filtrate: the substances that pass through the glomerulus and travel through the nephron's tubules, eventually forming urine.

Bowman's (BOE-minz) **capsule:** a cuplike component of the nephron that surrounds the glomerulus and collects the filtrate that is passed to the tubules.

tubules: tubelike structures of the nephron that process filtrate during urine production. The tubules are surrounded by capillaries that reabsorb substances retained by tubule cells.

collecting duct: the last portion of a nephron's tubule, where the final concentration of urine occurs. One collecting duct is shared by several nephrons.

FIGURE 28-1 The Kidneys and Urinary Tract



- The rate at which the kidneys form filtrate is known as the *glomerular filtration rate,* discussed later in this chapter.
- About 99 percent of the substances in filtrate, including water, are reabsorbed, leaving only 1 to 2 liters of urine to be excreted daily.

In addition to their remarkable role in maintaining homeostasis, the kidneys have other critical roles:

- The kidneys help to regulate blood pressure by secreting the enzyme renin. Renin catalyzes the formation of angiotensin, a potent vasoconstrictor that narrows the diameters of arterioles and thereby raises blood pressure (for details, review p. 401 and Figure 12-3 on p. 403). Angiotensin also stimulates the release of aldosterone, an adrenal hormone that triggers the kidneys to reabsorb more sodium. Sodium reabsorption promotes water retention and increases plasma volume, which raises blood pressure.
- The kidneys produce the hormone **erythropoietin,** which stimulates the production of red blood cells in the bone marrow (see Highlight 19 for details).
- The kidneys convert vitamin D to its active form, 1,25-dihydroxyvitamin D_3 (see Figure 11-9 on p. 377), thereby playing a primary role in calcium regulation and bone formation.

Subsequent sections of this chapter explain how renal diseases can interfere with these kidney functions and severely disrupt health.

IN SUMMARY

The kidneys are responsible for filtering the blood and removing wastes for excretion in urine. By adjusting the blood's volume and composition, the kidneys help to maintain homeostasis within the body. Other kidney functions include the production of enzymes and hormones that regulate blood pressure, stimulate red blood cell production, and activate vitamin D.

erythropoietin (eh-RITH-ro-POY-eh-tin): a hormone made by the kidneys that stimulates red blood cell production.

nephrotic (neh-FROT-ik) **syndrome:** a syndrome associated with kidney disorders that cause urinary protein losses exceeding 3.0 to 3.5 g/day; symptoms include low serum albumin, elevated blood lipids, and edema.

proteinuria (PRO-teen-NOO-ree-ah): loss of protein, mostly albumin, in the urine; also known as *albuminuria.*

The Nephrotic Syndrome

The **nephrotic syndrome** is not a specific disease; rather, the term refers to kidney disorders that cause urinary protein losses **(proteinuria)** exceeding 3.0 to 3.5 grams per day.[1] Although the nephrotic syndrome can occur at any age, it is seen

most often in children between 1½ and 4 years of age.[2] The condition arises when damage to the glomeruli increases their permeability to plasma proteins, allowing protein to escape into the urine. Although various diseases involving the glomeruli are often the cause, the nephrotic syndrome may also be a complication of diabetes mellitus, immunological and hereditary disorders, infections (involving the kidneys or elsewhere in the body), chemical damage (from medications or illicit drugs), and some cancers. Along with proteinuria, typical clinical findings include low serum albumin levels, edema, elevated blood lipids, and blood coagulation disorders. The nephrotic syndrome can sometimes progress to renal failure.

Consequences of the Nephrotic Syndrome

In the nephrotic syndrome, urinary protein losses generally average about 8 grams daily, but additional protein is lost due to protein catabolism within the kidney tubules.[3] The liver attempts to compensate for these losses by increasing its synthesis of certain plasma proteins, but the excessive production of some of the proteins causes additional complications.

Edema Because albumin is the most abundant plasma protein, it is also the protein with the most significant loss in urine. Consequently, its blood level is markedly reduced, which contributes to a fluid shift from blood plasma to the interstitial spaces and, thus, edema. ◆ Defective sodium excretion also contributes to edema: the kidney tubules reabsorb sodium in greater amounts than usual, causing sodium and water retention within the body.[4]

◆ Reminder: Plasma proteins, such as albumin, help to maintain fluid balance within the blood.

Risk of Cardiovascular Disease People with the nephrotic syndrome frequently have elevated levels of low-density lipoproteins (LDL), very-low-density lipoproteins (VLDL), and the more damaging LDL variant known as lipoprotein(a). The impaired clearance of VLDL from blood is largely due to reduced lipoprotein lipase on the blood vessel walls.[5] ◆ The risk of blood clotting is increased in the nephrotic syndrome due to urinary losses of proteins that inhibit blood clotting and elevated levels of plasma proteins that favor clotting. These factors raise the risks of developing heart disease and stroke.[6]

◆ Reminder: *Lipoprotein lipase* is the enzyme that hydrolyzes the triglycerides in lipoproteins.

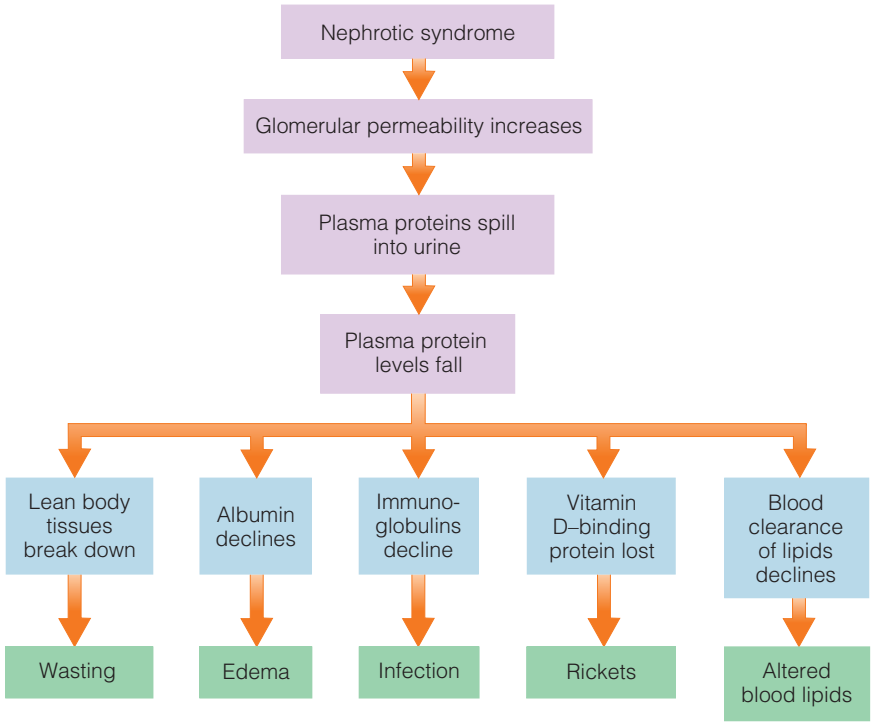
Other Effects of the Nephrotic Syndrome The proteins lost in urine include immunoglobulins (antibodies) and vitamin D–binding protein. Depletion of immunoglobulins increases susceptibility to infection. Loss of vitamin D–binding protein results in lower vitamin D and calcium levels and increases the risk of rickets in children. Patients with the nephrotic syndrome frequently develop protein-energy malnutrition (PEM) and muscle wasting from the continued proteinuria. Figure 28-2 on p. 876 summarizes the effects of urinary protein losses in the nephrotic syndrome.

Treatment of the Nephrotic Syndrome

Medical treatment of the nephrotic syndrome requires diagnosis and management of the underlying disorder responsible for the proteinuria. Complications are managed with medications and medical nutrition therapy. The drugs prescribed may include diuretics, ACE inhibitors (which reduce protein losses), lipid-lowering drugs, anticoagulants, anti-inflammatory drugs (usually corticosteroids), and immunosuppressants (such as cyclosporine).[7] Nutrition therapy helps to alleviate edema, prevent PEM, and slow the progression of atherosclerosis.

Protein and Energy Meeting protein and energy needs helps to minimize losses of muscle tissue. However, high-protein diets are not advised because they can exacerbate urinary protein losses and result in further damage to the kidneys.[8] Instead, the protein intake should fall between 0.8 and 1.0 gram per kilogram of body weight per day; at least half of the protein consumed should be from high-quality sources, such as milk products, meat, fish, poultry, eggs, and soy products. An adequate energy intake (about 35 kcalories per kilogram of body weight daily)

FIGURE 28-2 Consequences of Urinary Protein Losses in the Nephrotic Syndrome



sustains weight and spares protein. Weight loss or infections suggest the need for additional kcalories.

Fat As Chapter 27 explained, a diet low in saturated fat, *trans* fats, cholesterol, and refined sugars helps to control elevated blood lipids. Thus, patients with the nephrotic syndrome should limit saturated fat intake to 7 percent of total kcalories, avoid foods that contain *trans* fats, and limit cholesterol intake to 200 milligrams per day. Dietary measures are usually inadequate for controlling blood lipids, however, so physicians usually prescribe lipid-lowering medications as well.

Sodium and Potassium Sodium restriction helps to control edema; therefore, sodium intake is often limited to 1 to 2 grams daily.[9] Table 28-1 provides guidelines for following a diet restricted to 2 grams of sodium. If diuretics prescribed for the edema cause potassium losses, patients are encouraged to select foods rich in potassium (see Chapter 12, pp. 414–415).

Vitamins and Minerals Patients with the nephrotic syndrome may require vitamin D and calcium supplementation to help prevent bone loss and rickets. Multivitamin/mineral supplementation is often advised to avoid additional nutrient deficiencies; nutrients at risk include vitamin B_6, vitamin B_{12}, folate, iron, copper, and zinc.[10] ◆

◆ Nutrient deficiencies may develop if the carrier proteins for nutrients are lost in the urine.

IN SUMMARY

The nephrotic syndrome is characterized by urinary protein losses exceeding 3.0 to 3.5 grams per day. Complications include edema, lipid abnormalities, blood coagulation disorders, reduced immunity, rickets, and PEM. Medications treat the underlying condition and help to manage complications. The diet should provide sufficient protein and energy to maintain health, but patients should avoid consuming excess protein. Other dietary adjustments may be needed to correct edema, lipid disorders, and nutrient deficiencies.

TABLE 28-1 Sodium-Restricted Diet

General Guidelines

About 75% of sodium in a typical diet comes from processed foods, about 10% from unprocessed natural foods, and about 15% from table salt. With this in mind:

- Choose fresh foods and foods frozen or canned without added salt.
- Avoid adding salt to foods while cooking.
- Avoid adding salt to foods at the table.
- When eating out, ask that meals be prepared without salt.

Sodium in Foods

All foods contain sodium, but some contain more than others. Use the information about the average sodium contents of foods to tailor the diet to individual preferences.

Food Group	Serving Size	Sodium (mg) per Serving
Fresh meats, poultry, freshwater fish; low-sodium canned meats and fish; low-sodium peanut butter and cheese; unsalted cottage cheese, soybeans, and textured vegetable protein	1 oz	20
Regular fat-free, low-fat, and whole milk and yogurt	8 oz	120
Eggs	1	60
Fresh artichokes, beets, carrots, and celery; beet, collard, dandelion, mustard, and turnip greens	1/2 c	50
Regular canned vegetables	1/2 c	300
Regular white and whole-grain bread	1 slice	150
Butter and margarine	1 tsp	50
Salt	1/2 tsp	1000

Other Foods

These foods can be used freely or with some limits with respect to sodium, although some of these foods may need to be restricted for weight or blood lipid control:

- All fruits and fruit juices
- Low-sodium canned or frozen vegetables without added salt except those listed above; low-sodium vegetable juices
- Low-sodium bread and bread products; puffed rice and wheat and shredded wheat cereals; rice; pasta
- Soups, casseroles, and recipes made with allowed foods and ingredients
- Unsalted butter, margarine, nuts, and gravy; low-sodium mayonnaise and salad dressing; shortening
- Low-sodium catsup, mustard, Tabasco sauce, and other condiments; low-sodium baking powder

These foods and dishes prepared with them are high in sodium and should be avoided:

- Cured, canned, salted, or smoked meats, poultry, and fish such as bacon, luncheon meats, corned beef, kosher meats, and canned tuna and salmon; imitation fish products, salted textured vegetable protein, peanut butter, and nuts
- Buttermilk, regular cheeses
- Maraschino cherries; crystallized or glazed fruits; dried fruits with sodium sulfite added
- Pickles, pickled vegetables, sauerkraut, regular vegetable juices
- Instant and quick-cooking hot cereals; commercial bread products made from self-rising flour or cornmeal; salted snack foods
- Salt pork and bacon; commercial salad dressing; olives; regular gravy; catsup, baking powder, soy sauce, bouillon

A Sample Diet Restricted to 2 Grams Sodium

Using the preceding information, many diet plans that meet individual needs are possible. Using the guidelines for a heart-healthy diet, a typical plan for a day might look like this:

Food Group	Sodium (mg)
Meat, 6 oz (6 × 20 mg)	120
Milk, 3 c (3 × 120 mg)	360
Fruit, 3 servings	Negligible
Vegetables, 1/2 c vegetables with some sodium (1 × 50)	50
Vegetables, other vegetables and legumes, 2 servings	Negligible
Whole-grain bread, 4 slices (4 × 150 mg)	600
Salted margarine, 6 servings (6 × 50 mg)	300
Total	1430

Individuals can use the remainder of the sodium allowance for whatever foods they choose. The sodium content of other foods can be determined by reading food labels or using food composition tables. An individual may choose to use some (1/4 tsp) table salt or a favorite food that contains sodium.

Acute Renal Failure

In **acute renal failure,** also known as *acute kidney injury,* kidney function deteriorates rapidly, over hours or days. The loss of kidney function reduces urine output and allows nitrogenous wastes to build up in blood. The degree of renal dysfunction varies from mild to severe. With prompt treatment, acute renal failure is often reversible, although mortality rates are high, ranging from 36 to 86 percent.[11]

Causes of Acute Renal Failure

Various disorders can lead to acute renal failure, and it often develops as a consequence of severe illness, injury, or surgery. To aid in diagnosis and treatment, its causes are commonly classified as prerenal, intrinsic, or postrenal. *Prerenal* factors are those that cause a sudden reduction in blood flow to the kidneys; they often involve a severe stressor such as heart failure, shock, or blood loss. Factors that damage kidney tissue, such as infections, toxins, drugs, or direct trauma, are classified as *intrinsic* causes of acute renal failure. *Postrenal* factors are those that prevent excretion of urine due to urinary tract obstructions. Table 28-2 provides examples of specific disorders that may cause acute renal failure.

Consequences of Acute Renal Failure

A decline in renal function alters the composition of blood and urine. The kidneys may become unable to regulate the levels of electrolytes, acid, and nitrogenous wastes in the blood. Urine may be diminished in quantity or absent, leading to fluid retention. Diagnosis is often a complex task because the clinical effects can be subtle and vary according to the underlying cause of disease.

Fluid and Electrolyte Imbalances About half of patients with acute renal failure experience **oliguria,** producing less than 400 milliliters of urine per day.[12] ◆ The reduced excretion of electrolytes results in sodium retention and elevated levels of potassium, phosphate, and magnesium in the blood. Elevated potassium **(hyperkalemia)** is of particular concern, because potassium imbalances can alter heart rate and lead to heart failure. Elevated serum phosphate levels **(hyperphosphatemia)** ◆ promote an increased secretion of parathyroid hormone, leading to losses in bone calcium. Due to the sodium retention and reduced urine production, edema is a common symptom of acute renal failure and may be apparent as puffiness in the face and hands and swelling of the feet and ankles.

◆ Normal urine volume exceeds 800 milliliters per day, which is equivalent to about 27 fluid ounces, or almost $3^1/_2$ cups.

◆ To measure serum phosphate, the phosphorus content of the blood is analyzed; thus the terms *serum phosphate* and *serum phosphorus* are often used interchangeably.

acute renal failure: abrupt loss of kidney function over a period of hours or days; also known as *acute kidney injury.*

oliguria (OL-lih-GOO-ree-ah): an abnormally low amount of urine, often less than 400 mL/day.

hyperkalemia (HIGH-per-ka-LEE-me-ah): elevated serum potassium levels.

hyperphosphatemia (HIGH-per-fos-fa-TEE-me-ah): elevated serum phosphate levels.

TABLE 28-2 Causes of Acute Renal Failure

Prerenal Factors (60% to 70% of cases)	Intrinsic Factors (25% to 40% of cases)	Postrenal Factors (5% to 10% of cases)
• **Low blood volume or pressure:** Hemorrhage, burns, sepsis or shock, anaphylactic reactions, nephrotic syndrome, gastrointestinal losses, diuretics, antihypertensive medications • **Renal artery disorders:** Blood clots or emboli, stenosis, aneurysm, trauma • **Heart disorders:** Heart failure, heart attack, arrhythmias	• **Vascular disorders:** Sickle-cell disease, diabetes mellitus, transfusion reactions • **Obstructions (within kidney):** Inflammation, tumors, stones, scar tissue • **Renal injury:** Infections, environmental contaminants, drugs, medications, *Escherichia coli* food poisoning	• **Obstructions (ureter or bladder):** Strictures, tumors, stones, trauma • **Prostate disorders:** Cancer or hyperplasia • **Renal vein thrombosis** • **Bladder disorders:** Neurological conditions, bladder rupture • **Pregnancy**

Uremia As a result of impaired kidney function, nitrogen-containing waste products—blood urea nitrogen (BUN), creatinine, and uric acid—accumulate in the blood. ◆ Moreover, the tissue catabolism that accompanies illness generates more nitrogenous waste than usual. The clinical outcome, called **uremia,** includes symptoms such as fatigue, lethargy, confusion, headache, anorexia, a metallic taste in the mouth, nausea and vomiting, and diarrhea. In more serious cases, elevated blood pressure, rapid heartbeat, seizures, and delirium or coma may occur. It is sometimes difficult to distinguish the symptoms of uremia from those of the underlying illness.

◆ A progressive rise in BUN or creatinine suggests the presence of acute renal failure. Refer to Table 17-10 on p. 603 for normal laboratory values.

Treatment of Acute Renal Failure

Treatment of acute renal failure involves a combination of drug therapy, **dialysis,** ◆ and medical nutrition therapy to restore fluid and electrolyte balances and minimize blood concentrations of toxic waste products. Correcting the underlying illness is necessary to prevent further damage to the kidneys.

◆ Highlight 28 describes common dialysis procedures, including *continuous renal replacement therapy,* the approach usually used for treating acute renal failure.

In oliguric patients (those with reduced urine production), recovery from renal failure sometimes begins with a period of **diuresis,** in which large amounts of fluid are excreted. Because tubular function is minimal at this stage, electrolytes may not be sufficiently reabsorbed; consequently, both fluid depletion and electrolyte imbalances become a concern. Patients with this pattern of recovery (generally those whose renal failure is due to tubular injury) must be monitored closely in case they require fluid and electrolyte replacement.[13]

Drug Treatment in Acute Renal Failure Because kidney function is required for drug excretion, patients may need to use lower doses of their usual medications to compensate for limited urine output. Conversely, dialysis treatment may increase losses of some drugs, and doses may need to be increased. Drugs that are **nephrotoxic** (including some antibiotics and nonsteroidal anti-inflammatory drugs) must be avoided until kidney function improves.

The medications prescribed for acute renal failure depend on the underlying cause of illness and the complications that develop. For patients with edema, diuretics may be used to mobilize fluids; furosemide (Lasix) is the usual choice. Immunosuppressants may be prescribed for patients with inflammatory conditions. Patients with hyperkalemia are given potassium-exchange resins that bind potassium ions in the gastrointestinal (GI) tract, ensuring the elimination of potassium in the stool. Rapid correction of hyperkalemia requires the use of insulin, which causes a temporary shift of extracellular potassium into the cells. (Glucose must be supplied along with insulin to prevent hypoglycemia.) If acidosis is present, bicarbonate may be administered orally or intravenously.[14]

Protein and Energy Although its effects are highly variable, acute renal failure is typically a catabolic condition associated with hypermetabolism and muscle wasting. Thus, sufficient protein and energy must be ingested to preserve muscle mass. Initially, the patient may be provided with 35 kcalories per kilogram of body weight per day, while body weight is monitored to ensure that energy intake is adequate. If available, indirect calorimetry provides the best estimate of energy needs.

Protein contributes nitrogen, increasing the kidneys' workload, but intake should be sufficient to prevent negative nitrogen balance and additional wasting. Protein recommendations are influenced by kidney function, the degree of catabolism, and the use of dialysis (dialysis removes nitrogenous wastes).[15] Protein restriction to about 0.6 to 0.8 grams per kilogram of body weight per day may be necessary for patients with limited kidney function who are not treated with dialysis. Higher intakes (up to 2.0 grams per kilogram daily) may be recommended if kidney function improves or the treatment includes dialysis. Patients who are catabolic or septic typically have high protein needs, but they require dialysis to accommodate the additional nitrogen load.

uremia (you-REE-me-ah): the abnormal accumulation of nitrogen-containing substances, especially urea, in the blood; also called *azotemia* (AZE-oh-TEE-me-ah).

dialysis (dye-AH-lih-sis): a treatment that removes wastes and excess fluid from the blood after the kidneys have stopped functioning. The most common types of dialysis are *hemodialysis* and *peritoneal dialysis* (see Highlight 28).

diuresis (DYE-uh-REE-sis): increased urine production.

nephrotoxic: toxic to the kidneys.

Fluids Health practitioners can assess fluid status by monitoring weight fluctuations, blood pressure, pulse rates, and appearance of the skin and mucous membranes. Another method is to measure serum sodium concentrations: a low level of sodium often indicates excessive fluid intake, and a high level suggests inadequate intake.

Fluid balance must be restored in patients who are either overhydrated or dehydrated. Thereafter, fluid needs can be estimated by measuring urine output and adding about 500 milliliters to account for the water lost from skin, lungs, and perspiration. An individual with fever, vomiting, or diarrhea requires additional fluid. Patients undergoing dialysis can ingest fluids more freely.[16]

Electrolytes Serum electrolyte levels are monitored closely to determine appropriate electrolyte intakes. Generally, the potassium intake should be restricted to 2000 to 3000 milligrams daily. A phosphorus restriction may be necessary if hyperphosphatemia is present. In patients with oliguria, sodium may be restricted to between 1100 and 3300 milligrams per day; the sodium intake can be adjusted to match urinary sodium losses unless edema is present.[17] Patients undergoing dialysis can consume electrolytes more freely. As mentioned previously, oliguric patients who experience diuresis at the beginning of the recovery period may need electrolyte replacement to compensate for urinary losses.

Enteral and Parenteral Nutrition Some patients need enteral or parenteral nutrition support to obtain adequate energy. Enteral nutrition (tube feeding) is generally preferred over parenteral nutrition because it is less likely to cause infection and sepsis. Enteral formulas for patients with renal failure are more kcalorically dense and have lower protein and electrolyte concentrations than standard formulas. Total parenteral nutrition is necessary only if patients are severely malnourished or cannot consume food for more than 14 days.

IN SUMMARY

Acute renal failure is characterized by a rapid loss in kidney function, causing a buildup of fluid, electrolytes, and nitrogenous wastes in the blood. Acute renal failure may be caused by prerenal, intrinsic, or postrenal factors. Consequences may include oliguria, hyperkalemia, hyperphosphatemia, and uremia. If hyperkalemia develops, it can alter heart rate and lead to heart failure. Acute renal failure is treated with medications, dialysis, and dietary modifications. The accompanying Case Study checks your understanding of acute renal failure.

Chronic Kidney Disease

◆ Chronic kidney disease is also known as *chronic renal failure.*

◆ The kidneys' ability to function despite loss of nephrons is referred to as *renal reserve.*

chronic kidney disease: a kidney disease characterized by gradual, irreversible deterioration of the kidneys; also called **chronic renal failure.**

polycystic kidney disease: a hereditary disorder characterized by the formation of multiple cysts in the kidneys.

Unlike acute renal failure, in which kidney function declines suddenly and rapidly, **chronic kidney disease** ◆ is characterized by gradual, irreversible deterioration. Because the kidneys have a large functional reserve, ◆ the disease typically progresses over many years without causing symptoms. Patients are typically diagnosed late in the course of illness, after most kidney function has been lost.[18]

The most common causes of chronic kidney disease are diabetes mellitus and hypertension, which are estimated to cause 45 and 27 percent of cases, respectively.[19] Other conditions that lead to chronic kidney disease include inflammatory, immunological, and hereditary diseases that directly involve the kidneys. **Polycystic kidney disease,** characterized by the formation of multiple cysts in both kidneys, is a common hereditary condition that accounts for about 5 to 10 percent of chronic kidney disease cases.[20] Chronic kidney disease sometimes follows acute renal failure.

CASE STUDY Store Manager with Acute Renal Failure

Catherine Garber is a 42-year-old store manager admitted to the hospital's intensive care unit. She was first seen in the emergency room with severe edema, headache, nausea and vomiting, and a rapid heart rate. She reported an inability to pass more than minimal amounts of urine in the past two days. Her son, who drove her to the emergency room, reported that she had missed work for several days and seemed confused and unusually tired. Laboratory tests revealed elevated serum creatinine, BUN, and potassium levels. After learning from her medical history that Mrs. Garber had begun taking penicillin earlier in the week, the physician diagnosed acute renal failure, probably caused by a reaction to the medication. Mrs. Garber is 5 feet 3 inches tall and weighs 125 pounds.

1. Describe the probable reason for Mrs. Garber's inability to produce urine. Is her reaction to penicillin considered a prerenal, intrinsic, or postrenal cause of renal failure? Give examples of other medical problems that can cause acute renal failure.
2. What medications can the physician prescribe to treat Mrs. Garber's edema and hyperkalemia? What recommendation is likely regarding her continued use of penicillin?
3. What concerns should be kept in mind when determining Mrs. Garber's energy, protein, fluid, and electrolyte needs during acute renal failure? How would dialysis treatment alter recommendations?
4. After treatment begins, Mrs. Garber suddenly begins producing copious amounts of urine. How should this development alter dietary treatment?

As you read through the discussion of chronic kidney disease, consider how Mrs. Garber's diet should change if her kidney problems become chronic.

Consequences of Chronic Kidney Disease

In the early stages of chronic kidney disease, the nephrons compensate by enlarging so that they can handle the extra workload. As the nephrons deteriorate, however, there is additional work for the remaining nephrons. The overburdened nephrons continue to degenerate until finally the kidneys are unable to function adequately, resulting in kidney failure. Once the extent of kidney damage necessitates active treatment—either dialysis or a kidney transplant—the condition is classified as **end-stage renal disease (ESRD).** Without intervention at this stage, an individual cannot survive. Table 28-3 lists the common clinical effects of the early and advanced stages of chronic kidney disease. Symptoms of chronic kidney disease may not appear until over 75 percent of kidney function is lost.[21]

Renal disease is evaluated using the **glomerular filtration rate (GFR),** the rate at which the kidneys form filtrate. The GFR can be estimated using predictive equations that are based on serum creatinine levels, ◆ age, gender, race, and body size. Table 28-4 shows how chronic kidney disease is classified according to estimated GFR. Other laboratory measures used to assess kidney function include urinary protein levels, BUN, and the ratio of albumin to creatinine in a urine sample.[22]

TABLE 28-3 Clinical Effects of Chronic Kidney Disease

Early Stages

- Anorexia
- Fatigue
- Headache
- Hypertension
- Itching
- Kidney inflammation or nephrotic syndrome
- Nausea and vomiting
- Proteinuria, hematuria (blood in urine)

Advanced Stages

- Anemia, bleeding tendency
- Cardiovascular disease
- Confusion, mental impairments
- Electrolyte abnormalities
- Fluid retention
- Hormonal abnormalities
- Metabolic acidosis
- Peripheral neuropathy
- Protein-energy malnutrition
- Reduced immunity
- Renal osteodystrophy

◆ Reminder: *Creatinine* is a waste product of creatine, a nitrogen-containing compound in muscle cells.

TABLE 28-4 Evaluation of Chronic Kidney Disease

Stage of Disease	Description	GFR[a] (mL/min per 1.73 m^2)
1	Kidney damage with normal or increased GFR	≥90
2	Kidney damage with mildly decreased GFR	60–89
3	Moderately decreased GFR	30–59
4	Severely decreased GFR	15–29
5	Kidney failure	<15 (or undergoing dialysis)

[a]Glomerular filtration rate, or GFR, is estimated from the Modification of Diet in Renal Disease study equation and is based on age, gender, race, and calibration for serum creatinine. Normal GFR is approximately 125 mL/min.
SOURCE: A. S. Levey and coauthors, National Kidney Foundation practice guidelines for chronic kidney disease: Evaluation, classification, and stratification, *Annals of Internal Medicine* 139 (2003): 137–147.

end-stage renal disease (ESRD): an advanced stage of chronic kidney disease in which dialysis or a kidney transplant is necessary to sustain life.

glomerular filtration rate (GFR): the rate at which filtrate is formed within the kidneys, normally approximately 125 mL/min.

◆ Reminder: *Aldosterone* promotes sodium (and therefore water) retention and potassium excretion.

◆ Reminder: *Parathyroid hormone* helps to regulate serum concentrations of calcium and phosphorus. Elevated parathyroid hormone stimulates bone turnover and the release of calcium from bone into blood.

Altered Electrolytes and Hormones Fluid and electrolyte disturbances may not develop until the third or fourth stage of chronic kidney disease (see Table 28-4).[23] As GFR falls, the increased activity by the remaining nephrons is often sufficient to maintain electrolyte excretion. A number of hormonal adaptations also help to regulate electrolyte levels, but these changes may cause complications of their own. The increased secretion of aldosterone ◆ helps to prevent increases in serum potassium but contributes to the development of hypertension (in patients who were not previously hypertensive). Increased secretion of parathyroid hormone ◆ helps to prevent elevations in serum phosphorus but contributes to bone loss and the development of **renal osteodystrophy,** a bone disorder common in renal patients. Electrolyte imbalances are likely when GFR becomes extremely low (less than 5 milliliters per minute), when hormonal adaptations are inadequate, or when intakes of water and electrolytes are either very restricted or excessive.

Because the kidneys are responsible for maintaining acid-base balance, acidosis often develops in chronic kidney disease. Although usually mild, the acidosis exacerbates renal bone disease because compounds in bone (for example, protein and phosphates) are released to buffer the acid in blood.

Uremic Syndrome Uremia usually develops during the final stages of chronic renal failure, when GFR is below 15 milliliters per minute and BUN exceeds 60 milligrams per deciliter.[24] The many symptoms and complications that develop during this stage of illness are collectively known as the **uremic syndrome.** The uremia itself can cause subtle mental dysfunctions and neuromuscular changes such as muscle cramping, twitching, and restless leg syndrome. Other complications include:

- *Impaired hormone synthesis.* Diseased kidneys are unable to produce erythropoietin, causing anemia. Reduced production of active vitamin D contributes to bone disease.
- *Impaired hormone degradation.* Imbalances develop in hormones involved in growth, reproduction, fluid balance, blood glucose regulation, and nutrient metabolism.
- *Bleeding abnormalities.* Defects in platelet function and clotting factors prolong bleeding time and contribute to bruising, gastrointestinal bleeding, and anemia.
- *Increased cardiovascular disease risk.* Chronic kidney disease worsens risk factors such as hypertension, insulin resistance, and homocysteinemia. Elevated parathyroid hormone levels lead to calcification of blood vessels and heart tissue. Patients are at increased risk of stroke, heart attack, and heart failure.
- *Reduced immunity.* Patients with uremia have poor immune responses and are at high risk of developing infections, which are a frequent cause of death.

Protein-Energy Malnutrition Patients with chronic kidney disease often develop PEM and wasting. Clinical studies have suggested that renal patients may have inadequate protein and energy intakes, even during the early stages of disease.[25] Anorexia is thought to contribute to poor food intake and may result from hormonal disturbances, nausea and vomiting, restrictive diets, uremia, and medications. Nutrient losses also contribute to malnutrition and may be a consequence of vomiting, diarrhea, gastrointestinal bleeding, and dialysis. In addition, many of the illnesses that lead to chronic kidney disease can induce a catabolic state that contributes to protein losses.[26]

renal osteodystrophy: a bone disorder that develops in patients with chronic kidney disease as a consequence of increased secretion of parathyroid hormone, reduced serum calcium, acidosis, and impaired vitamin D activation by the kidneys.

uremic syndrome: the cluster of symptoms associated with a GFR below 15 mL/min, including uremia, anemia, bone disease, hormonal imbalances, bleeding impairment, increased cardiovascular disease risk, and reduced immunity.

Treatment of Chronic Kidney Disease

The goals of treatment for patients with chronic kidney disease are to slow disease progression and prevent or alleviate symptoms. Dietary measures help to prevent

PEM and weight loss. Once kidney disease reaches the final stages, dialysis or a kidney transplant is necessary to sustain life.

Drug Therapy for Chronic Kidney Disease Drug therapies help to control some of the complications associated with chronic kidney disease. Treatment of hypertension is critical for slowing disease progression and reducing cardiovascular disease risk; thus antihypertensive drugs are usually prescribed (see Chapter 27). Some antihypertensive drugs (such as ACE inhibitors) can reduce proteinuria, helping to prevent additional kidney damage. Anemia is usually treated by injection or intravenous administration of erythropoietin (epoetin). Other common drug treatments include the administration of phosphate binders (taken with food) to reduce serum phosphorus levels, sodium bicarbonate to reverse acidosis, and cholesterol-lowering medications. Supplementation with active vitamin D (called *calcitriol)* helps to raise serum calcium and reduce parathyroid hormone levels.

Dialysis Dialysis replaces kidney function by removing excess fluid and wastes from the blood. In **hemodialysis,** the blood is circulated through a **dialyzer** (artificial kidney), where it is bathed by a **dialysate,** a solution that selectively removes fluid and wastes. In **peritoneal dialysis,** the dialysate is infused into a person's peritoneal cavity, and blood is filtered by the peritoneum (the membrane that surrounds the abdominal cavity). After several hours, the dialysate is drained, removing unneeded fluid and wastes. Highlight 28 provides additional information about dialysis.

Medical Nutrition Therapy for Chronic Kidney Disease The patient's diet strongly influences disease progression, the development of complications, and serum levels of nitrogenous wastes and electrolytes. Because the dietary measures for chronic kidney disease are complex and nutrient needs change frequently during the course of illness, a dietitian who specializes in renal disease is best suited to provide medical nutrition therapy. Table 28-5 summarizes the dietary guidelines for patients in the different stages of chronic kidney disease. The predialysis guidelines apply to patients in stages 1 through 4; by stage 5, either hemodialysis or peritoneal dialysis is necessary. Because patients' needs can vary considerably, actual recommendations should be based on the results of a nutrition assessment.

hemodialysis (HE-moe-dye-AL-ih-sis): a treatment that removes fluids and wastes from the blood by passing the blood through a dialyzer.

dialyzer (DYE-ah-LYE-zer): a machine used in hemodialysis to filter the blood; also called an *artificial kidney.*

dialysate (dye-AL-ih-sate): the solution used in dialysis to draw wastes and fluids from the blood.

peritoneal (PEH-rih-toe-NEE-al) **dialysis:** a treatment that removes fluids and wastes from the blood by using the peritoneal membrane as a filter.

TABLE 28-5 Dietary Recommendations for Chronic Kidney Disease

Nutrient	Predialysis	Hemodialysis	Peritoneal Dialysis
Energy[a] (kcal/kg body weight)	35 for <60 years old 30–35 for ≥60 years old	35 for <60 years old 30–35 for ≥60 years old	35 for <60 years old 30–35 for ≥60 years old (total kcalories should include those absorbed from the dialysate)
Protein (g/kg body weight)	0.60–0.75 (≥50% high-quality proteins)	≥1.2 (≥50% high-quality proteins)	≥1.2–1.3 (≥50% high-quality proteins)
Fat	As necessary to maintain a healthy lipid profile	As necessary to maintain a healthy lipid profile	As necessary to maintain a healthy lipid profile
Fluid (mL/day)	Unrestricted if urine output is normal	1000 plus urine output	As necessary to maintain fluid balance
Sodium (mg/day)	1000–3000	1000–3000	2000–4000
Potassium (mg/day)	Unrestricted unless hyperkalemia is present	2000–3000; adjust according to serum potassium levels	3000–4000; adjust according to serum potassium levels
Calcium (mg/day)	1000–1500	≤2000 from diet and medications	≤2000 from diet and medications
Phosphorus (mg/day)	800–1000 if serum phosphorus or parathyroid hormone is elevated	800–1000 if serum phosphorus or parathyroid hormone is elevated	800–1000 if serum phosphorus or parathyroid hormone is elevated

[a]Values listed apply to adults; recommendations for children should not fall below DRI levels.
SOURCE: National Kidney Foundation

Energy The energy intake should be high enough to allow patients to maintain a healthy weight and to prevent wasting. Foods and beverages with high energy density are typically recommended. ◆ Malnourished patients may require oral supplements or tube feedings to maintain weight.

◆ Reminder: Foods with high energy density contain a high number of kcalories per unit weight; these foods are generally high in fat and low in water content.

Patients undergoing peritoneal dialysis can absorb a substantial amount of glucose from the dialysate, which can contribute as many as 800 kcalories daily. ◆ These kcalories must be included in estimates of energy intake. Weight gain is sometimes a problem when peritoneal dialysis continues for a long period.

◆ The dialysate contains glucose in order to draw fluid from the blood to the peritoneal cavity by osmosis.

Protein A low-protein diet is usually prescribed to help slow the progression of kidney disease. During the predialysis period, the recommended protein intake is 0.60 to 0.75 grams per kilogram of body weight per day.[27] ◆ Low-protein diets produce fewer nitrogenous wastes and therefore reduce the risk of uremia. In addition, low-protein diets supply less phosphorus than high-protein diets, reducing the risks associated with hyperphosphatemia. Low-protein breads, pastas, and other grain-based products are commercially available to help renal patients improve their energy intakes without increasing protein consumption.

◆ The protein RDA for adults is 0.8 g/kg body weight.

Because renal patients often develop PEM, however, their diet must provide enough protein to meet needs and prevent wasting. Therefore, at least 50 percent of the protein consumed should be from high-quality protein sources (such as eggs, milk products, meat, poultry, fish, and soybeans) to ensure that the patient consumes adequate amounts of the essential amino acids.

Because of the high risk of wasting and compliance difficulties associated with low-protein diets, some dietitians suggest that patients consume higher amounts of protein to preserve health.[28] Another option is to encourage patients to undergo a resistance training program, which can improve protein utilization, nitrogen retention, and muscle strength despite adherence to a low-protein diet.[29] Once dialysis has begun, protein restrictions can be relaxed, because dialysis removes nitrogenous wastes and results in some amino acid losses as well.

Lipids Patients with chronic kidney disease are at increased risk of coronary heart disease and are therefore advised to restrict their intakes of saturated fat, *trans* fat, and cholesterol to help control elevated blood lipids. Although patients are often encouraged to consume high-fat foods to improve their energy intakes, the foods they select should provide mostly unsaturated fats; good choices include nuts and seeds, oil-based salad dressings, mayonnaise, ◆ avocados, and soybean products (Highlight 5 provides additional suggestions).

◆ Reminder: Most salad dressings and mayonnaise products are made with polyunsaturated or monounsaturated vegetable oils.

Sodium and Fluids As kidney disease progresses, the patient excretes less urine and cannot handle normal intakes of sodium and fluids. Recommendations depend on the total urine output, changes in body weight and blood pressure, and serum sodium levels. A rise in body weight and blood pressure suggests that the person is retaining sodium and fluid; conversely, declines in these measurements indicate fluid loss. Most people with kidney disease tend to retain sodium and may benefit from mild restriction; less frequently, a patient may have a salt-wasting condition that requires additional dietary sodium.

© Craig M. Moore

In a renal diet, at least half of the protein consumed should be from high-quality sources such as eggs, milk, meat, poultry, and fish.

Fluids are not restricted until urine output decreases. For a person who is neither dehydrated nor overhydrated, the daily fluid intake should match the daily urine output. (Obligatory water losses—from skin and lungs—are replaced from the water contained in solid foods.) Once a person is on dialysis, sodium and fluid intakes should be controlled so that only about 2 pounds of water weight is gained daily—this excess fluid is then removed during the next dialysis treatment.[30] Patients on fluid-restricted diets should be advised that foods such as flavored gelatin, soups, fruit ices, frozen fruit juice bars, and ice milk contribute to the fluid allowance.

Potassium Before dialysis treatments begin, most renal patients can handle typical intakes of potassium. Potassium restrictions are usually necessary only in patients with elevated potassium levels. Individuals with diabetic nephropathy are at high risk of hyperkalemia and may need to limit dietary potassium during

the early stages of disease. Conversely, potassium supplementation may be necessary for persons using potassium-wasting diuretics.

Dialysis patients must control potassium intakes to prevent hyperkalemia or, more rarely, **hypokalemia.** Restriction is usually necessary for people treated with hemodialysis, whereas those undergoing peritoneal dialysis can consume potassium more freely. Recommended intakes are based on serum potassium levels, renal function, medications, and the dialysis procedure used.

All fresh foods provide potassium, but some fruits and vegetables contain such high amounts that their regular use is discouraged in patients at risk of hyperkalemia; examples include avocados, bananas, beets, brussels sprouts, chard, dates, dried beans and peas, dried fruit, honeydew melon, nectarines, oranges, potatoes, spinach, sweet potatoes, tomatoes, winter squash, and zucchini.[31] Foods in other food groups that are high in potassium include milk and milk products, molasses, and nuts; patients with potassium restrictions must limit these foods as well. Individuals with renal failure should be cautioned that salt substitutes and other low-sodium products often contain potassium chloride, which people on a potassium-restricted diet should avoid. Appendix H provides additional information about the potassium content of common foods.

© Craig M. Moore

People on a renal diet can consume most fruits and vegetables in limited amounts.

Calcium, Phosphorus, and Vitamin D To prevent bone disease, calcium and phosphorus intakes may need adjustment, even during the early stages of kidney disease. Laboratory values usually help to guide dietary recommendations for these nutrients. Serum calcium levels must be monitored to guard against **hypercalcemia,** which can develop in response to simultaneous calcium and vitamin D supplementation. Elevated serum phosphorus levels indicate the need for dietary phosphorus restriction. Vitamin D supplementation is standard treatment for many renal patients, ◆ but the amount prescribed depends on the serum levels of calcium, phosphorus, and parathyroid hormone.

◆ Reminder: Diseased kidneys are unable to produce activated vitamin D, which normally regulates calcium absorption and helps to maintain serum calcium levels.

High-protein foods are also high in phosphorus, so the protein-restricted diets consumed by predialysis patients curb phosphorus intakes as well. After dialysis treatments begin and protein intakes are liberalized, phosphate binders (taken with meals) become essential for phosphorus control. Because foods that are rich in calcium (such as milk and milk products) are usually high in phosphorus and are therefore restricted, patients must rely on calcium supplements to meet their calcium needs.

Vitamins and Minerals The restrictive renal diet interferes with vitamin and mineral intakes, increasing the risk of deficiencies. In addition, patients treated with dialysis lose water-soluble vitamins and some trace minerals into the dialysate. Dietary supplements for renal patients typically supply generous amounts of folate and vitamin B_6—1 milligram and 10 milligrams per day, respectively—along with recommended amounts of the other water-soluble vitamins. Supplemental vitamin C should be limited to 100 milligrams per day, because excessive intakes can contribute to kidney stone formation in individuals at risk (see p. 889). Supplements containing vitamins A and E are not recommended because these vitamins sometimes accumulate in patients with renal disease.[32]

Iron deficiency is common in hemodialysis patients and may be due to inadequate erythropoietin, gastrointestinal bleeding, reduced iron absorption, or blood losses associated with the dialysis treatment.[33] Intravenous administration of iron, in conjunction with erythropoietin therapy, is more effective than oral iron supplementation for improving iron status.

Enteral and Parenteral Nutrition Enteral and parenteral nutrition support can provide nutrients to renal patients who cannot consume adequate amounts of food. The enteral formulas suitable for chronic kidney disease are more kcalorically dense and have lower protein and electrolyte concentrations than standard formulas. **Intradialytic parenteral nutrition** is an option for supplying supplemental nutrients to dialysis patients; this technique combines parenteral

hypokalemia (HIGH-po-ka-LEE-me-ah): low serum potassium levels.

hypercalcemia (HIGH-per-kal-SEE-me-ah): elevated serum calcium levels.

intradialytic parenteral nutrition: the infusion of nutrients during hemodialysis, often providing amino acids, dextrose, lipids, and some trace minerals.

feedings with hemodialysis treatments. An advantage of this approach is that the volume of parenteral solution infused can be simultaneously removed (recall that fluid intake is controlled in dialysis patients). However, clinical studies have not shown intradialytic parenteral nutrition to be more successful than oral supplementation in improving nutrition status or mortality rates in malnourished dialysis patients.[34]

Dietary Compliance Adhering to a renal diet is probably the most difficult aspect of treatment for patients with renal disease. These patients often require extensive counseling once multiple dietary restrictions become necessary. Depending on the stage of illness and the patient's laboratory values, the renal diet may limit protein, fluids, sodium, potassium, and phosphorus, thereby affecting food selections from all major food groups. Because these diets have so many restrictions, patient compliance is often a problem.[35] The "How to" below provides suggestions to help patients comply with renal diets. The accompanying Case Study allows you to apply your knowledge about chronic kidney disease and hemodialysis.

Kidney Transplants

A preferred alternative to dialysis in patients with end-stage renal disease is kidney transplantation.[36] A successful kidney transplant restores kidney function, allows a more liberal diet, and frees the patient from routine dialysis. Given the choice, many patients would prefer transplants, but the demand for suitable kidneys far exceeds the supply. Other barriers to transplantation include advanced age, poor health, financial difficulties, and abnormalities of the urinary tract. Fewer than 20 percent of patients who develop end-stage renal disease receive a kidney transplant.[37]

Immunosuppressive Drug Therapy To prevent tissue rejection following transplant surgery, patients require high doses of immunosuppressive drugs such as corticosteroids, cyclosporine, tacrolimus, sirolimus, and azathioprine. These drugs have multiple effects that can alter nutrition status, including nausea, vomiting, diarrhea, glucose intolerance, altered blood lipids, fluid retention, hypertension,

HOW TO Help Patients Comply with a Renal Diet

Patients with renal disease and their caregivers face considerable challenges as they learn to manage a renal diet. The following suggestions may help:

1. *To keep track of fluid intake:*
   - Fill a container with an amount of water equal to your total fluid allowance. Each time you use a liquid food or beverage, discard an equivalent amount of water from the container. The amount remaining in the container will show you how much fluid you have left for the day.
   - Be sure to save enough fluid to take medications.
2. *To help control thirst:*
   - Chew gum or suck hard candy.
   - Freeze beverages to a semisolid state so that they take longer to consume.
   - Add lemon juice or crumpled mint leaves to water to make it more refreshing.
   - Gargle with refrigerated mouthwash.
3. *To increase the energy content of meals:*
   - Add extra margarine or butter to rice, noodles, breads, crackers, and cooked vegetables. Add extra salad dressing or oil to salads.
   - Add nondairy whipped toppings to desserts.
   - Include fried foods in your diet.
4. *To include more of your favorite vegetables in meals:*
   - Consult your dietitian or nurse to learn whether you can safely use the process of leaching to remove some of the potassium from vegetables.
   - To leach potassium from vegetables: Cut the vegetables into $^1/_8$-inch slices and rinse. Soak the vegetables in a large amount of warm water for two hours—about ten parts of water to one part of vegetables. Cook the vegetables using five parts of water to one part of vegetables.
5. *To prevent the diet from becoming monotonous:*
   - Experiment with new combinations of allowed foods.
   - Substitute nondairy products for milk products. Nondairy products, which are lower in protein, phosphorus, and potassium, can substitute for milk and add energy to the diet.
   - Add flavor to foods by seasoning with garlic, onion, chili powder, curry powder, oregano, mint, basil, parsley, pepper, or lemon juice.
   - Consult a dietitian or nurse when you want to eat restricted foods. Many restricted foods can be used occasionally and in small amounts if the menu is carefully adjusted.

CASE STUDY Banker with Chronic Kidney Disease

Thomas Stone is a 55-year-old banker who developed chronic kidney disease as a result of hypertension. His condition was discovered several years ago, when routine laboratory tests revealed elevated serum creatinine and BUN levels. Since then, he has been taking antihypertensive medications and restricting dietary sodium; he reported difficulty following the low-protein diet that was also prescribed. Mr. Stone recently visited his doctor with complaints of low urine output and reduced sensation in his hands and feet. He also reported feeling drowsy at work and mentioned that he was bruising more than usual. The examination revealed a 9-pound weight gain since his last visit and swelling in his ankles and feet. Tests revealed that his GFR had fallen to 10 milliliters per minute. Mr. Stone is 5 feet 8 inches tall and normally weighs 160 pounds.

1. Explain how chronic kidney disease progresses. What happens to GFR, serum creatinine levels, and BUN as renal function declines?
2. Describe the clinical effects you would expect during the final stage of disease, when kidney failure develops. Explain the significance of each of Mr. Stone's physical complaints.
3. Explain why a low-sodium, low-protein diet was prescribed for Mr. Stone at a former visit. What energy and protein intakes were probably recommended at that time?
4. The physician determines that Mr. Stone's kidney disease has reached the final stage and prescribes hemodialysis. How will dialysis alter Mr. Stone's diet? Calculate his new protein recommendation, and compare it to the amount of protein recommended before dialysis. What other changes in nutrient intake may be necessary?

and infection. Because immunosuppressive drug therapy increases the risk of foodborne infection, food safety guidelines should be provided to patients and caregivers. The Diet-Drug Interactions feature summarizes the nutrition-related effects of immunosuppressants and other drugs mentioned in this chapter.

DIET-DRUG INTERACTIONS

Check this table for notable nutrition-related effects of the medications discussed in this chapter.

	Gastrointestinal Effects	Interactions with Dietary Substances	Metabolic Effects
Anti-inflammatory/ immunosuppressive drugs			
Corticosteroids	—	—	Glucose intolerance, sodium retention, negative nitrogen balance, appetite stimulation, weight gain, growth suppression in children.
Cyclosporine	—	Grapefruit juice raises drug levels and increases risk of toxicity. Avoid potassium supplements and salt substitutes with potassium. St. John's wort can alter drug efficacy.	Hyperkalemia, hypomagnesia, hyperglycemia, hyperlipidemia.
Phosphate binders (calcium containing)	Constipation.	—	Electrolyte imbalances.
Potassium-exchange resins (sodium polystyrene sulfonate)	—	—	Fluid retention, hypokalemia, hypocalcemia.
Potassium citrate	Nausea, vomiting, stomach pain, diarrhea.	—	Hyperkalemia.

TABLE 28-6 Dietary Guidelines Following a Kidney Transplant

- **Energy:** Initially, 30–35 kcal/kg body weight per day; reduce to 25–30 kcal/kg body weight per day to maintain healthy body weight, and adjust as necessary.
- **Protein:** Initially, 1.3 to 1.5 g/kg body weight per day; reduce to 1.0 g/kg per day after 6–8 weeks.
- **Carbohydrate:** For hyperglycemia, maintain consistent carbohydrate intake at meals and snacks.
- **Fat:** Limit saturated fat (to <10% of total kcalories) and cholesterol (to <300 mg/day) to help control serum lipids.
- **Sodium:** Generally unrestricted. Restrict to 2–4 g/day if fluid retention and hypertension are present.
- **Potassium:** Generally unrestricted. Adjust according to serum potassium levels if necessary.
- **Calcium:** 1200 mg/day to minimize bone loss associated with drug therapy.
- **Phosphorus:** Unrestricted.
- **Fluid:** Unrestricted.

SOURCE: J. A. Beto and V. K. Bansal, Medical nutrition therapy in chronic kidney failure: Integrating clinical practice guidelines, *Journal of the American Dietetic Association* 104 (2004): 404–409.

Nutrition Therapy after Kidney Transplant Protein and energy requirements increase after surgery due to stress and the catabolic effects of drug therapy. Once recovery is under way, the side effects of drugs can strongly influence dietary treatment. Typical dietary modifications are shown in Table 28-6.[38] Hyperglycemia (due to drug treatment) may be improved by controlling carbohydrate intake, although oral medications or insulin therapy may also be required. Because blood lipids are frequently elevated, patients should limit saturated fat and cholesterol intakes. Sodium, potassium, and phosphorus intakes are often liberalized following a transplant, but serum electrolyte levels must be monitored closely because some drug therapies can cause hyperkalemia or hypophosphatemia. Calcium supplementation is advised due to urinary calcium losses associated with corticosteroids (which are often used as immunosuppressants). To avoid foodborne illness, patients should avoid raw or undercooked meat, fish, poultry, and eggs; unpasteurized milk and juices; cheese made with unpasteurized milk; fresh bean sprouts; and food that is spoiled or moldy.[39]

IN SUMMARY

Chronic kidney disease causes gradual loss of kidney function and often results from long-standing diabetes mellitus or hypertension. Depending on the stage of chronic kidney disease, its complications may include fluid and electrolyte disturbances, hypertension, renal osteodystrophy, mental impairments, bleeding abnormalities, anemia, increased risk for cardiovascular disease, and reduced immunity. Treatment can slow disease progression and correct complications; it includes drug therapies, dialysis, and medical nutrition therapy. Dietary measures usually feature a low-protein diet, controlled fluid and sodium intakes, phosphorus restrictions, and calcium and vitamin D supplementation; potassium restrictions are usually necessary after dialysis treatment begins. Kidney transplantation can restore renal function and liberalize dietary restrictions.

Kidney Stones

Approximately 12 percent of men and 6 percent of women in the United States develop one or more **kidney stones** during their lifetimes.[40] A kidney stone is a crystalline mass that forms within the urinary tract. Although stones are often asymptomatic, their passage can cause severe pain or block the urinary tract. Stones tend to recur but can be prevented with dietary measures and medical treatment.

kidney stones: crystalline masses that form in the urinary tract; also called *renal calculi* and *nephrolithiasis.*

Formation of Kidney Stones

Kidney stones develop when stone constituents become concentrated in urine, allowing crystals to form and grow. About 70 percent of kidney stones are made up primarily of calcium oxalate. Less commonly, stones are composed of uric acid, the amino acid cystine, calcium phosphate, or magnesium ammonium phosphate (the latter are known as *struvite* stones). Factors that predispose an individual to stone formation include the following:

- *Dehydration* or *low urine volume,* which promotes the crystallization of minerals and other compounds in urine.
- *Obstruction,* which prevents the flow of urine and encourages salt precipitation.
- *Urine acidity,* which affects the dissolution of urinary constituents. Some stones form more readily in acidic urine, whereas others form in alkaline urine.
- *Metabolic factors,* which affect the presence of compounds that either promote or inhibit crystal growth.
- *Renal disease,* which is associated with calcification of tissues and phosphate accumulation.

Dr. M.A. Ansary/Photo Researchers, Inc.

The most common type of kidney stone is composed of calcium oxalate crystals, as shown here.

The most common types of kidney stones are described in this section.

Calcium Oxalate Stones The most common abnormality in people with calcium oxalate stones is **hypercalciuria** (elevated urinary calcium levels). Hypercalciuria can result from excessive calcium absorption, impaired calcium reabsorption in kidney tubules, or elevated serum levels of parathyroid hormone or vitamin D. However, some people with calcium oxalate stones excrete normal amounts of calcium in the urine, and the reason they form stones is unknown.

Elevated urinary oxalate levels, or **hyperoxaluria,** also promote the formation of calcium oxalate crystals. Oxalate is a normal product of metabolism that readily binds to calcium. Hyperoxaluria may reflect an increase in the body's synthesis of oxalate or increased absorption from dietary sources. ◆ People who form calcium oxalate stones are advised to reduce their dietary intake of oxalate (see Table 28-7 on p. 890) and to avoid supplementation with vitamin C, which degrades to oxalate in the body.[41]

◆ Reminder: Fat malabsorption promotes oxalate absorption, thereby increasing the risk of forming calcium oxalate stones (see Chapter 24).

Uric Acid Stones Uric acid stones develop when the urine is abnormally acidic, contains excessive uric acid, or both. These stones are frequently associated with **gout,** a metabolic disorder characterized by elevated uric acid levels in the blood and urine. Other diseases that increase the risk of uric acid stones include leukemia, lymphoma, and glycogen storage disease: these conditions are associated with the overproduction of **purines,** which degrade to uric acid in the body. A diet rich in purines also contributes to high uric acid levels (see Table 28-8 on p. 890).

Cystine and Struvite Stones Cystine stones can form in people with the inherited disorder **cystinuria,** in which the renal tubules are unable to reabsorb the amino acid cystine. The abnormality results in abnormally high concentrations of cystine in the urine, leading to subsequent crystallization and stone formation. **Struvite** stones, composed primarily of magnesium ammonium phosphate, form in alkaline urine as a result of the bacterial degradation of urea to ammonia. The ammonia elevates urinary pH to a level that favors struvite formation. Struvite stones can accompany chronic urinary infections or disorders that interfere with urinary flow.

hypercalciuria (HIGH-per-kal-see-YOO-ree-ah): elevated urinary calcium levels.

hyperoxaluria (HIGH-per-ox-ah-LOO-ree-ah): elevated urinary oxalate levels.

gout (GOWT): a metabolic disorder characterized by elevated uric acid levels in the blood and urine and the deposition of uric acid in and around the joints, causing acute joint inflammation.

purines (PYOO-reens): products of nucleotide metabolism that degrade to uric acid.

cystinuria (SIS-tin-NOO-ree-ah): an inherited disorder characterized by elevated urinary excretion of several amino acids, including cystine.

struvite (STROO-vite): crystals of magnesium ammonium phosphate.

renal colic: the intense pain that occurs when a kidney stone passes through the ureter.

Consequences of Kidney Stones

In most cases, kidney stones do not pose serious medical problems. Small stones can readily pass through the ureters and out of the body with minimal treatment.

Renal Colic A stone passing through the ureter can produce severe, stabbing pain, called **renal colic.** Generally, the pain begins in the back and intensifies as

TABLE 28-7 Foods High in Oxalate

Vegetables	Fruits	Other
Beans, green and wax	Blackberries	Chocolate and chocolate beverages*
Beets*	Blueberries	Cocoa
Celery	Currants, red	Coffee
Chard, Swiss	Gooseberries	Draft beer
Collard greens	Grapes, Concord	Fruitcake
Dandelion greens	Lemon peel	Grits
Eggplant	Lime peel	Nuts, nut butters*
Endive	Orange peel	Peanut butter*
Escarole	Raspberries	Pepper
Leeks	Rhubarb*	Soybean crackers
Legumes	Strawberries*	Tea*
Okra		Tofu
Parsley		Wheat bran*
Potatoes, sweet		Wheat germ
Spinach*		
Squash, summer		

NOTE: The oxalate content of many foods has not been analyzed, and even fewer studies have been conducted to determine which foods raise urinary oxalate levels. * The foods marked with an asterisk have been documented to raise urinary oxalate levels and should be avoided by people who form calcium stones.

TABLE 28-8 Foods High in Purines

Organ Meats	Meat and Meat Products	Seafood
Brains	Game meat	Anchovies
Kidney	Gravies	Herring
Liver	Meat extracts	Mackerel
Sweetbreads		Sardines
		Scallops

the stone travels toward the bladder (review Figure 28-1 on p. 874). The pain can be severe enough to cause nausea and vomiting and sometimes requires medication. When the stone reaches the bladder, the pain abruptly stops. Blood may appear in the urine **(hematuria)** as a result of damage to the kidney or ureter lining.

hematuria (HE-mah-TOO-ree-ah): blood in the urine.

Urinary Tract Complications Depending on the location of the stone, symptoms may include urination urgency, frequent urination, or inability to urinate. Stones that are unable to pass through the ureter can cause a urinary tract obstruction and possibly lead to infection.

Prevention and Treatment of Kidney Stones

Solutes are less likely to crystallize and form stones in dilute urine. Therefore, people who form kidney stones are advised to drink 12 to 16 cups of fluids daily in order to maintain urine volumes of least $2^1/_2$ liters per day.[42] Additional fluid may be needed in hot weather or if an individual is extremely active. Acceptable fluid sources include tea, coffee, wine, and beer, but apple and grapefruit juices should be limited because they may increase the risk of stones.[43]

Calcium Oxalate Stones Dietary measures and drug treatments aim to reduce urinary calcium and oxalate levels. Furthermore, the uric acid content of urine must be kept low, because uric acid reduces the solubility of calcium oxalate.[44] Thiazide diuretics are a mainstay of drug therapy and help to reduce urinary calcium by enhancing calcium reabsorption in the kidney tubules.[45] Other medications include cholestyramine, which reduces oxalate absorption, and allopurinol, which reduces uric acid production in the body. Potassium citrate can inhibit the formation and growth of crystals but may cause stomach upset and diarrhea.

Medical nutrition therapy includes adjustments in calcium, oxalate, protein, and sodium intakes.[46] Patients should consume adequate calcium from food sources (800 to 1200 milligrams per day) because dietary calcium combines with oxalate in the intestines, reducing oxalate absorption and helping to control hyperoxaluria. ◆ Conversely, low-calcium diets promote oxalate absorption and higher urinary oxalate levels. Foods high in oxalate should be restricted, because dietary oxalate contributes to urinary oxalate content (review Table 28-7). High protein and sodium intakes increase urinary calcium excretion, so moderate protein consumption (about 0.8 to 1.0 gram per kilogram of body weight per day) and sodium restriction (no more than 3450 milligrams daily) are also advised. Vitamin C intake should be limited to the DRI (75 and 90 milligrams per day for women and men, respectively).

Uric Acid Stones Drug treatments for uric acid stones include allopurinol to reduce urinary uric acid and potassium citrate to reduce urine acidity. Diets restricted in purines may also help to control urinary uric acid levels (review Table 28-8). Because all meats, poultry, fish, and shellfish contain considerable amounts of purines, strict dietary control over a long period may be difficult to achieve. In addition, the benefits of purine restriction are unknown.

Cystine and Struvite Stones High fluid intakes may prevent the formation of cystine stones in some patients, whereas other individuals require drug therapy to reduce cystine production in the body. Medications frequently prescribed include penicillamine and tiopronin, which reduce cystine levels, and potassium citrate, which reduces urine acidity.

Preventing urinary tract infections is an important strategy for preventing struvite stones. Patients with these stones may require antibiotic therapy to prevent further stone formation.

© James Darell/Getty Images

Drinking plenty of water throughout the day is the most important measure for preventing kidney stones.

◆ Because calcium supplements can elevate urinary calcium levels, they are not as helpful as food sources of calcium.

IN SUMMARY

Kidney stones form when stone constituents—calcium oxalate, calcium phosphate, uric acid, cystine, or magnesium ammonium phosphate—crystallize in urine. Complications include renal colic, difficulty with urination, and obstruction. Kidney stones may be prevented by maintaining urine volumes of at least $2^1/_2$ liters daily. Other dietary measures include consumption of enough calcium to control oxalate absorption, dietary oxalate and purine restrictions, a moderate protein intake, and sodium restriction.

Clinical Portfolio

1. A person with chronic kidney disease may need multiple medications to control disease progression and treat symptoms and complications. For people with diabetes and hyperlipidemias who develop chronic kidney disease, medications might include insulin, oral hypoglycemic drugs, antihypertensives, diuretics, lipid-lowering medications, and phosphate binders. Review the nutrition-related side effects of these medications. Describe the ways in which these medications may make it harder for people to maintain nutrition status.
2. Because the diet for chronic kidney disease is so restrictive, patients find it difficult to manage and maintain over the long term. Review the suggestions in the "How to" on p. 886. Can you think of additional suggestions that may help? List ideas that may help patients adjust to each of the different aspects of their renal diets.

NUTRITION ASSESSMENT CHECKLIST for People with Renal Disorders

Medical History

Check the medical record to determine:

- Degree of renal function
- Cause of the nephrotic syndrome or kidney failure
- Type of dialysis, if appropriate
- Whether the patient has received a kidney transplant
- Type of kidney stone

Review the medical record for complications that may alter nutritional needs:

- Anemia
- Diabetes mellitus
- Edema or oliguria
- Hyperlipidemia
- Hypertension
- Metabolic stress or infection
- Protein-energy malnutrition

Medications

Assess risks for medication-related malnutrition related to:

- Long-term use of medications
- Multiple medication use, especially if medications affect nutrition status

For all patients with renal diseases, note:

- Whether medications or supplements contain electrolytes that must be controlled
- Use of drugs or herbs that may be toxic to the kidneys

Dietary Intake

For patients with the nephrotic syndrome, kidney failure, or kidney transplants, assess intakes of:

- Protein and energy
- Fluid
- Vitamins, especially vitamin D
- Minerals, especially calcium, phosphorus, iron, and electrolytes

For patients with kidney stones or a history of kidney stones:

- Stress the need to drink plenty of fluids throughout the day.
- Assess intake of calcium, oxalate, sodium, protein, purines, or vitamin C, as appropriate for the type of stone.

Anthropometric Data

Take accurate baseline height and weight measurements. Keep in mind that:

- Fluid retention due to the nephrotic syndrome or kidney failure can mask malnutrition.
- For dialysis patients, the weight measured immediately after the dialysis treatment (called the *dry weight*) most accurately reflects the person's true weight. Rapid weight gain between dialysis treatments reflects fluid retention. If fluid retention is excessive, review fluid intake to determine if the patient understands and is complying with diet recommendations.

Laboratory Tests

Note that serum protein levels are often low in patients with nephrotic syndrome or kidney failure. Review the following laboratory test results to assess the degree of renal function and response to treatments:

- Blood urea nitrogen (BUN)
- Creatinine
- Glomerular filtration rate (GFR)
- Serum electrolytes
- Urinary protein

Check laboratory test results for complications associated with kidney disease, including:

- Anemia
- Hyperglycemia
- Hyperlipidemia
- Hyperparathyroidism (related to bone disease)

Physical Signs

For patients with nephrotic syndrome or kidney failure, look for physical signs of:

- Bone disease
- Dehydration or fluid retention
- Hyperkalemia
- Iron deficiency
- Uremia

STUDY QUESTIONS

CENGAGENOW™
To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Describe the kidneys' role in maintaining homeostasis. Discuss other functions of the kidneys. (pp. 873–874)
2. Define the nephrotic syndrome, and describe the consequences that can develop. Discuss the elements of dietary treatment recommended for the nephrotic syndrome. (pp. 874–876)
3. Describe acute renal failure, and list possible causes. Discuss how its consequences can disrupt health. Describe the medical treatment of patients with acute renal failure and the elements of nutrition therapy. (pp. 878–880)
4. Explain how chronic kidney disease differs from acute renal failure. What changes occur as chronic kidney disease progresses? Discuss the symptoms and complications associated with the uremic syndrome. (pp. 880–882)
5. Identify the objectives of treatment for chronic kidney disease, and discuss the role of dialysis. Describe how dietary recommendations change during the course of illness. (pp. 882–883)
6. What are the fluid and electrolyte (sodium, potassium, and phosphorus) recommendations for patients with chronic kidney disease? What adjustments are needed in vitamin and mineral intakes, and why? (pp. 884–885)
7. Explain why renal patients often have difficulty adhering to a renal diet. Discuss ways to help patients comply with recommendations. (p. 886)
8. Discuss the nutrient needs of a kidney transplant patient. How can immunosuppressive drug therapy affect nutrition status? (pp. 886–888)
9. Identify factors that affect kidney stone formation. Describe the composition of the most common types of kidney stones. Discuss dietary adjustments that may help to prevent kidney stone recurrence. (pp. 888–891)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 895.

1. Which of the following is *not* a function of the kidneys?
   a. activation of vitamin K
   b. maintenance of acid-base balance
   c. elimination of metabolic waste products
   d. maintenance of fluid and electrolyte balances
2. The nephrotic syndrome frequently results in:
   a. the uremic syndrome.
   b. oliguria.
   c. edema.
   d. renal colic.
3. Dietary recommendations for patients with the nephrotic syndrome include:
   a. a high-protein intake.
   b. sodium restriction.
   c. potassium and phosphorus restrictions.
   d. fluid restriction.
4. Hyperkalemia is often treated by:
   a. eliminating potassium from the diet.
   b. using diuretics to increase potassium losses.
   c. increasing fluid consumption.
   d. using potassium-exchange resins, which bind potassium in the GI tract.
5. Fluid requirements for oliguric patients are estimated by adding about ____ milliliters to the volume of urine output.
   a. 100
   b. 300
   c. 500
   d. 750
6. The most common cause of chronic kidney disease is:
   a. diabetes mellitus.
   b. hypertension.
   c. autoimmune disease.
   d. exposure to toxins.
7. A person with chronic kidney disease, who has been following a renal diet for several years, begins hemodialysis treatment. An appropriate dietary adjustment would be to:
   a. reduce protein intake.
   b. consume protein more liberally.
   c. increase intakes of sodium and water.
   d. consume potassium and phosphorus more liberally.
8. Which of the following nutrients may be unintentionally restricted when a patient restricts phosphorus intake?
   a. fluid
   b. calcium
   c. potassium
   d. sodium
9. Most kidney stones are made primarily from:
   a. struvite.
   b. uric acid.
   c. calcium oxalate.
   d. cystine.
10. Treatment for all kidney stones includes:
    a. dietary oxalate restriction.
    b. dietary protein restriction.
    c. vitamin C supplementation.
    d. a fluid intake that maintains a urine volume of at least $2^1/_2$ liters per day.

Dialysis

Although there is no perfect substitute for one's own kidneys, dialysis offers a life-sustaining treatment option for people with chronic kidney disease who develop renal failure. Dialysis can serve as a permanent treatment or as a temporary measure to sustain life until a suitable kidney donor can be found. Dialysis can also restore fluid and electrolyte balances in patients with acute renal failure. Clinicians who routinely work with renal patients should understand how dialysis procedures work. This highlight describes the process of dialysis and outlines the different types of procedures used. The accompanying glossary defines the relevant terms.

The Basics of Dialysis

As described in this section, dialysis removes excess fluids and wastes from the blood by employing the processes of **diffusion, osmosis,** and **ultrafiltration** (see Figure H28-1). The dialysate, a solution similar in composition to normal blood plasma, is delivered to a compartment beside a **semipermeable membrane;** the person's blood flows along the other side of the membrane. The semipermeable membrane acts like a filter: small molecules such as urea and glucose can pass through microscopic pores in the membrane, whereas large molecules are unable to cross.

In *hemodialysis,* the tiny tubes that carry blood through the dialyzer are made of materials that serve as semipermeable membranes. In *peritoneal dialysis,* the body's peritoneal membrane, rich with blood vessels, is used to filter blood.

Removal of Solutes

The chemical composition of the dialysate affects the movement of solutes across the semipermeable membrane. When the concentration of a substance is lower in the dialysate than in the blood, the substance—provided it can cross the membrane—will diffuse out of the blood. For example, the goal is to remove as much as possible of the waste product urea from the blood, so the dialysate contains no urea. For many other solutes, the dialysate is adjusted so that only excesses will be removed. Potassium can be removed from the blood, for example, by providing a dialysate that has a lower concentration of potassium than is found in the person's blood. The dialysate must contain some potassium, however; otherwise the blood potassium would fall too low.

The dialysate can also be used to add needed components back into the blood. For a person with acidosis, for example, bases such as bicarbonate are added to the dialysate; the bases then move by diffusion into the blood to alleviate the acidosis.

Removal of Fluid

Because albumin and other plasma proteins are so adept at retaining fluids in blood, osmosis alone is not an efficient process for removing fluid. In hemodialysis, a **pressure gradient** is created between the blood and the dialysate. Most modern dialyzers produce *positive* pressure in the blood compartment and *negative* pressure in the dialysate compartment, establishing a pressure

GLOSSARY

continuous ambulatory peritoneal dialysis (CAPD): the most common method of peritoneal dialysis; involves frequent exchanges of dialysate, which remains in the peritoneal cavity throughout the day.

continuous renal replacement therapy (CRRT): a slow, continuous method of removing solutes and/or fluids from blood by gently pumping blood across a filtration membrane over a prolonged time period.

diffusion: movement of solutes from an area of high concentration to one of low concentration.

hemofiltration: removal of fluid and solutes by pumping blood across a membrane; no osmotic gradients are created during the process.

oncotic pressure: the pressure exerted by fluid on one side of a membrane as a result of osmosis.

osmosis: movement of water across a membrane toward the side where solutes are more concentrated.

peritonitis: inflammation of the peritoneal membrane.

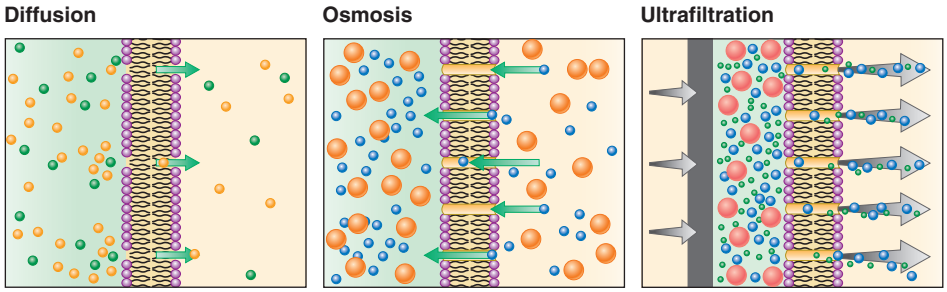
pressure gradient: the change in pressure over a given distance. In dialysis, a pressure gradient is created between the blood and the dialysate.

semipermeable membrane: a membrane that allows some particles to pass through, but not others.

ultrafiltration: removal of fluids and solutes from blood by using pressure to transfer the blood across a semipermeable membrane.

urea kinetic modeling: a method of determining the adequacy of dialysis treatment by calculating the urea clearance from blood.

FIGURE H28-1 Diffusion, Osmosis, and Ultrafiltration



Small molecules (electrolytes and waste products) move from an area of high concentration to an area of low concentration by diffusion.

Water moves from an area of high water concentration to an area of low water concentration. In other words, water moves toward the side where solutes are more concentrated.

Pressure squeezes water and small molecules through the pores of a semipermeable membrane during ultrafiltration.

gradient that "pushes" water (and accompanying solutes) through the pores of the membrane.[1] This process, called ultrafiltration, relies on pumps to establish an appropriate flow rate between the blood and the dialysate.

Evaluation of Dialysis Treatment

A number of methods have been devised for gauging the adequacy of dialysis treatment. The most common method is **urea kinetic modeling,** a technique that evaluates the amount of urea cleared from the blood. The formula used most often is *Kt/V,* where *K* is the amount of urea cleared, *t* is the time spent on dialysis, and *V* is the blood volume. The value obtained indicates whether the patient has undergone sufficient dialysis; the goal is a *Kt/V* result of approximately 1.2. Because technical data (such as dialyzer clearance data, blood flow rate, and dialysate flow rate) need to be incorporated into the calculation, the computation is usually done by computer analysis. Current treatment guidelines recommend that hemodialysis adequacy be evaluated at least monthly, or more often if problems develop or patients are noncompliant.[2]

Hpa-Voisin/Photo Researchers

During hemodialysis, blood passes through a dialyzer, where wastes are extracted, and the cleansed blood is returned to the body.

Types of Dialysis

Three approaches are currently used to remove fluids and wastes from the body: hemodialysis, peritoneal dialysis, and continuous renal replacement therapy. The latter procedure is used only to treat acute renal failure.

Hemodialysis

As described previously, hemodialysis utilizes a dialyzer to cleanse the patient's blood. Although dialyzers vary in efficiency, the treatment usually lasts 3 to 4 hours and is required at least 3 times weekly. Some studies suggest that patients undergoing daily hemodialysis for briefer periods (2 to $2^1/_2$ hours) may tolerate dialysis treatment better and have fewer complications, but this approach has not been widely adopted.[3] Most patients visit dialysis centers to obtain treatment; home hemodialysis programs are available, but only about 2 percent of patients use them.

Although lifesaving, hemodialysis is associated with a substantial number of complications.[4] Problems at the vascular access site include infections and blood clotting. Hypotension can develop while blood is circulated through the dialyzer. Muscle cramping often occurs during the procedure, especially in the hands, legs, and feet. Blood losses can worsen anemia, which is already severe in two-thirds of patients beginning hemodialysis treatment.[5] Patients may also experience headaches, weakness, nausea, vomiting, restlessness, and agitation.[6]

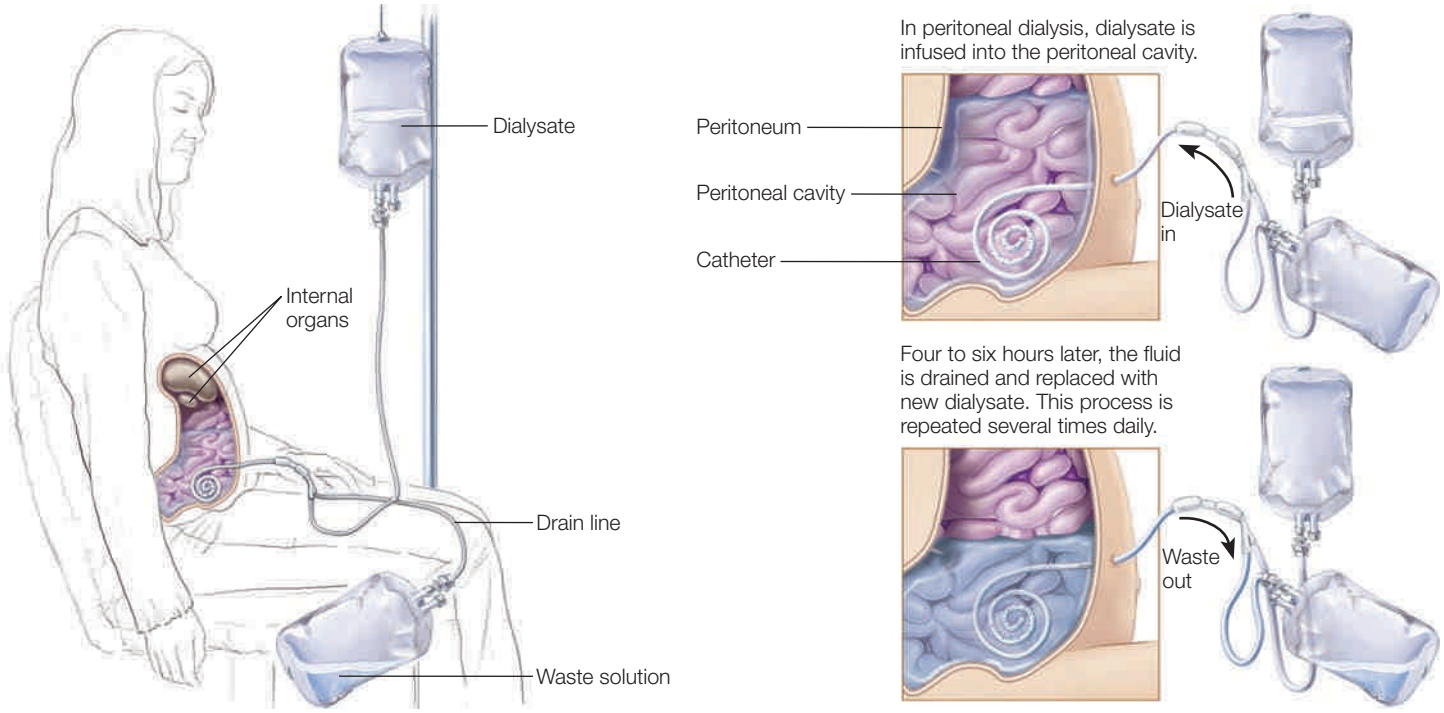
Peritoneal Dialysis

In peritoneal dialysis, the peritoneal membrane surrounding the abdominal organs serves as a semipermeable membrane. The dialysate is infused into a catheter that empties into the peritoneal space—the space within the abdomen near the intestines (see Figure H28-2 on p. 898). In the most common procedure, **continuous ambulatory peritoneal dialysis (CAPD),** the dialysate remains in the peritoneal cavity for 4 to 6 hours, after which it is drained and replaced with fresh dialysate (about 2 to 3 liters in adults). Generally, the dialysate solution is exchanged four times daily and requires only about 30 minutes to drain and replace.

Because a pressure gradient cannot be created in the peritoneal cavity, as it can in a dialyzer, the glucose concentration in the dialysate must be high enough to create enough **oncotic pressure** to draw fluid from the blood. As indicated in Chapter 28, a substantial amount of glucose can be absorbed into the patient's blood and may contribute to weight gain over time. The high glucose load may also cause hyperglycemia and hypertriglyceridemia in some patients.

Peritoneal dialysis offers a number of advantages over hemodialysis: vascular access is not required, dietary restrictions are fewer, and the procedure can be scheduled when convenient.

FIGURE H28-2 Peritoneal Dialysis



The most common complication is infection, which can occur at the catheter site or within the peritoneal cavity **(peritonitis).** Other problems that may arise include blood clotting in the catheter, catheter migration, and abdominal hernia due to the dialysate volume.

Continuous Renal Replacement Therapy

In people with acute renal failure, **continuous renal replacement therapy (CRRT)** removes fluids and wastes. CRRT utilizes the process of **hemofiltration,** in which blood is gently pumped across a filtration membrane over a prolonged time period. (This process differs from dialysis treatments that rely on the diffusion of wastes across a membrane into the dialysate.) Either a pump or the patient's own blood pressure moves the blood across the membrane. The procedure can be used to remove fluids, solutes, or both. Some patients require fluid replacement during the procedure to maintain adequate blood volume, so hydration status must be closely monitored.

The use of CRRT is advantageous in acute care situations because it corrects imbalances without causing sudden shifts in blood volume, which are poorly tolerated in acute care patients. In addition, replacement fluids can include parenteral feedings without upsetting fluid balance. Complications include clotting problems, damage to arteries, and inadequate blood flow rates in hypotensive patients.

Dialysis and CRRT help to remove the wastes and fluids that are normally removed by healthy kidneys. Although these procedures cannot restore the kidneys' hormonal functions, they provide a lifesaving means of alleviating symptoms of uremia, hypertension, and edema.

Nutrition in the Clinical Setting

A diagnosis of cancer or HIV infection can be devastating. Patients will likely expect an ever-worsening course of illness and, possibly, death. Medical management soon becomes an ever-present burden, and treatments are often unpleasant. For both illnesses, however, extraordinary therapeutic advances have been made. Treatment options have expanded, and patients have benefited from vast improvements in quality of life. The health practitioner's knowledge and empathy are the patient's most important resources—and an important source of hope.

CHAPTER 29

Cancer and HIV Infection

CHAPTER OUTLINE

Cancer • How Cancer Develops • Nutrition and Cancer Risk • Consequences of Cancer • Treatments for Cancer • Medical Nutrition Therapy for Cancer

HIV Infection • Consequences of HIV Infection • Treatments for HIV Infection • Medical Nutrition Therapy for HIV Infection

HIGHLIGHT 29 Complementary and Alternative Medicine

Although **cancers** and **HIV (human immunodeficiency virus)** infections are distinct disorders, from a nutritional standpoint they share some similarities. Both disorders have debilitating effects that influence nutritional needs, and both can lead to severe wasting in advanced cases. These illnesses require medical nutrition therapy that is highly individualized based on the symptoms manifested and the organ systems involved.

Cancer

Cancer, the growth of **malignant** tissue, ranks just below cardiovascular disease as a cause of death in the United States. Cancer is not a single disorder, however; there are many different kinds of malignant growths. The different types of cancer have different characteristics, occur in different locations in the body, take different courses, and require different treatments. ◆ Whereas an isolated, nonspreading type of skin cancer may be removed in a physician's office with no effect on nutrition status, advanced cancers—especially those of the gastrointestinal (GI) tract and pancreas—can seriously impair nutrition status.

How Cancer Develops

The development of cancer, called **carcinogenesis,** often proceeds slowly and continues for several decades. A cancer arises from mutations in the genes that control cell division in a single cell.[1] These mutations may promote cellular growth, interfere with growth restraint, or prevent cellular death. The affected cell thereby loses its built-in capacity for halting cell division and produces daughter cells with the same genetic defects. As the abnormal mass of cells, called a **tumor** (or *neoplasm*), grows, ◆ blood vessels form to supply the tumor with the nutrients it needs to support its growth. The tumor can disrupt the functioning of the normal tissue around it, and some tumor cells may **metastasize,** spreading to another region in the body. In leukemia (cancer affecting the white blood cells), the abnormal cells do not form a tumor but rather accumulate in the blood and other tissues. Figure 29-1 on p. 902 illustrates the steps in cancer development.

cancers: malignant growths or tumors that result from abnormal and uncontrolled cell division.

HIV (human immunodeficiency virus): the virus that causes acquired immune deficiency syndrome (AIDS). HIV destroys immune cells and progressively impedes the body's ability to fight infections and certain cancers.

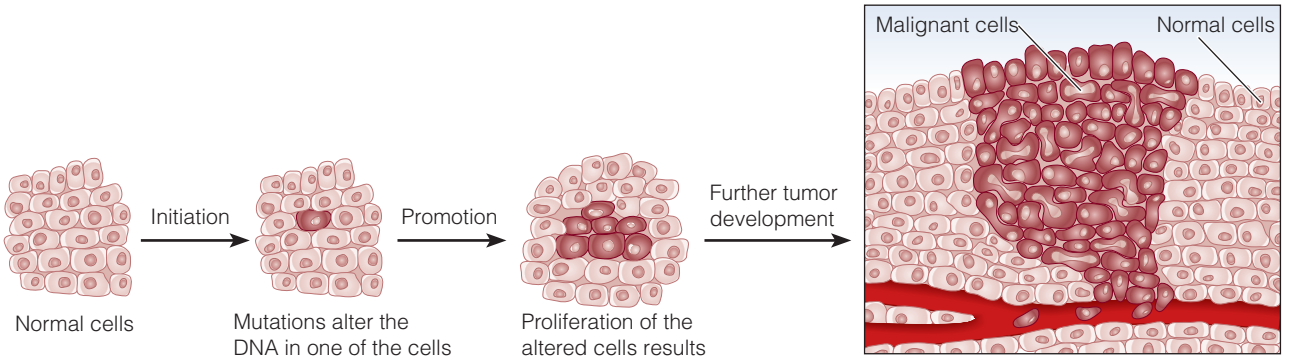
malignant (ma-LIG-nent): describes a cancerous cell or tumor, which can injure healthy tissue and spread cancer to other regions of the body.

carcinogenesis (CAR-sin-oh-JEN-eh-sis): the process of cancer development.

tumor: an abnormal tissue mass that has no physiological function; also called a *neoplasm* (NEE-oh-plazm).

metastasize (meh-TAS-tah-size): the spread of cancer cells from one part of the body to another.

FIGURE 29-1 Cancer Development



- Cancers are classified by the tissues or cells from which they develop:
  - *Adenomas* (ADD-eh-NO-muz) arise from glandular tissues.
  - *Carcinomas* (CAR-sih-NO-muz) arise from epithelial tissues.
  - *Gliomas* (gly-OH-muz) arise from glial cells of the central nervous system.
  - *Leukemias* (loo-KEY-mee-uz) arise from white blood cell precursors.
  - *Lymphomas* (lim-FOE-muz) arise from lymphoid tissues.
  - *Melanomas* (MEL-ah-NO-muz) arise from pigmented skin cells.
  - *Myelomas* (MY-ah-LOE-muz) arise from plasma cells in the bone marrow.
  - *Sarcomas* (sar-KO-muz) arise from connective tissues, such as muscle or bone.
- An abnormal mass of cells that is noncancerous is called a *benign* tumor.

The reasons why cancers develop are numerous and varied. Vulnerability to cancer is sometimes inherited, as when a person is born with a genetic defect that alters DNA structure, function, or repair. Certain metabolic processes may initiate carcinogenesis, as when phagocytes (immune cells) produce oxidants that cause DNA damage, or when chronic inflammation increases the rate of cell division, increasing the risk of a damaging mutation. More often, cancers are caused by interactions between a person's genes and environmental agents. Exposure to cancer-causing substances, or **carcinogens,** may either induce genetic mutations that lead to cancer or promote proliferation of cancerous cells. Table 29-1 provides examples of environmental factors that increase cancer risk.

carcinogens (CAR-sin-oh-jenz or car-SIN-oh-jenz): substances that can cause cancer (the adjective is *carcinogenic*).

TABLE 29-1 Environmental Factors That Increase Cancer Risk

Environmental Factors	Cancer Sites
Aflatoxins (toxins in moldy peanuts or grains)	Liver
Alcohol[a]	Mouth, pharynx, larynx, esophagus, colon, rectum, liver, breast
Asbestos[b]	Lung, pleura, peritoneum
Chromium (hexavalent) compounds	Nasal cavity, lung
Estrogen-progesterone replacement therapy	Breast
Immunosuppressive medications	Lymphoid tissues, liver
Infection with *Helicobacter pylori*	Stomach
Infection with hepatitis B and hepatitis C viruses	Liver
Infection with human papillomavirus (HPV)	Cervix
Ionizing radiation (X-rays, radioactive isotopes, and other sources)	White blood cells (leukemia), esophagus, stomach, colon, thyroid, lung, bladder, breast
Tobacco[a]	Nasal cavity, lung, mouth, pharynx, larynx, esophagus, stomach, colon, rectum, liver, pancreas, kidney, renal pelvis, bladder
Ultraviolet radiation (sun exposure)	Skin

[a]A combined exposure to alcohol and tobacco multiplies the risks of developing cancers of the oral cavity, pharynx, larynx, and esophagus.
[b]Risk is greatly increased in cigarette smokers.
SOURCES: M. J. Thun, Epidemiology of cancer, in L. Goldman and D. Ausiello, eds., *Cecil Medicine* (Philadelphia: Saunders, 2008), pp. 1335–1340; World Cancer Research Fund/American Institute for Cancer Research, *Food, Nutrition, Physical Activity, and the Prevention of Cancer: A Global Perspective* (Washington, D.C.: American Institute for Cancer Research, 2007), pp. 157–171.

Nutrition and Cancer Risk

Like other environmental factors, diet and lifestyle strongly influence cancer risk. Certain food components may directly damage DNA, alter the metabolism of carcinogens by liver enzymes, or inhibit the formation of carcinogens in the body.[2] In addition, energy balance and growth rates affect the rate of cell division and consequently influence the rates at which mutations form and are replicated. Table 29-2 lists examples of nutrition-related factors that may increase or decrease the risk of developing cancer.

Nutrition and Increased Cancer Risk As shown in Table 29-2, obesity is a risk factor for a number of different cancers, including some relatively common cancers such as colon cancer and postmenopausal breast cancer. Obesity increases cancer risk, in part, by altering levels of hormones that influence cell growth, such as the sex hormones, insulin, and several kinds of growth factors. For example, in the case of breast cancer in postmenopausal women, the hormone estrogen is likely involved: obese women have higher estrogen levels than do lean women, because adipose tissue produces estrogen.

Although studies in animals have suggested that high-fat diets can promote tumor growth, studies of humans have not proved that the effects of fat are independent of the effects of energy intake and physical activity.[3] Evidence from population studies is mixed: high-fat diets often, but not always, correlate with high cancer rates. Within single populations, cancer rates do not reliably reflect fat intakes. In addition, the type of fat consumed may be critical: studies of colon and rectal cancers implicate animal fats but not vegetable fat, and a number of studies suggest that consuming fatty fish may be protective.[4]

TABLE 29-2 Nutrition-Related Factors That Influence Cancer Risk

Nutrition-Related Factors[a]	Cancer Sites
Factors that increase cancer risk:	
Obesity	Esophagus, colon, rectum, pancreas, gallbladder, kidney, breast (postmenopausal), endometrium
Red meat, processed meats	Colon, rectum
Salted and salt-preserved foods	Stomach
Beta-carotene supplements	Lung[b]
High-calcium diets (over 1500 mg daily)	Prostate
Low level of physical activity[c]	Colon, breast (postmenopausal), endometrium
Factors that decrease cancer risk:	
Fruits and nonstarchy vegetables	Lung, mouth, pharynx, larynx, esophagus, stomach
Carotenoid-containing foods	Lung, mouth, pharynx, larynx, esophagus
Tomato products	Prostate
Allium vegetables (onion, garlic)	Stomach, colon, rectum
Vitamin C–containing foods	Esophagus
Folate-containing foods	Pancreas
Fiber-containing foods	Colon, rectum
Milk and calcium supplements	Colon, rectum
High level of physical activity[c]	Colon, breast (postmenopausal), endometrium

[a]Altered cancer risk is associated with high intakes of the dietary substances listed. The cancer sites associated with alcohol are included in Table 29-1.
[b]Cancer risk is increased in tobacco smokers and may not apply to other groups.
[c]Physical activity may influence cancer risk by altering body fatness, intestinal transit time, insulin sensitivity, hormone levels, enzyme activities, and immune responses.

Cruciferous vegetables, such as cauliflower, broccoli, and brussels sprouts, contain nutrients and phytochemicals that inhibit cancer development.

Food preparation methods are responsible for producing certain types of carcinogens. Cooking meat, poultry, and fish at high temperatures causes carcinogens to form in these foods.[5] Carcinogens also accompany the smoke that adheres to food during grilling, and they are present in the charred surfaces of grilled meat and fish. However, the cancer risk from eating such foods is unclear, because the biological actions of these carcinogens are modulated by other dietary components, including compounds in vegetables and other plant foods. In several population studies, consumption of well-cooked meats was linked to cancers of the stomach, colon, breast, and prostate.[6]

Nutrition and Decreased Cancer Risk A considerable number of human studies have found a link between the consumption of fruits and vegetables and reduced incidences of certain cancers (review Table 29-2). Fruits and vegetables contain both nutrients and phytochemicals with antioxidant activity, and these substances may prevent or reduce the oxidative reactions in cells that cause DNA damage. Phytochemicals may also help to inhibit carcinogen production in the body, enhance immune functions that protect against cancer development, and promote enzyme reactions that inactivate carcinogens.[7] In addition, certain fruits and vegetables provide the B vitamin folate, which plays roles in DNA synthesis and repair; thus, inadequate folate intakes may allow DNA damage to accumulate.

Although research reports in the 1970s and 1980s suggested that a fiber-rich diet could protect against colon cancer, recent studies have cast doubt on the earlier analyses.[8] The earlier studies depended on the ability of colon cancer patients to recall the foods they had consumed during the preceding years, whereas more recent studies—considered more reliable—tracked the subjects' health behaviors and cancer outcomes for extended periods (10 to 20 years). Moreover, some studies that had found fiber to be protective did not analyze factors such as physical activity, smoking, or folate intake, all of which can influence cancer outcome. A fiber-rich diet may be protective, in part, because high-fiber foods usually contain high levels of nutrients and phytochemicals that are protective against cancer. Table 29-3 summarizes the dietary and lifestyle practices that may help to reduce the risk of developing cancer.

TABLE 29-3 Recommendations for Reducing Cancer Risk

Maintain a healthy body weight.

- Balance energy intake with appropriate physical activity.
- Avoid weight gain and increases in waist circumference throughout adulthood.
- If overweight or obese, achieve a healthy body weight.

Be physically active.

- For adults: engage in moderate to vigorous activity for 30 minutes on at least 5 days of the week; 45 to 60 minutes is preferable.
- For children and adolescents: engage in moderate to vigorous activity for 60 minutes on at least 5 days of the week.

Choose a healthy diet that emphasizes plant sources.

- Consume five or more servings of a variety of vegetables and fruits daily.
- Choose whole-grain products instead of processed (refined) grains.
- Limit consumption of red meats and processed meats.
- Avoid salt-preserved and salty foods.
- Avoid moldy grains and legumes.

Limit consumption of alcoholic beverages.

- For women: drink no more than one drink daily.
- For men: drink no more than two drinks daily.

Avoid using tobacco in any form.

H. Kushi and coauthors, American Cancer Society guidelines on nutrition and physical activity for cancer prevention: Reducing the risk of cancer with healthy food choices and physical activity, *CA: A Cancer Journal for Clinicians* 56 (2006): 254–281.

Consequences of Cancer

Once cancer develops, its consequences depend on the location of the tumor, its severity, and the treatment. The complications that develop are often due to the tumor's impingement on surrounding tissues. Nonspecific effects of cancer include anorexia, lethargy, weight loss, night sweats, and fever.[9] During the early stages, many cancers produce no symptoms, and the person may be unaware of the threat to health.

Wasting Associated with Cancer Anorexia, muscle wasting, weight loss, and fatigue typify **cancer cachexia,** which eventually affects over 80 percent of people with terminal cancer.[10] Weight loss is often evident at the time that cancer is diagnosed, and severe malnutrition, typically seen in the later stages of cancer, is the ultimate cause of death in many cases. Without adequate energy and nutrients, the body is poorly equipped to maintain organ function, support immune defenses, and mend damaged tissues. An involuntary weight loss of more than 10 percent, which indicates significant malnutrition, is cause for concern.[11]

Many factors play a role in the wasting associated with cancer. Cytokines, ◆ released by both tumor cells and immune cells, induce a catabolic state. The combined effects of a poor appetite, accelerated and abnormal metabolism, and the diversion of nutrients to support tumor growth result in a lower supply of energy and nutrients at a time when demands are high. Appetite and food intake are further disturbed by the effects of treatments and medications prescribed for cancer patients.

◆ The cytokines that induce cachexia include tumor necrosis factor-α, interleukin-1, interleukin-6, and γ-interferon.

Metabolic Changes The metabolic changes that arise in cancer exacerbate the wasting described in the previous section.[12] Cancer patients exhibit an increased rate of protein turnover, but reduced muscle protein synthesis. ◆ Gluconeogenesis increases, further straining the body's supply of protein (recall that muscle supplies the amino acids used in glucose production). Triglyceride breakdown increases, elevating serum lipids. Many patients develop insulin resistance. These metabolic abnormalities help to explain why people with cancer fail to regain lean tissue or maintain healthy body weights even when they are consuming adequate energy and nutrients.

◆ Reminder: *Protein turnover* refers to the continuous degradation and synthesis of the body's proteins.

Anorexia and Reduced Food Intake Anorexia is a major contributor to the wasting associated with cancer. Some factors that contribute to anorexia or otherwise reduce food intake include:

- *Chronic nausea and early satiety.* People with cancer frequently experience nausea and a premature feeling of fullness after eating small amounts of food.
- *Fatigue.* People with cancer often tire easily and lack the energy to prepare and eat meals. Once cachexia develops, these tasks become even more difficult.
- *Pain.* People in pain may have little interest in eating, particularly if eating makes the pain worse.
- *Mental stress.* A cancer diagnosis can cause distress, anxiety, and depression, all of which may reduce appetite. Facing and undergoing cancer treatments induces additional psychological stress.
- *Effects of cancer therapies.* Therapies for cancer (including medications, chemotherapy, radiation therapy, surgery, and bone marrow transplants) can reduce food intake by causing nausea, vomiting, altered taste perceptions, food aversions, inflammation of the mouth and esophagus, dry mouth, mouth sores, difficulty swallowing, intestinal cramping, diarrhea, and constipation.
- *Gastrointestinal obstructions.* A tumor may partially or completely obstruct a portion of the GI tract, causing complications such as nausea and vomiting, early satiety, delayed gastric emptying, and bacterial overgrowth. Some patients with obstructions are unable to tolerate oral diets.

cancer cachexia (ka-KEK-see-ah): a wasting syndrome associated with cancer that is characterized by anorexia, muscle wasting, weight loss, and fatigue.

TABLE 29-4 Nutrition-Related Side Effects of Cancer Surgeries

Head and Neck Surgeries
- Difficulty with chewing/swallowing
- Inability to chew/swallow

Esophageal Resection
- Diarrhea
- Fistula formation
- Reduced gastric acid secretion
- Reduced gastric motility
- Steatorrhea (fat malabsorption)
- Stenosis (constriction)

Gastric Resection
- Dumping syndrome
- General malabsorption
- Hypoglycemia
- Lack of gastric acid
- Vitamin B_{12} malabsorption

Intestinal Resection
- Blind loop syndrome
- Diarrhea
- Fluid and electrolyte imbalances
- Hyperoxaluria
- Malabsorption
- Steatorrhea

Pancreatic Resection
- Diabetes mellitus
- Malabsorption

◆ One drug that inhibits cell division is *methotrexate,* which closely resembles the B vitamin folate (see Figure 19-1 on p. 651). Folate is required for cell division because it is needed for DNA synthesis. Methotrexate works by blocking activity of the enzyme that converts folate to its active form.

chemotherapy: the use of drugs to arrest or destroy cancer cells; these drugs are called *antineoplastic agents.*

radiation therapy: the use of X-rays, gamma rays, or atomic particles to destroy cancer cells.

radiation enteritis: inflammation of intestinal tissue caused by radiation therapy.

bone marrow transplant: a procedure that replaces bone marrow that has been destroyed by cancer treatment; it is also used to treat certain types of cancers and blood disorders. Also called *hematopoietic stem cell transplantation.*

tissue rejection: destruction of donor tissue by the recipient's immune system, which recognizes the donor cells as foreign.

Treatments for Cancer

The primary medical treatments for cancer—surgery, chemotherapy, radiation therapy, or any combination of the three—aim to remove cancer cells, prevent further tumor growth, and alleviate symptoms.[13] The likelihood of effective treatment is highest with early detection and intervention. Because treatment decisions are difficult and cancer therapies have considerable side effects, patients rely on health care providers to help them make informed decisions.

Surgery Surgery is performed to remove tumors, determine the extent of cancer, and protect nearby tissues. Often, surgery must be followed by other cancer treatments to prevent growth of new tumors. The acute metabolic stress caused by surgery raises protein and energy needs and can exacerbate wasting. Surgery also contributes to pain, fatigue, and anorexia, all of which can reduce food intake at a time when nutritional needs are substantial. Blood loss contributes to nutrient losses and further exacerbates malnutrition. Some surgeries can have long-term effects on nutrition status (see Table 29-4).

Chemotherapy **Chemotherapy** relies on the use of drugs to treat cancer; it is used to inhibit tumor growth, shrink tumors before surgery, and prevent or eradicate metastasis. Some cancer drugs interfere with the process of cell division; ◆ others sterilize cells that are in a resting phase and are not actively dividing. Ideally, chemotherapy would wipe out cancer cells without destroying healthy ones. Unfortunately, most of these drugs have toxic effects on normal cells as well and are especially damaging to rapidly dividing cells, such as those of the GI tract, skin, and bone marrow. Some of the newer drugs are able to target properties specific to cancer cells and are better tolerated by the body's tissues. Table 29-5 includes a summary of the nutrition-related side effects that may result from chemotherapy.

Radiation Therapy **Radiation therapy** treats cancer by bombarding cancer cells with X-rays, gamma rays, or various atomic particles. These treatments induce the formation of reactive oxygen species, ◆ such as superoxide and hydroxyl radicals, which can damage cellular DNA and cause cell death. Newer techniques are able to focus radiation directly at tumors and minimize damage to nearby tissues. An advantage of radiation therapy over surgery is that it can shrink tumors while preserving organ structure and function. Compared with chemotherapy, radiation therapy is better able to target specific regions of the body, rather than involving all body cells. Nonetheless, radiation therapy can damage healthy tissues and sometimes has long-term detrimental effects on nutrition status. Radiation to the head and neck area can damage the salivary glands and taste buds, causing inflammation, dry mouth, and a reduced sense of taste; in severe cases, damage may be permanent. Radiation treatment in the lower abdominal area can cause **radiation enteritis,** an inflammatory condition of the small intestine that causes nausea, vomiting, malabsorption, and diarrhea. Table 29-5 includes additional side effects of radiation treatment that affect nutrition status.

Bone Marrow Transplant A **bone marrow transplant** replaces bone marrow that has been destroyed by chemotherapy or radiation therapy, and it is one of the primary treatments for leukemia, lymphomas, and multiple myeloma.[14] If possible, bone marrow cells are collected from the patient before chemotherapy or radiation treatment begins so that it is not necessary to find a separate donor. If another person's cells are used, the patient must take immunosuppressant drugs to prevent **tissue rejection.**

The treatments that bone marrow transplant patients undergo have a substantial impact on their food intake and nutrition status. The chemotherapy or radiation therapy preceding the transplant and the immunosuppressant drugs required afterward can impair immune function substantially and increase the risk of foodborne illness. Other common complications include anorexia, dry mouth, altered taste sensations, inflamed mucous membranes, malabsorption, nausea, vomiting, and diarrhea. Patients are often unable to consume adequate food and may require nutrition support, as described in a later section.

TABLE 29-5 Nutrition-Related Side Effects of Chemotherapy and Radiation Therapy

	Reduced Nutrient Intake	Accelerated Nutrient Losses	Altered Metabolism
Chemotherapy	Abdominal pain Anorexia Mouth ulcers Nausea Taste alterations Vomiting	Diarrhea Intestinal ulcers Malabsorption Vomiting	Fluid and electrolyte imbalances Hyperglycemia Interference with vitamins or other metabolites Negative nitrogen and calcium balances Secondary effects of malnutrition, infection, or tissue damage (inflammation)
Radiation	Anorexia Damage to teeth and jaws Dysphagia Esophagitis Mouth ulcers Nausea Reduced salivary secretions Taste alterations Thick salivary secretions Vomiting	Blood loss from intestine and bladder Diarrhea Fistulas Intestinal obstructions Malabsorption Radiation enteritis Vomiting	Fluid and electrolyte imbalances as a consequence of vomiting, diarrhea, or malabsorption Secondary effects of malnutrition, infection, or tissue damage (inflammation)

Medications to Combat Anorexia and Wasting To help cancer patients combat anorexia, medications may be prescribed to stimulate the appetite and promote weight gain. One of the most effective medications, megestrol acetate (Megace), is a synthetic compound similar in structure to the hormone progesterone. Dronabinol (Marinol), which resembles the psychoactive ingredient in marijuana, stimulates the appetite at doses that have minimal mental effects. Under investigation are medications that may help to restore lean tissue, such as anabolic steroids, growth hormone, and insulin-like growth factor.[15]

Alternative Therapies Many patients turn to *complementary and alternative medicine (CAM)* ◆ to assist them in their fight against cancer. Patients may turn to CAM because they wish to gain more control over treatment or because they are concerned about the effectiveness of conventional approaches. Although few abandon conventional medicine, up to 80 percent of cancer patients combine one or more CAM approaches with standard treatment.[16] Many patients do not discuss their use of CAM with physicians.

Dietary supplements and herbal remedies are among the most frequently used CAM therapies. Although many supplements can be used without risk, some may have adverse effects or interfere with conventional treatments. Use of the herbal remedy St. John's wort, for example, can reduce the effectiveness of some anticancer drugs.[17] As another example, some studies suggest that antioxidant supplements interfere with chemotherapy and radiation treatments.[18] Clinical trials of several popular supplements are in progress to learn more about their potential effects and interactions with treatments.

◆ Reminder: Reactive oxygen species and their effects on cells were described in Highlight 11.

◆ *Complementary and alternative medicine (CAM)* refers to health care practices that have not been proved to be effective and consequently are not included as part of conventional treatment. Highlight 29 provides additional information about CAM.

Medical Nutrition Therapy for Cancer

The objectives of medical nutrition therapy for cancer patients are to minimize loss of weight and muscle tissue, correct nutrient deficiencies, and provide a diet that patients can tolerate and enjoy despite the complications of illness. Appropriate nutrition care helps patients preserve their strength and improves recovery after stressful cancer treatments. Moreover, malnourished cancer patients develop more complications and have shorter survival times than patients who maintain good nutrition status.[19]

HOW TO Increase kCalories and Protein in Meals

To increase the energy content of a meal, try these suggestions:

- *Butter or margarine.* Melt on pasta, potatoes, rice, and cooked vegetables. Add to hot cereals, casseroles, and soups. Spread liberally on bread, crackers, and rolls.
- *Mayonnaise.* Add to pasta, tuna, and potato salads. Use as a dressing for raw or cooked vegetables.
- *Cream cheese.* Spread on raw vegetables, toast, and crackers. Mix into chopped fruit. Use as a spread in sandwiches made with luncheon meats.
- *Half-and-half and cream.* Replace milk or water with half-and-half or cream in soups, sauces, hot chocolate, desserts, mashed potatoes, and cold and cooked cereals.
- *Nuts.* Add chopped nuts to pasta dishes, stir-fried vegetables, fruit salads, and green salads. Use nut meats in baked products.
- *Beverages.* Replace water and nonkcaloric beverages with sweetened drinks, fruit juices, and milk shakes.

These suggestions can help to add protein to a meal:

- *Powdered milk* (*use full-fat milk powder, if available*). Add to recipes that include milk. Dissolve extra milk powder into milk-containing beverages. Stir into hot cereals, potato dishes, casseroles, and sauces. Add to scrambled eggs, hamburger, and meat loaf.
- *Cheese.* Melt on burgers, meat loaf, cooked vegetables, scrambled eggs, casseroles, and potatoes. Add cottage cheese to casseroles, egg dishes, pasta recipes, and salad dressings. Grate hard cheeses and sprinkle on soups, salads, and cooked vegetable dishes.
- *Eggs.* Add raw eggs when preparing casseroles, meatballs, and hamburgers. Add chopped hard-cooked eggs to salads, vegetable dishes, sandwich fillings, and pasta and potato salads.
- *Meats.* Add meat pieces to soups, egg dishes, casseroles, bean dishes, and pasta sauces. Add minced meats to vegetable dishes. Add chunks of cooked chicken or turkey to salads.

Because there are many forms of cancer and a variety of potential treatments, nutritional needs among cancer patients vary considerably. Furthermore, a person's needs may change at different stages of illness. Patients should be screened for malnutrition when cancer is diagnosed and be reassessed during the treatment and recovery periods.

Protein and Energy For patients at risk of weight loss and wasting, protein and energy needs are considerable. Protein recommendations range from 1.0 to 1.2 grams per kilogram of body weight for nonstressed patients, 1.2 to 1.5 grams per kilogram for those undergoing treatment, and 1.5 to 2.5 grams per kilogram for patients with substantial protein losses or cachexia.[20] Energy needs may be 25 to 35 kcalories per kilogram of body weight, depending on the patient's current weight, activity level, degree of metabolic stress, and energy needs for weight regain and tissue repair. Health practitioners should regularly monitor patients' weight changes and adjust intake recommendations as necessary. Patients who cannot eat adequate food may be able to meet their needs by supplementing the diet with nutrient-dense formulas. The "How to" above provides suggestions that can help to increase the energy and protein content of meals. ◆

◆ Reminder: The high-kcalorie, high-protein diet, which is appropriate for some individuals with cancer, was described in Chapter 18 (see p. 624).

Although weight loss is a problem for many cancer patients, breast cancer patients often gain weight.[21] The weight gain occurs during the first two years after breast cancer diagnosis and is associated with an increase in total body fat. By discussing weight maintenance soon after diagnosis and encouraging physical activity, health practitioners can help patients avoid unnecessary weight gain.

Managing Symptoms and Complications A thorough nutrition assessment often uncovers specific problems or symptoms that interfere with food consumption. Table 29-6 lists dietary considerations related to cancers affecting different sites in the body. The "How to" on p. 910 outlines a variety of dietary strategies that may improve food intake and alleviate symptoms. Patients' responses to these strategies may vary considerably, and in some cases a number of adjustments may be necessary.

Enteral and Parenteral Nutrition Support Nutrition support is used in limited situations during cancer treatment. Generally, tube feedings and parenteral nutrition are provided to patients who have long-term or permanent gastrointestinal impairment or are experiencing complications that interfere with food intake.[22] For example, many patients undergoing radiation therapy for head and neck cancers require long-term tube feeding and may need to continue tube feedings at home. ◆ Par-

◆ Irradiation to the head and neck regions often causes dysphagia and mouth sores.

TABLE 29-6 Dietary Considerations for Specific Cancers

Cancer Sites	Common Complications[a]	Possible Dietary Measures
Brain and nervous system	Chewing and swallowing difficulties, difficulty feeding oneself	Mechanically altered diet, use of adaptive feeding devices (see Highlight 27)
Head and neck[b]	Swallowing difficulty, aspiration, inflamed mucosa, dry mouth, altered taste sensation	Tube feeding, mechanically altered diet
Esophagus	Swallowing difficulty, obstruction, acid reflux, inflamed mucosa	Tube feeding, mechanically altered diet
Stomach	Anorexia, delayed stomach emptying, early satiety, dumping syndrome, malabsorption	Tube feeding (for obstruction or unmanageable dumping syndrome); postgastrectomy diet; small, frequent meals; limited sugars and insoluble fibers (see Chapter 23)
Intestine	Fluid and electrolyte imbalances, altered bowel function, malabsorption, lactose intolerance, inflamed mucosa, bacterial overgrowth, short bowel syndrome (if resected), obstruction	Tube feeding or total parenteral nutrition for obstruction, enteritis, or short bowel syndrome; fat- and lactose-restricted diet (see Chapter 24)
Pancreas	Malabsorption, bile insufficiency, hyperglycemia	Fat-restricted diet; enzyme replacement (see Chapter 24); small, frequent meals; carbohydrate-controlled diet (Chapter 26)

[a] Actual complications depend on the specific methods used for treating the cancer.
[b] Includes cancers of the pharynx, larynx, salivary glands, and oral and nasal cavities.

enteral nutrition is reserved for patients who have inadequate GI function, such as individuals with chronic radiation enteritis. Whenever possible, enteral nutrition is strongly preferred over parenteral nutrition, to preserve GI function and avoid infection.

Nutrition Therapy for Bone Marrow Transplant Patients Patients who undergo bone marrow transplants may require total parenteral nutrition (TPN) before and after the transplant, as the GI tract is often severely damaged by the chemotherapy or radiation treatment required beforehand. When GI function returns, the patient can begin consuming small amounts of food along with TPN. As oral intake improves, TPN is gradually tapered. Some patients may require a high-kcalorie, high-protein diet to reverse malnutrition. Because recipients of bone marrow transplants are severely immunocompromised, they should be instructed to follow safe food-handling practices to minimize the risk of foodborne illness (see Highlight 18). In addition, they must avoid foods that are likely to contain unsafe levels of bacteria, such as raw fruits and vegetables; undercooked meat, poultry, and eggs; leftover luncheon meats and meat spreads; blue-veined cheeses; unpasteurized dairy products, juices, honey, and beer; and foods from salad bars or street vendors.[23]

IN SUMMARY

Cancer arises from mutations in the genes that control cell division. Some dietary substances promote carcinogenesis, while others may help to prevent cancer. Cancer's effects on nutrition status depend on the type of cancer a person has, its severity, and the methods used to treat the cancer. Cancer cachexia is a frequent complication of cancer and may be related to anorexia, altered metabolism, and responses to treatment. Medical treatments for cancer include surgery, chemotherapy, and radiation therapy, which remove cancer cells, prevent tumor growth, and alleviate symptoms. Medical nutrition therapy for cancer patients aims to minimize weight loss and wasting, correct deficiencies, and manage complications that impair food intake. The accompanying Case Study on p. 911 allows you to apply information about nutrition and cancer to a clinical situation.

HOW TO Help Patients Handle Food-Related Problems

In people with cancer or HIV infections, various complications can interfere with eating. Health practitioners can try to identify the specific problems that patients are having and offer appropriate solutions. Not every suggestion will work for each patient; encourage patients to experiment and find the strategies that work best.

I just don't have an appetite.

- Eat small meals and snacks at regular times each day.
- Eat the largest meal at the time of day when you feel the best.
- Include nutrient-dense foods in meals, and consume them before other foods.
- Indulge in favorite foods throughout the day. Serve foods attractively.
- Avoid drinking large amounts of liquids before or with meals.
- Eat in a pleasant and relaxed environment. Eat with family and friends when possible.
- Listen to your favorite music or enjoy a program on TV while you eat.
- Take a walk before you eat.

I am too tired to fix meals and eat.

- Let family members and friends prepare food for you.
- Obtain foods that are easy to prepare and easy to eat, such as sandwiches, frozen dinners, take-out meals from restaurants, instant breakfast drinks, liquid formulas, and energy bars.

Foods just don't taste right.

- Brush your teeth or use mouthwash before you eat.
- Consume foods chilled or at room temperature.
- Choose eggs, fish, poultry, and milk products instead of meats.
- Experiment with sauces, seasonings, herbs, and spices to improve food's flavor.
- Use plastic, rather than metal, eating utensils.
- Save your favorite foods for times when you are not feeling nauseated.

I am nauseated a lot of the time, and sometimes I need to vomit.

- Consume liquids throughout the day to replace fluids.
- If you become nauseated from chemotherapy treatments, avoid eating for at least two hours before treatments.
- Consume smaller meals, and eat slowly.
- Avoid foods and meals that have strong odors or are fatty, greasy, or gas forming.

I am having problems chewing and swallowing food.

- Experiment with food consistencies to find the ones you can manage best. Thin liquids, dry foods, and sticky foods (such as peanut butter) are often difficult to swallow.
- Add sauces and gravies to dry foods.
- Drink fluids with meals to ease chewing and swallowing.
- Try using a straw to drink liquids.
- Tilt your head forward and backward to see if you can swallow more easily when your head is positioned differently.

I have sores in my mouth, and they hurt when I eat.

- Use cold or frozen foods; they are often soothing.
- Try soft foods such as ice cream, milk shakes, bananas, applesauce, mashed potatoes, cottage cheese, and macaroni and cheese.
- Avoid foods that irritate mouth sores, such as citrus fruits and juices, tomatoes and tomato-based products, spicy foods, foods that are very salty, foods with seeds (such as poppy seeds and sesame seeds) that can scrape the sores, and coarse foods such as raw vegetables and toast.
- Ask your doctor about using a local anesthetic solution such as lidocaine before eating to reduce pain.
- Use a straw for drinking liquids in order to bypass the sores.

My mouth is really dry.

- Rinse your mouth with warm saltwater or mouthwash frequently. Avoid using mouthwash that contains alcohol.
- Drink small amounts of liquid frequently between meals.
- Ask your doctor or pharmacist about medications that can help dry mouth.
- Use sour candy or gum to stimulate the flow of saliva.
- Add broth, sauces, gravies, mayonnaise, butter, or margarine to dry foods.
- Make sure you brush your teeth and floss regularly to prevent cavities and oral infections.

I am having trouble with diarrhea.

- Drink plenty of fluids. Salty broths and soups, diluted fruit juices, and sports drinks are good choices. For severe diarrhea, try oral rehydration formulas that are commercially prepared.
- Avoid foods and beverages that increase gas, such as legumes, onions, vegetables of the cabbage family, foods that contain sorbitol or mannitol, and carbonated beverages.
- Try using lactase enzyme replacements when you use milk products in case you are experiencing lactose intolerance. Yogurt and aged cheeses may be easier to tolerate than milk and fresh cheeses.
- Avoid high-fat foods if you are fat intolerant.
- Avoid caffeine.
- Eat smaller meals, and eat more frequently.
- Check with your doctor about using digestive enzyme replacements if you have had diarrhea for a long time.

I am having trouble with constipation.

- Drink plenty of fluids. Try warm fluids, especially in the morning.
- Eat whole-grain breads and cereals, nuts, fresh fruits and vegetables, prunes, and prune juice. Avoid refined carbohydrate foods such as white bread, white rice, and pasta.
- Engage in physical activity regularly.

CASE STUDY Public Relations Consultant with Cancer

Janet Woodhouse is a 58-year-old public relations consultant who was recently diagnosed with colon cancer after a routine colonoscopy, a procedure in which the colon is examined using a flexible tube attached to an optical device. Mrs. Woodhouse is scheduled to have surgery to remove the segment of colon that contains the tumor and to determine if the cancer has spread to the surrounding lymph nodes and, possibly, other organs. The nurse completing the nutrition assessment finds that Mrs. Woodhouse is 5 feet 5 inches tall and weighs 178 pounds. The patient spends most of the day sitting and has little time to engage in recreational exercise. Her diet is high in fat and typically includes red meat at both lunch and dinner. She eats two or three servings of fruits and vegetables each day, although she does not like green leafy vegetables very much. She rarely drinks milk or consumes milk products.

1. Review Table 29-2 on p. 903, and describe the factors in Mrs. Woodhouse's diet and lifestyle that may have contributed to the development of colon cancer.
2. What symptoms and complications may arise after colon surgery and impair nutrition status? If the cancer team decides that Mrs. Woodhouse needs follow-up chemotherapy, how might the chemotherapy affect her nutrition status?
3. If Mrs. Woodhouse is unresponsive to treatment and her cancer progresses, she may develop cancer cachexia. Describe this syndrome, its causes, and its consequences.
4. Provide suggestions that may help Mrs. Woodhouse handle the following problems should they develop: poor appetite, fatigue, taste alterations, nausea and vomiting, chewing and swallowing difficulties, mouth sores, dry mouth, diarrhea, constipation, and weight loss.

HIV Infection

Possibly, the most infamous infectious disease today is **acquired immune deficiency syndrome (AIDS).** AIDS develops from infection with HIV (human immunodeficiency virus), which attacks the immune system and disables a person's defenses against other diseases, including infections and certain cancers. Then these diseases—which would cause few, if any, symptoms in people with healthy immune systems—destroy health and life.

The HIV/AIDS epidemic continues to sweep across countries, especially in sub-Saharan Africa. Table 29-7 shows its impact worldwide and in North America. For many years the destructive effects of HIV infection seemed unstoppable, but in the mid to late 1990s the death rate from AIDS began to decline in the United States, and the progression from HIV infection to AIDS slowed dramatically. AIDS still has no cure, but remarkable progress has been made in understanding and treating HIV infection.

Without a cure for AIDS, the best course is prevention. HIV is most often sexually transmitted and can be spread by direct contact with contaminated body fluids, such as blood, semen, vaginal secretions, and breast milk. Because many people remain symptom-free during the early stages of infection, they may not realize that they can pass the infection to others. To reduce the spread of HIV infection, individuals at risk (see Table 29-8) are encouraged to undergo testing. A blood test can usually detect HIV antibodies within several months after exposure and, often, after 1 or 2 weeks. An estimated 25 percent of persons in the United States who have HIV infection are unaware that they are infected.[24]

Consequences of HIV Infection

HIV infection destroys immune cells that have a protein called CD4 on their surfaces. The cells most affected are the **helper T cells,** ◆ also called *CD4+ T cells* because the presence of CD4 is a primary characteristic. HIV is able to enter the helper T cells and induce them to produce additional copies of the virus, thus perpetuating

TABLE 29-7 The HIV and AIDS Epidemic at a Glance, 2007

Stage of Epidemic	World	North America
Individuals living with HIV infection or AIDS	33,200,000	1,300,000
Individuals newly infected with HIV	2,500,000	46,000
AIDS deaths	2,100,000	21,000

SOURCE: Joint United Nations Programme on HIV/AIDS and World Health Organization, *AIDS epidemic update: December 2007,* available at http://data.unaids.org/pub/EPISlides/2007/2007_epiupdate_en.pdf; site visited February 3, 2008.

TABLE 29-8 Risk Factors for HIV Infection

- History of receiving blood transfusions or clotting factors between 1978 and 1985
- Infant born to a mother with HIV infection
- Intravenous drug use in which syringes are shared among users
- Sexual contact with multiple partners
- Sexual contact with intravenous drug users, prostitutes, or individuals with a history of HIV or other sexually transmitted diseases
- Unsafe sexual practices

◆ *T cells* are lymphocytes that develop in the thymus gland. The other lymphocytes are the *B cells* (which develop in bone marrow) and *natural killer cells.*

acquired immune deficiency syndrome (AIDS): the late stage of illness caused by infection with the human immunodeficiency virus (HIV); characterized by severe damage to immune function.

helper T cells: lymphocytes that have a specific protein called CD4 on their surfaces and therefore are also known as *CD4+ T cells;* the cells most affected in HIV infection.

© Mediscan/Visuals Unlimited

HIV-lipodystrophy is sometimes evident by the accumulation of fatty tissue at the base of the neck, referred to as *buffalo hump*.

and exacerbating the infection. Other cells that have the CD4 protein (and are infected by HIV) include tissue macrophages, blood monocytes, and certain cells of the central nervous system.[25] Early symptoms of HIV infection are nonspecific and may include fever, sore throat, malaise, swollen lymph nodes, skin rashes, muscle and joint pain, and diarrhea. After these symptoms subside, many people remain symptom-free for 5 to 10 years or even longer. If the HIV infection is not treated, however, the depletion of T cells eventually increases the person's susceptibility to **opportunistic infections—**that is, infections caused by microorganisms that normally do not cause disease in healthy individuals.

The term *AIDS* applies to the advanced stages of HIV infection, in which the inability to fight illness allows a number of serious diseases and complications to develop; such **AIDS-defining illnesses** include severe infections, certain cancers, and wasting of muscle tissue. Health practitioners evaluate disease progression by measuring the concentrations of helper T cells and circulating virus (called the *viral load*) and by monitoring clinical symptoms. Although current drug therapies can dramatically slow the progression of HIV infection, the drugs' side effects may make it difficult for patients to adhere to treatments, as discussed in several of the following sections.

Lipodystrophy

Some of the drug treatments that suppress HIV infection cause abnormalities in glucose and fat metabolism, which affect an estimated 25 to 50 percent of these patients. These complications, collectively known as the **HIV-lipodystrophy syndrome,** include body fat redistribution, abnormal blood lipid levels, and insulin resistance.[26] Patients tend to accumulate abdominal fat and lose fat from the face, arms, and legs; thus, they appear to be thin except for a "pot belly." Also observed are breast enlargement (in both men and women), fat accumulation at the base of the neck (called a **buffalo hump**), and benign growths composed of fat tissue (called **lipomas**). The changes in body composition are often disfiguring and may cause physical discomfort; moreover, patients often develop hypertriglyceridemia, elevated LDL (low-density lipoprotein) cholesterol levels, low HDL (high-density lipoprotein) cholesterol levels, glucose intolerance, and hyperinsulinemia. The reasons for the development of lipodystrophy are unknown.

Weight Loss and Wasting

Even with effective treatment of HIV infection, weight loss and wasting are ongoing problems for HIV-infected patients.[27] The Centers for Disease Control and Prevention defines *AIDS-related wasting syndrome* as a 10 percent weight loss within a 6-month period, accompanied by diarrhea or fever without a known cause for more than 30 days. The wasting has been linked with accelerated disease progression, reduced strength, and fatigue. In the later stages of AIDS, wasting is severe and increases the risk of death. Much as in cancer, the wasting associated with HIV infection has many causes: anorexia and inadequate food intake, altered metabolism, malabsorption, chronic diarrhea, and diet-drug interactions.

Anorexia and Reduced Food Intake

As mentioned, inadequate food intake is a key factor in the development of wasting. Poor food intake may result from various factors, including the following:

- *Emotional distress, pain, and fatigue.* The physical and social problems that accompany chronic illness may cause fear, anxiety, and depression, which contribute to anorexia. Pain and fatigue, which may be associated with some disease complications, can cause anorexia and difficulty with eating.
- *Oral infections.* The oral infections associated with HIV infection can cause discomfort and interfere with food consumption. Common infections include thrush and herpes simplex virus infection. **Thrush** can cause mouth pain, dysphagia (difficulty swallowing), and altered taste sensation; infection with **herpes simplex virus** may cause painful lesions around the lips and in the mouth.
- *Respiratory disorders.* Respiratory infections, including pneumonia and tuberculosis, are common in people with HIV infection. Symptoms often include chest pain, shortness of breath, and cough, which interfere with eating and contribute to anorexia.

opportunistic infections: infections from microorganisms that normally do not cause disease in healthy people, but are damaging to persons with compromised immune function.

AIDS-defining illnesses: diseases and complications associated with the later stages of an HIV infection, including wasting, recurrent bacterial pneumonia, opportunistic infections, and certain cancers.

HIV-lipodystrophy (LIP-oh-DIS-tro-fee) **syndrome:** a group of abnormalities in fat and glucose metabolism that may result from drug treatments for HIV infection; changes include body fat redistribution, abnormal blood lipid levels, and insulin resistance. The accumulation of abdominal fat is sometimes called *protease paunch.*

buffalo hump: the accumulation of fatty tissue at the base of the neck.

lipomas (lih-POE-muz): benign tumors composed of fatty tissue.

thrush: a fungal infection of the mouth and throat, most often caused by *Candida albicans.*

herpes simplex virus: a common virus that can cause blisterlike lesions on the lips and in the mouth.

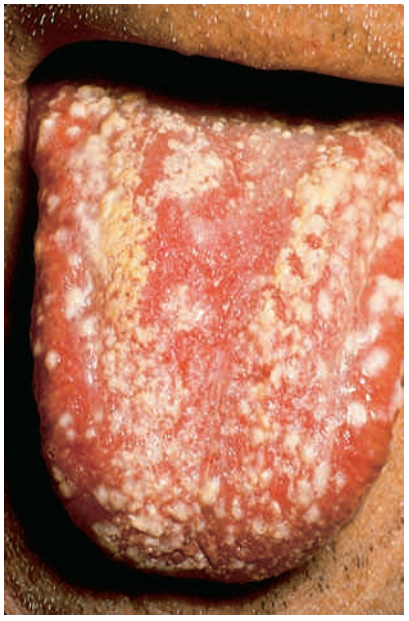
- *Cancer.* As described earlier in this chapter, cancer leads to anorexia for numerous reasons. In addition, **Kaposi's sarcoma,** a type of cancer frequently associated with HIV infection, can cause lesions in the mouth and throat that make eating painful.
- *Medications.* The medications given to treat HIV infection, other infections, and cancer often cause anorexia, nausea and vomiting, altered taste sensation, food aversions, and diarrhea.

GI Tract Complications Complications of HIV infection involving the GI tract may result from opportunistic infections, the HIV infection itself, and medications.[28] In addition to the oral infections described previously, infections may develop in the esophagus, stomach, and intestines. Moreover, advanced AIDS is often accompanied by characteristic changes in the small intestinal lining: the villi appear shortened and flattened, and the absorptive area is substantially reduced. ◆ These changes can cause malabsorption, steatorrhea, and diarrhea.

As described earlier, many patients are unable to tolerate the medications used to suppress HIV and develop nausea, vomiting, and diarrhea. Furthermore, the medications that treat the viral, parasitic, and fungal infections in the GI tract contribute to bacterial overgrowth. Thus HIV-infected patients face an extremely high risk of malnutrition due to the combination of intestinal discomfort, bacterial overgrowth, malabsorption, and nutrient losses from vomiting, steatorrhea, and diarrhea.

Neurological Complications Neurological complications may be a consequence of HIV infection, immune suppression, or cancers and infections that target brain tissue.[29] Clinical features include mild to severe dementia; muscle weakness and gait disturbances; and pain, numbness, and tingling in the legs and feet. Neurological impairments are usually more pronounced in the advanced stages of AIDS.

Other Complications Patients with HIV infection can develop anemia due to chronic inflammation, ◆ nutrient malabsorption, blood loss, disturbances in bone marrow function, or medication side effects. HIV infection may also lead to skin disorders (rashes, infections, and cancers), eye diseases (retinal infection and detachment), kidney diseases (nephrotic syndrome and chronic kidney disease), and coronary heart disease.[30]



© Biophoto Associates/Photo Researchers, Inc.

The oral infection *thrush* is easily identified by the characteristic milky white patches that appear on the tongue.

◆ The AIDS-related abnormalities in the intestinal mucosa are sometimes referred to as *HIV enteropathy* (EN-ter-OP-ah-thy).

◆ Reminder: The *anemia of chronic disease* often develops during chronic illness and is characterized by altered iron distribution in tissues and reduced synthesis of red blood cells, among other abnormalities (See Highlight 19).

Treatments for HIV Infection

Although there is no cure for HIV infection, treatments can help to slow its progression, reduce complications, and alleviate pain. The standard treatment for suppressing HIV infection, called *highly active antiretroviral therapy (HAART),* combines three or more antiretroviral drugs.[31] Table 29-9 on p. 914 lists the major drug categories included in antiretroviral therapy and describes the drugs' modes of action. These antiretroviral agents have multiple adverse effects that make their long-term use difficult to tolerate. In addition to the GI effects discussed previously, side effects include skin rashes, headache, anemia, tingling and numbness, hepatitis, pancreatitis, and kidney stones. Thus, although HAART has improved life span and quality of life for many patients, the drug regimens are difficult to adhere to and cause complications that require continual management. The Diet-Drug Interactions feature on p. 914 summarizes the nutrition-related effects of some of the antiretroviral agents and other drugs mentioned in this chapter.

Control of Lipodystrophy Treatment strategies for lipodystrophy are under investigation. Both aerobic activity and resistance training help to reduce abdominal fat, although some patients opt for cosmetic surgery.[32] Patients may be given alternative antiretroviral drugs to alleviate symptoms. Medications may be prescribed to treat abnormal blood lipid levels and insulin resistance.

Control of Anorexia and Wasting Anabolic hormones, appetite stimulants, and regular physical activity have been successful in reversing weight loss and increasing muscle mass in HIV-infected patients.[33] Testosterone and human growth

Kaposi's (cap-OH-seez) **sarcoma:** a common cancer in HIV-infected persons that is characterized by lesions in the skin, lungs, and GI tract.

TABLE 29-9 Antiretroviral Drugs for Treatment of HIV Infection

Category	Examples	Mode of Action
CCR5 antagonist	Maraviroc	CCR5 antagonists prevent HIV from entering cells by blocking a membrane receptor on the host cell.
Fusion inhibitor	Enfuvirtide	Fusion inhibitors prevent HIV from entering cells by binding a viral protein needed for its entry.
Integrase inhibitor	Raltegravir	Integrase inhibitors impair the function of HIV's integrase enzyme, which incorporates viral DNA into the host cell's genome.
Non-nucleoside reverse transcriptase inhibitor (NNRTI)	Delavirdine, efavirenz, nevirapine	NNRTI bind active sites on HIV's reverse transcriptase enzyme, blocking the ability of HIV to produce DNA copies of its genetic material.
Nucleoside reverse transcriptase inhibitor (NRTI)	Didanosine, lamivudine, zidovudine (AZT)	As analogs of the nucleosides needed for DNA synthesis, NRTI impair the ability of HIV's reverse transcriptase enzyme to produce usable copies of DNA.
Protease inhibitor (PI)	Saquinavir, ritonavir, indinavir	PI inhibit HIV's protease enzyme, which cleaves HIV's gene products into usable structural proteins.

Safrin, Antiviral agents, in B. G. Katzung, ed., *Basic and Clinical Pharmacology* (New York: Lange/McGraw-Hill, 2007), pp. 790–818.

DIET-DRUG INTERACTIONS

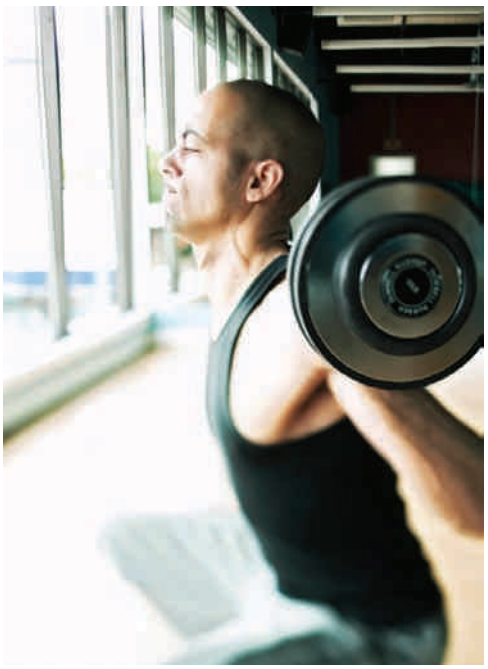
Check this table for notable nutrition-related effects of the medications discussed in this chapter.

	Gastrointestinal Effects	Interactions with Dietary Substances	Metabolic Effects
Appetite stimulants (megestrol acetate, dronabinol)	Nausea, vomiting, diarrhea.	—	Hyperglycemia (megestrol acetate).
Didanosine	Nausea, vomiting, dry mouth, altered taste perception, anorexia, constipation.	Avoid alcohol and aluminum- and magnesium-containing antacids.	Pancreatitis.
Enfuvirtide	Nausea, vomiting, anorexia, diarrhea, constipation.	—	Pancreatitis, increased blood triglycerides.
Methotrexate	Nausea, vomiting, diarrhea, reduced absorption of vitamin B_{12} and calcium.	Milk may reduce methotrexate absorption if the milk and methotrexate are ingested together.	Increased serum uric acid levels, anemia, liver toxicity.
Ritonavir	Nausea, vomiting, altered taste perception, anorexia, diarrhea.	—	Pancreatitis, diabetes, reduced blood levels of copper and zinc; increased levels of triglycerides, liver enzymes, creatine kinase, and uric acid.
Zidovudine (AZT)	Nausea, vomiting, altered taste perception, anorexia, mouth sores, constipation.	—	Anemia, reduced blood levels of copper and zinc.

NOTE: Other antiretroviral drugs that treat HIV infection have gastrointestinal and metabolic side effects; only a few are listed here as examples.

hormone have demonstrated positive effects on nitrogen balance and lean tissue content, especially in combination with resistance training. A regular program of resistance exercise improves muscle mass and strength and corrects some of the metabolic abnormalities (altered blood lipids and insulin resistance) that are common in HIV-infected patients. The medications megestrol acetate and dronabinol (described on p. 907) are sometimes prescribed to stimulate appetite and improve weight gain, although much of the weight increase is attributable to a gain of fat rather than lean tissue.[34]

Alternative Therapies Like cancer patients, people with HIV infection and AIDS are frequently tempted to try unconventional methods of treatment. Although many alternative therapies are harmless, they can be expensive at a time when financial security is of concern. Monitoring patients' use of dietary supplements is essential to reduce the possibility of nutrient-drug and herb-drug interactions.



© Take 2 Productions/Ken Kaminesky/Corbis

Resistance training can help a person with HIV infection maintain muscle mass and strength.

Medical Nutrition Therapy for HIV Infection

Nutrition assessment and counseling should begin as soon as a patient is diagnosed with HIV infection. The initial assessment provides baseline data with which to monitor progress throughout the course of the disease, and it should include an evaluation of body weight and body composition. Follow-up measurements may indicate the need to adjust dietary recommendations and drug therapies.

Weight Maintenance A primary objective of nutrition therapy is to help the patient with HIV infection maintain weight and muscle tissue.[35] Health practitioners should attempt to determine the factors that interfere with the patient's food intake and physical activity, as well as offer suggestions that may help to prevent future weight problems. Some individuals may benefit from a high-kcalorie, high-protein diet. The addition of nutrient-dense snacks, protein or energy bars, and oral supplements can improve intakes. Liquid formulas may be useful for the person who is too tired to eat or prepare meals. If food consumption is difficult, small, frequent feedings may be better tolerated than several large meals. The "How to" on p. 908 provides suggestions for adding energy and protein to the diet.

Vitamins and Minerals Vitamin and mineral needs of people with HIV infections are highly variable, and little information is available concerning specific needs. Because nutrient deficiencies are likely to result from reduced food intake, malabsorption, diet-drug interactions, and nutrient losses, multivitamin-mineral supplements are often recommended. Patients should be cautioned to maintain intakes that are close to DRI recommendations, however, as some studies suggest that micronutrient supplements may have some harmful effects in individuals on antiretroviral drug therapies.[36]

Metabolic Complications As mentioned, patients with HIV infection who are using antiretroviral drugs frequently develop insulin resistance and elevated triglyceride and LDL (low-density lipoprotein) cholesterol levels. Treating these problems often requires both medications and dietary adjustments. Patients should be advised to achieve or maintain a desirable weight, replace saturated fats with monounsaturated and polyunsaturated fats, increase fiber intake, and limit intakes of *trans*-fatty acids, cholesterol, added sugars, and alcohol. Regular physical activity can improve both insulin resistance and blood lipid levels. ◆ If problems persist, alternative antiretroviral medications may be prescribed in an attempt to improve the metabolic abnormalities.

◆ Additional suggestions for managing insulin resistance and hyperlipidemias are available in Chapters 26 and 27, respectively.

Symptom Management The discomfort associated with antiretroviral therapy, opportunistic GI infections, and malabsorption may make food consumption difficult, and problems such as vomiting and diarrhea contribute to fluid and electrolyte losses. The "How to" on p. 910 describes measures that can improve food and fluid intakes and alleviate discomfort in individuals with these problems.

Food Safety The depressed immunity of people with HIV infections places them at extremely high risk of developing foodborne infections. Health practitioners should caution patients about their high susceptibility to foodborne illness and provide detailed instructions about the safe handling and preparation of foods (see Highlight 18). Water can also be a source of foodborne illness and is a common cause of **cryptosporidiosis** in HIV-infected individuals. Because water quality varies throughout the United States, patients should consult their local health departments to determine whether the local tap water is safe to drink. If not, or to take additional safety measures, they should boil drinking water for one minute. Some, but not all, types of filtered and bottled waters are safe.

Enteral and Parenteral Nutrition Support In later stages of illness, people with HIV infections may be unable to consume enough food and may need aggressive nutrition support. Tube feedings are preferred whenever the GI tract is functional; they can be provided at night to supplement oral diets consumed during the day. Parenteral nutrition is reserved for patients who are unable to tolerate enteral nutrition, such as those with GI obstructions that prevent food intake. For individuals with severe malabsorption, orally administered hydrolyzed formulas containing medium-chain triglycerides may be as effective as parenteral nutrition for reversing weight loss and wasting. For either type of feeding, careful measures are necessary to avoid bacterial contamination of nutrient formulas and feeding equipment.

IN SUMMARY

By attacking immune cells, HIV causes progressive damage to immune function and may eventually lead to AIDS. Improved drug therapies have slowed the progression of HIV infection; however, these drugs may promote the HIV-lipodystrophy syndrome, characterized by body fat redistribution, abnormal lipid levels, and insulin resistance. HIV infection is often associated with weight loss and wasting, anorexia, and various complications that affect food intake. Dietary adjustments, resistance training, and medications can help patients maintain their weight and prevent wasting. People with HIV infection must pay strict attention to food safety guidelines to prevent foodborne illnesses. The Case Study provides an opportunity to review the nutritional concerns of a person with HIV infection.

CASE STUDY Financial Planner with HIV Infection

Three years ago, Darrell Meckler, a 34-year-old financial planner, sought medical help when he began feeling run-down and developed a painful white fungal infection over his mouth and tongue. The presence of thrush, recent weight loss, and anemia alerted Mr. Meckler's physician to the possibility of an HIV infection. When Mr. Meckler tested positive for HIV, he and his family and friends were devastated by the news, but those close to him have remained supportive. During the three years since Mr. Meckler began antiretroviral drug therapy, he has maintained his weight but has also developed lipodystrophy and hypertriglyceridemia. Mr. Meckler is 6 feet tall and currently weighs 185 pounds. He occasionally develops diarrhea and sometimes anorexia.

1. Describe lipodystrophy, and discuss its typical pattern in people who have an HIV infection. What adjustments in treatment and lifestyle may be helpful for Mr. Meckler?
2. Describe an appropriate diet for Mr. Meckler. What strategies may improve his problems with diarrhea and anorexia? Suggest reasons why diarrhea and anorexia may develop in people with HIV infections.
3. Explain why an HIV infection can lead to wasting as the disease progresses to the later stages. What recommendations may be helpful for maintaining weight and health if wasting becomes a problem?

cryptosporidiosis (KRIP-toe-spor-ih-dee-OH-sis): a foodborne illness caused by the parasite *Cryptosporidium parvum.*

Clinical Portfolio

CENGAGENOW™
academic.cengage.com/login

1. Consider the nutrition problems that may develop in a 36-year-old woman with a malignant brain tumor that affects her ability to move the right side of her body (including the tongue) and to speak coherently. She is taking a pain medication that makes her nauseated and sleepy. Her expected survival time is only about six months.
   - If she is right-handed, how might her impairment interfere with eating? What suggestions do you have for overcoming this problem?
   - How might her nutrition status be affected by her inability to communicate effectively? What suggestions may help?
   - In what ways might the pain medication she is taking affect her nutrition status?
2. Various types of chronic conditions can lead to weight loss and wasting. For some of these conditions, such as Crohn's disease or celiac disease (Chapter 24), diet is a cornerstone of treatment. For others, such as cancer and HIV infection, nutrition plays a supportive role. What determines whether nutrition plays a primary role or a supportive role in the treatment of disease?

NUTRITION ASSESSMENT CHECKLIST for People with Cancer or HIV Infections

Medical History

Check the medical record to determine:

- Type and stage of cancer
- Stage of HIV infection

Review the medical record for complications that may alter medical nutrition therapy, including:

- Altered organ function
- Altered taste perception
- Anorexia
- Dry mouth and oral infections
- GI symptoms and infections
- Hyperlipidemias
- Insulin resistance
- Malnutrition and wasting

Medications

For patients with cancer or HIV infections:

- Check medications to identify potential diet-drug interactions.
- Recommend the use of antinauseants at mealtime, if needed.
- Ask about the use of dietary supplements, including herbal remedies.

For cancer patients who require chemotherapy:

- Recommend strategies to prevent food aversions.
- Offer suggestions for managing drug-related complications.

For HIV-infected patients using antiretroviral drug therapy:

- Remind patients that some drugs are better absorbed with foods and that others must be taken on an empty stomach.
- Help patients work out a medication schedule that suits their lifestyle and is timed appropriately in regard to food intake.
- Offer suggestions for managing drug-related complications.

Dietary Intake

For patients with poor food intakes and weight loss:

- Determine the reasons for reduced food intake.
- Offer appropriate suggestions to improve food intake.
- Provide interventions before weight loss progresses too far.

For patients with HIV infections who experience weight gain, elevated triglyceride or LDL cholesterol levels, or hyperglycemia:

- Assess the diet for energy, total fat, types of fat, carbohydrates, fiber, and sugars.
- For patients with hyperlipidemias, recommend a diet low in saturated fat, *trans*-fatty acids, and sugars.
- For patients with hyperglycemia, recommend a consistent carbohydrate intake that emphasizes complex carbohydrates.
- Recommend regular physical activity for weight control and for improving blood lipid levels and insulin resistance.

Anthropometric Data

Take baseline height and weight measurements, monitor weight regularly, and suggest dietary adjustments for weight maintenance, if necessary. Remember that body composition may change without affecting body weight. Perform baseline and periodic body composition measurements in HIV-infected patients who are using antiretroviral drug therapy.

Laboratory Tests

Note that albumin and other serum proteins may be reduced in patients with cancer or HIV infections, especially in those experiencing wasting. Check laboratory tests for indications of:

- Anemia
- Dehydration
- Elevated LDL cholesterol levels
- Elevated triglyceride levels
- Hyperglycemia

For patients with HIV infections, evaluate disease progression by checking:

- Helper T cell counts
- Viral load

Physical Signs

Look for physical signs of:

- Dehydration (especially for patients with fever, vomiting, or diarrhea)
- Kaposi's sarcoma
- Oral infections
- Protein-energy malnutrition and wasting

STUDY QUESTIONS

CENGAGENOW™

To assess your understanding of chapter topics, take the Student Practice Test and explore the modules recommended in your Personalized Study Plan. Log on to **academic.cengage.com/login.**

These questions will help you review the chapter. You will find the answers in the discussions on the pages provided.

1. Describe the process of tumor formation. What factors contribute to cancer development? Discuss the dietary factors that may increase or decrease the risk of cancer. (pp. 901–904)
2. What is cancer cachexia? What factors promote its development? (p. 905)
3. Explain how cancer and its treatments can cause alterations in food intake and metabolism, and possibly lead to malnutrition. (p. 905)
4. Discuss the elements of medical nutrition therapy for cancer, as well as strategies that can improve food intake. (pp. 907–910)
5. Explain how HIV is transmitted, and list risk factors associated with an HIV infection. (p. 911)
6. Describe the possible consequences of HIV infection, such as reduced immunity, HIV-lipodystrophy syndrome, wasting, GI complications, neurological complications, and anemia. Explain why an HIV infection often results in anorexia and reduced food intake. (pp. 911–913)
7. Describe how an HIV infection is treated, and discuss the potential complications associated with treatment. Discuss the features of medical nutrition therapy for HIV-infected and AIDS patients. (pp. 913–916)
8. Why are people with HIV infections highly susceptible to foodborne illness? Describe some measures that can be taken to prevent foodborne illness. (p. 916)

These multiple choice questions will help you prepare for an exam. Answers can be found on p. 920.

1. Which of these dietary substances may help to protect against cancer?
   a. alcohol
   b. well-cooked meats, poultry, and fish
   c. animal fats
   d. phytochemicals from fruits and vegetables
2. The metabolic changes that often accompany cancer include all of the following *except:*
   a. increased triglyceride breakdown.
   b. increased protein turnover.
   c. increased muscle protein synthesis.
   d. insulin resistance.
3. An advantage of radiation therapy over chemotherapy is that:
   a. radiation is not damaging to rapidly dividing cells.
   b. irradiation's side effects do not include malnutrition.
   c. radiation can be directed toward the regions affected by cancer.
   d. the radiation used is too weak to damage GI tissues.
4. Although many cancer patients lose weight, which type of cancer is often associated with weight gain?
   a. kidney cancer
   b. breast cancer
   c. colon cancer
   d. lung cancer
5. Oral diets after bone marrow transplants may restrict:
   a. fiber.
   b. carbohydrates.
   c. high-protein foods.
   d. raw fruits and vegetables.
6. HIV can enter and destroy these immune cells:
   a. B cells
   b. helper T cells
   c. natural killer cells
   d. neutrophils
7. HIV-lipodystrophy syndrome may result in all of these changes *except:*
   a. increased abdominal fat.
   b. increased fat in the arms and legs.
   c. fat accumulation at the base of the neck.
   d. hypertriglyceridemia.
8. Mouth sores in people with HIV infections are most frequently due to:
   a. oral infections.
   b. dehydration.
   c. nutrient deficiency.
   d. foodborne illnesses.
9. Megestrol acetate and dronabinol are:
   a. medications used to promote weight gain.
   b. protease inhibitors that fight HIV infection.
   c. medications that treat common opportunistic infections.
   d. anabolic hormones that promote gain of muscle tissue.
10. To prevent cryptosporidiosis, a person with HIV infection may need to:
    a. wash hands carefully before meals.
    b. avoid consuming undercooked meat, poultry, and eggs.
    c. consume a high-kcalorie, high-protein diet
    d. boil drinking water for one minute.

Complementary and Alternative Medicine

© Art Montes De Oca/Taxi/Getty Images

The medical treatments described in the clinical chapters are based upon current scientific understanding of human physiology and biochemistry and are generally supported by well-conducted clinical research. In **conventional medicine,** if a treatment is tested and found to be ineffective, it is eventually abandoned. If a novel therapy is demonstrated by clinical research to be effective and the benefits of using it outweigh its risks, it is incorporated into mainstream medical practice.[1] This highlight examines therapies that have *not* been scientifically validated and are therefore not currently accepted by conventional medical professionals; these therapies fall into a category called **complementary and alternative medicine (CAM).** The accompanying glossary defines related terms.

An estimated 36 percent of adults in the United States use some form of CAM (excluding the use of prayer).[2] CAM is most prevalent among people with chronic, debilitating diseases; for example, 84 percent of AIDS patients reportedly use CAM.[3] Many patients use CAM as an adjunct to conventional medicine—often for symptoms or illnesses that are not sufficiently helped by conventional treatments. CAM therapies remain popular despite the dearth of evidence demonstrating their effectiveness. Reasons for their popularity include consumers' growing interest in self-help measures, the noninvasive nature of many CAM therapies, and the positive interactions consumers have with CAM practitioners.[4]

In response to the enormous popularity of CAM in the United States, in 1998 Congress established the **National Center for Complementary and Alternative Medicine (NCCAM),** which is now one of the 27 institutes that make up the National Institutes of Health (NIH). The missions of NCCAM are to investigate complementary and alternative therapies by funding well-designed scientific studies and to provide authoritative information for consumers and health professionals. If enough evidence is found to support the use of a complementary or alternative therapy, it will likely become a treatment regularly offered by conventional health practitioners.[5]

Defining Complementary and Alternative Medicine

CAM includes a huge variety of approaches, philosophies, and treatments that have not been proven effective for treating disease; some of them are described in the Glossary of Alternative Therapies (p. 923). When these therapies are used in place of conventional medicine, they are called *alternative;* when used together with conventional medicine, they are called *complementary.* The term *alternative* may be misleading in that it inappropriately implies that unproven methods of treatment are valid alternatives to conventional treatments.

Due to substantial consumer interest, health care professionals are finding it necessary to learn about CAM therapies so that they can better communicate with patients regarding their medical care and advise them when an alternative approach conflicts with standard therapy or presents a danger to health. To provide medical students with objective information about CAM, half of U.S. medical schools now offer elective courses about alternative forms of treatment.[6] Physicians who practice **integrative medicine** refer patients for complementary therapies while continuing to provide standard treatments.

GLOSSARY

complementary and alternative medicine (CAM): diverse medical and health care systems, practices, and products that currently are not considered part of conventional medicine; also called *unconventional* or *unorthodox therapies.*

- *Complementary medicine* refers to unconventional therapies that are used *in addition to,* and not simply as a replacement for, conventional medicine.
- *Alternative medicine* refers to unconventional therapies that are used *in place of* conventional medicine.

conventional medicine: diagnosis and treatment of diseases as practiced by a doctor of medicine (M.D.) or doctor of osteopathy (D.O.) and assisted by allied health professionals such as registered nurses, pharmacists, and physical therapists; also called *Western, mainstream,* or *orthodox medicine.*

integrative medicine: medical care that combines mainstream medical treatments and referrals to practitioners of CAM therapies.

National Center for Complementary and Alternative Medicine (NCCAM): a federal agency that researches and provides information about complementary and alternative therapies.

Overview of CAM Therapies

CAM encompasses any and all therapies that are not normally part of conventional medicine. Consequently, the list of CAM approaches includes hundreds of advertised therapies purchased and used by consumers. Unfortunately, CAM has become a marketing buzzword and is used by unscrupulous sellers of worthless treatments.

The NCCAM has classified CAM therapies as shown in Table H29-1 and defined in the Glossary of Alternative Therapies on p. 923. Several popular examples are described in this highlight. Other examples are discussed on the NCCAM website **(http://nccam.nih.gov/health).**

Alternative Medical Systems

Alternative medical systems are based on beliefs that lack the scientific basis of the theories underlying conventional medicine. Virtually all of these alternative systems were developed well over 100 years ago, before our bodies' biochemical and physiological processes were well understood. The alternative forms of diagnoses and treatments may appeal to consumers because the interventions are nontechnical and seem nonthreatening. In general, however, the alternative theories and practices remain rooted in the past and have not been updated to include our current knowledge.

TABLE H29-1 Examples of Complementary and Alternative Medicine

Alternative Medical Systems

- Naturopathic medicine
- Homeopathic medicine
- Traditional Chinese medicine
- Ayurveda

Mind-Body Interventions

- Meditation
- Faith healing (prayer)
- Mental healing (including hypnotherapy)
- Music, art, and dance therapy

Biologically Based Therapies

- Dietary supplements
- Foods and special diets
- Herbal products
- Hormones
- Aromatherapy

Manipulative and Body-Based Methods

- Chiropractic
- Massage therapy
- Osteopathic manipulation
- Reflexology

Energy Therapies

- Biofield therapies (including therapeutic touch, acupuncture, and qi gong)
- Bioelectrical therapies (including electrical and magnetic fields).

Naturopathic Medicine

Naturopathic medicine proposes that a person's natural "life force" can foster self-healing. This life force is allegedly stimulated by certain health-promoting factors and suppressed by excesses and deficiencies. Naturopaths believe that ill health results from an internal disruption rather than from external disease-causing agents. Naturopathic therapies aim to enhance the natural healing powers of the body and may include special diets or fasting, herbal remedies and other dietary supplements, acupuncture, homeopathy, massage, and various other interventions.

Homeopathic Medicine

Homeopathic medicine is based on the dubious theory that "like cures like." Homeopaths believe that a substance that causes a particular set of symptoms can be used to cure a disease that has similar symptoms. Homeopathic remedies are usually substantially diluted in the belief that dilution increases potency, and most remedies are so extremely diluted that the original substance is no longer present. Homeopaths theorize that even though their remedies no longer contain a diluted substance, they still have powerful healing effects because the water structure is somehow altered during the dilution process used to prepare homeopathic medicines. This theory, however, conflicts with scientific understanding of water structure and properties.

Traditional Chinese Medicine

Traditional Chinese medicine (TCM) includes a large number of folk practices that originated in China. TCM is based on the theory that the body has pathways (called *meridians*) that conduct energy (called *qi;* pronounced "chee"). The interrupted flow of qi is believed to cause illness. TCM practices allegedly improve the flow of qi and include acupuncture, qi gong, herbal remedies, dietary practices, and massage. (Acupuncture and qi gong are described in a later section on energy therapies.) Ironically, TCM is used by relatively few in the Chinese population, as Chinese physicians have largely adopted the Western approach to managing illness.[7]

Mind-Body Interventions

Mind-body therapies attempt to improve a person's sense of psychological or spiritual well-being despite the presence of illness. The treatments are also used in the hope of reducing stress, dealing with pain, or lowering blood pressure. Some of these therapies have been incorporated into mainstream medicine for stress reduction or relaxation. For example, **biofeedback** training, in which individuals learn to monitor skin temperature, muscle tension, or brain wave activity while practicing relaxation techniques, is frequently taught by behavioral medicine specialists to

GLOSSARY OF ALTERNATIVE THERAPIES

acupuncture (AK-you-PUNK-chur)**:** a therapy that involves inserting thin needles into the skin at specific anatomical points, allegedly to correct disruptions in the flow of energy within the body.

aromatherapy: inhalation of oil extracts from plants to cure illness or enhance health.

ayurveda: a traditional medical system from India that promotes the use of diet, herbs, meditation, massage, and yoga for preventing and treating illness.

bioelectrical or **bioelectromagnetic therapies:** therapies that involve the unconventional use of electric or magnetic fields to cure illness.

biofeedback: a technique in which individuals are trained to gain voluntary control of certain physiological processes, such as skin temperature or brain wave activity, to help reduce stress and anxiety.

biofield therapies: healing methods based on the belief that illnesses can be healed by manipulating energy fields that purportedly surround and penetrate the body. Examples include *acupuncture, qi gong,* and *therapeutic touch.*

chiropractic (KYE-roh-PRAK-tic)**:** an alternative medical system based on the unproven theory that spinal manipulation can restore health.
- A *subluxation* is a misaligned vertebra or other spinal alteration that may cause illness.
- *Adjustment* is the manipulative therapy practiced by chiropractors.

faith healing: the use of prayer or belief in divine intervention to promote healing.

homeopathic (HO-mee-oh-PATH-ic) **medicine:** a practice based on the theory that "like cures like"; that is, substances believed to cause certain symptoms are prescribed for curing the same symptoms, but are given in extremely diluted amounts.
- **homeo** = like
- **pathos** = suffering

hypnotherapy: a technique that uses hypnosis and the power of suggestion to improve health behaviors, relieve pain, and promote healing.

imagery: the use of mental images of things or events to aid relaxation or promote self-healing.

massage therapy: manual manipulation of muscles to reduce tension, increase blood circulation, improve joint mobility, and promote healing of injuries.

meditation: a self-directed technique of calming the mind and relaxing the body.

naturopathic (NAY-chur-oh-PATH-ic) **medicine:** an approach to medical care using practices alleged to enhance the body's natural healing abilities. Treatments may include a variety of alternative therapies including dietary supplements, herbal remedies, exercise, and homeopathy.

osteopathic (OS-tee-oh-PATH-ic) **manipulation:** a CAM technique performed by a doctor of osteopathy (D.O., or osteopath) that includes deep tissue massage and manipulation of the joints, spine, and soft tissues. A D.O. is a fully trained and licensed medical physician, although osteopathic manipulation has not been proved to be an effective treatment.

qi gong (chee-GUNG)**:** a Chinese system that combines movement, meditation, and breathing techniques and allegedly cures illness by enhancing the flow of qi (energy) within the body.

reflexology: a technique that applies pressure or massage on areas of the hands or feet to allegedly cure disease or relieve pain in other areas of the body; sometimes called *zone therapy.*

therapeutic touch: a technique of passing hands over a patient to purportedly identify energy imbalances and transfer healing power from therapist to patient; also called *laying on of hands.*

traditional Chinese medicine (TCM): an approach to medical care based on the concept that illness can be cured by enhancing the flow of qi (energy) within a person's body. Treatments may include herbal therapies, physical exercises, meditation, acupuncture, and remedial massage.

help patients reduce stress or anxiety. Other techniques to reduce stress and promote relaxation include **meditation,** art and music therapy, and prayer.

The clinical applications of other mind-body therapies are far more questionable. An example is guided **imagery,** in which a person tries to reverse the disease process (for example, shrink a tumor) by using mental pictures. Another example is the use of **faith healing** in place of proven conventional treatments to cure disease.

© Cindy Charles/PhotoEdit, Inc.

Biofeedback training is a stress reduction and relaxation technique.

Biologically Based Therapies

Biological therapies include the use of natural products, such as vitamin supplements, herbal and plant extracts, and special foods. The most popular biological therapy is the use of herbal products, which was discussed in Chapter 19. An overview of some other popular biologically based treatments follows.

Hormones

Some hormones or hormonelike products that are derived from foods are considered dietary supplements and can be sold over the counter. Because the FDA does not regulate these products, there is no way of knowing whether they are safe or effective. Moreover, the amount of active ingredient in a dose, as listed on the label, may not be accurate, and the potential hazards of using

these products are not known. One example of a hormone that is available over the counter is melatonin, a hormone made by the pineal gland and alleged to reverse sleep disorders and prevent jet lag. Another example is the adrenal hormone DHEA (dehydroepiandrosterone), which is promoted to enhance immunity, increase muscle mass, improve memory, and defend against aging.

Glucosamine-Chondroitin Supplements

The use of glucosamine and chondroitin supplements is an example of a CAM therapy that is being considered for adoption by mainstream medicine, depending on the outcome of studies of their safety and effectiveness. Glucosamine and chondroitin are produced in the body and help to maintain joint cartilage. Although study results have been mixed, some clinical trials have found that glucosamine and chondroitin supplements reduced moderate to severe symptoms of osteoarthritis better than a placebo; these findings have prompted some physicians to suggest using these supplements for pain relief.[8] Recent studies have cast doubt on the earlier findings, however, and several trials are still in progress.[9]

Aromatherapy

Aromatherapy is the practice of inhaling aromatic substances derived from plants, called *essential oils.* Aromatherapy allegedly improves health and enhances natural healing processes. Popular examples of essential oils include those from eucalyptus, lavender, peppermint, rosemary, and lemon.

Manipulative and Body-Based Methods

Manipulative interventions include physical touch, forceful movement of different parts of the body, and the application of pressure. Some practitioners maintain that special energy fields are also manipulated during the physical treatment and that proper energy flow induces healing, as described in the later section on energy therapies.

Chiropractic

Chiropractic theory proposes that keeping the nervous system free from obstruction allows the body to heal itself, because the healing process stems from the brain and is conducted via the spinal cord and nerves to all parts of the body. Chiropractors claim to diagnose illnesses by detecting subluxations in the spine, which are variously described as misaligned vertebrae or pinched nerves that allegedly cause subtle interferences within the nervous system. The main treatment is the adjustment, a manual manipulation that is said to correct a subluxation and restore the body's natural healing ability. Although spinal manipulation has mainly been found to be helpful for improving back pain, most chiropractors still assert that chiropractic can cure disease rather than simply relieve symptoms.[10] For example, many chiropractors promote spinal manipulation to treat infectious diseases, prevent cancer, and regulate menstrual periods, even though the nervous system and spinal alignment do not play roles in the pathology of these conditions.

Massage Therapy

Massage therapy is the manipulation of muscle and connective tissue to improve muscle function, reduce pain, or promote relaxation. Massage therapists may also apply heat or cold and give advice about exercises that may improve muscle tone and range of motion. Massage is often integrated into conventional physical therapy, although some massage therapists may incorrectly suggest that massage is a valid treatment for a wide range of medical conditions.

Energy Therapies

Two categories of therapies involve the alleged curative power of "energy." **Biofield therapies** are said to influence the energy that surrounds or pervades the human body, and their proponents claim that an energy therapy can strengthen or restore a person's "energy flow" and induce healing. Acupuncture, qi gong, and therapeutic touch are among the therapies that subscribe to these theories. Note that CAM adherents often use the term *energy* unscientifically and that there is no objective evidence of this sort of energy flow. **Bioelectrical** or **bioelectromagnetic therapies** use electric or magnetic fields to allegedly promote healing; for example, magnets have been marketed with claims that they can improve circulation, reduce inflammation, and speed recovery from injuries.

Acupuncture

Acupuncture, a component of traditional Chinese medicine, is based on the theory that disease is caused by the disrupted flow of qi through the body. Acupuncture allegedly corrects such disruptions and restores health. The practice involves the shallow insertion of stainless steel needles into the skin at designated points on the body, sometimes accompanied by a low-frequency current to produce greater stimulation.

Qi Gong

Qi gong is another therapy originating in China that is said to improve the flow of qi within the body. Qi gong masters allegedly cure disease by releasing energy from their body and passing it to the person being treated. Self-help practices include deep breathing, certain types of physical exercise, and concentration and relaxation techniques.

Therapeutic Touch

Therapeutic touch is based on the premise that the "healing force" of a practitioner can be used to cure disease. Practitioners claim to identify and correct energy imbalances by passing their hands above a patient's body and transferring "excess energy" to the patient.

Is CAM Safe and Effective?

As mentioned earlier, CAM treatments are generally excluded from mainstream medical practice because there is no evidence proving that they are effective for treating the diseases and medical conditions for which they are used. Many consumers think otherwise and seem satisfied that these treatments "work." How is this dichotomy to be explained?

Does CAM Work?

Surveys suggest that consumers perceive their visits to CAM therapists as far more pleasant than their visits to conventional health practitioners. CAM therapists spend more time with patients, are more attentive, and use less invasive interventions.[11] Self-help measures are encouraged, so the consumer has more control over the treatment. The therapies appear to be more "natural" and to have fewer side effects. Possible explanations for "cures" include the following:

- A person may seem cured because of misdiagnosis; that is, the condition diagnosed by the CAM practitioner may not have actually existed.
- The condition may have been self-limiting, or it may have gone into temporary remission after the treatment.
- Undue credit may be inappropriately assigned to the CAM therapy when the improvement was actually due to a previous or concurrent conventional treatment.
- The placebo effect may have had an influence on the course of disease.

The central question remains: Do the CAM therapies merely make people feel better, or do they really get better? This question can be answered only by well-controlled research studies.

Potential Hazards of CAM

One of the attractions of alternative therapies is the assumption that they are safe. Recall, however, the concerns associated with the use of herbal products discussed in Chapter 19, which include the potential toxicity of herbal ingredients, product contamination or adulteration, and interactions with conventional medications. Between 1990 and 1999, the FDA recalled more than 100 dietary supplements due to hazards associated with their use.[12]

Another concern is that use of CAM therapies may delay the use of reliable treatments that have demonstrable benefits.[13] Various reports have described people with treatable medical conditions who suffered permanent disability or death when they were misdiagnosed or improperly treated by CAM practitioners. For example, a rare but well-known risk of spinal cord injury or stroke is associated with a type of cervical manipulation performed by chiropractors.[14] Unfortunately, because most CAM therapies are not regulated or monitored, there are no accurate estimates of their adverse effects.

Working with Patients Who Use CAM

CAM therapies may have consequences that influence the course of a disease and its treatment. Accordingly, it is important that health practitioners routinely inquire about the use of CAM therapies and educate patients about the hazards of postponing or stopping conventional treatment.[15] Patients should also be told about potential interactions between conventional treatments and CAM therapies. Some patients may want to learn about differences between evidence-based medical practices and untested CAM theories and may be interested in the integrative medicine options available.

All alternative therapies have one characteristic in common: their effectiveness is, for the most part, unproven. As mentioned previously, patients often choose alternative therapies because of positive interactions with CAM practitioners. Thus, all health care practitioners should realize that empathizing with patients may go a long way toward winning their trust and improving their compliance with therapy. In addition, health practitioners need to regularly use reliable, objective resources to update their knowledge about unconventional practices so that they can knowledgeably discuss these options with patients.

GLOSSARY OF CELL STRUCTURES

cell: the basic structural unit of all living things.

cell membrane: the thin layer of tissue that surrounds the cell and encloses its contents; made primarily of lipid and protein.

chromosomes: a set of structures within the nucleus of every cell that contains the cell's genetic material, DNA, associated with other materials (primarily proteins).

cytoplasm (SIGH-toh-plazm): the cell contents, except for the nucleus.
- **cyto** = cell
- **plasm** = a form

cytosol: the fluid of cytoplasm; contains water, ions, nutrients, and enzymes.

endoplasmic reticulum (en-doh-PLAZ-mic reh-TIC-you-lum): a complex network of intracellular membranes. The **rough endoplasmic reticulum** is dotted with ribosomes, where protein synthesis takes place. The **smooth endoplasmic reticulum** bears no ribosomes.
- **endo** = inside
- **plasm** = the cytoplasm

Golgi (GOAL-gee) **apparatus:** a set of membranes within the cell where secretory materials are packaged for export.

lysosomes (LYE-so-zomes): cellular organelles; membrane-enclosed sacs of degradative enzymes.
- **lysis** = dissolution

mitochondria (my-toh-KON-dree-uh); singular **mitochondrion:** the cellular organelles responsible for producing ATP aerobically; made of membranes (lipid and protein) with enzymes mounted on them.
- **mitos** = thread (referring to their slender shape)
- **chondros** = cartilage (referring to their external appearance)

nucleus: a major membrane-enclosed body within every cell, which contains the cell's genetic material, DNA, embedded in chromosomes.
- **nucleus** = a kernel

organelles: subcellular structures such as ribosomes, mitochondria, and lysosomes.
- **organelle** = little organ

Cells, Hormones, and Nerves

This appendix is offered as an optional chapter for readers who want to enhance their understanding of how the body coordinates its activities. It presents a brief summary of the structure and function of the body's basic working unit (the cell) and of the body's two major regulatory systems (the hormonal system and the nervous system).

The Cell

The body's organs are made up of millions of cells and of materials produced by them. Each **cell** is specialized to perform its organ's functions, but all cells have common structures (see the accompanying glossary and Figure A-1). Every cell is contained within a **cell membrane.** The cell membrane assists in moving materials into and out of the cell, and some of its special proteins act as "pumps" (described in Chapter 6). Some features of cell membranes, such as microvilli (Chapter 3), permit cells to interact with other cells and with their environments in highly specific ways.

Inside the membrane lies the **cytoplasm,** which is filled with **cytosol,** or cell "fluid." The cytoplasm contains much more than just fluid, though. It is a highly organized system of fibers, tubes, membranes, particles, and subcellular **organelles** as complex as a city. These parts intercommunicate, manufacture and exchange materials, package and prepare materials for export, and maintain and repair themselves.

Within each cell is another membrane-enclosed body, the **nucleus.** Inside the nucleus are the **chromosomes,** which contain the genetic material, DNA. The DNA encodes all the instructions for carrying out the cell's activities. The role of DNA in coding for cell proteins is summarized in Figure 6-7 on p. 188. Chapter 6 also describes the variety of proteins produced by cells and the ways they perform the body's work.

Among the organelles within a cell are ribosomes, mitochondria, and lysosomes. Figure 6-7 briefly refers to the **ribosomes;** they assemble amino acids into proteins, following directions conveyed to them by RNA.

The **mitochondria** are made of intricately folded membranes that bear thousands of highly organized sets of enzymes on their inner and outer surfaces. Mitochondria are crucial to energy metabolism (described in Chapter 7) and muscles conditioned to work aerobically are packed with them. Their presence is implied whenever the TCA cycle and electron transport chain are mentioned because the mitochondria house the needed enzymes.*

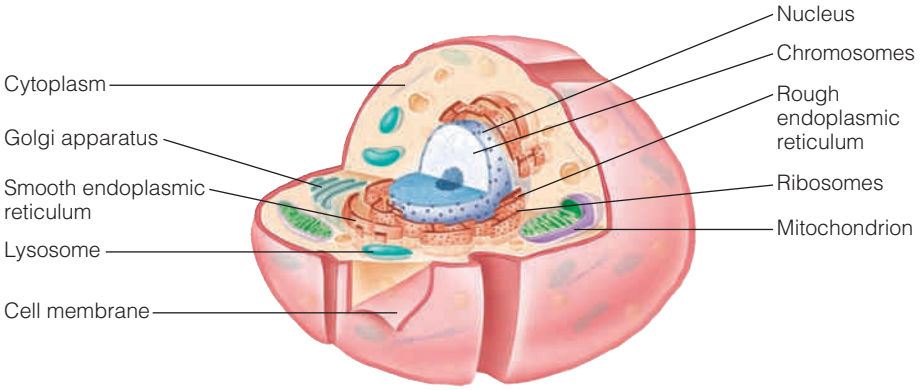
The **lysosomes** are membranes that enclose degradative enzymes. When a cell needs to self-destruct or to digest materials in its surroundings, its lysosomes free their enzymes. Lysosomes are active when tissue repair or remodeling is taking place—for example, in cleaning up infections, healing wounds, shaping embryonic organs, and remodeling bones.

Besides these and other cellular organelles, the cell's cytoplasm contains a highly organized system of membranes, the **endoplasmic reticulum.** The ribosomes may either float free in the cytoplasm or be mounted on these membranes. A membranous surface dotted with ribosomes looks speckled under the microscope and is called "rough" endoplasmic reticulum; such a surface without ribosomes is called "smooth." Some intracellular membranes are organized into tubules that collect cellular materials, merge with the cell membrane, and discharge their contents to the outside of

*For the reactions of glycolysis, the TCA cycle, and the electron transport chain, see Chapter 7 and Appendix C. The reactions of glycolysis take place in the cytoplasm; the conversion of pyruvate to acetyl CoA takes place in the mitochondria, as do the TCA cycle and electron transport chain reactions. The mitochondria then release carbon dioxide, water, and ATP as their end products.

FIGURE A-1 The Structure of a Typical Cell

The cell shown might be one in a gland (such as the pancreas) that produces secretory products (enzymes) for export (to the intestine). The rough endoplasmic reticulum with its ribosomes produces the enzymes; the smooth reticulum conducts them to the Golgi region; the Golgi membranes merge with the cell membrane, where the enzymes can be released into the extracellular fluid.



the cell; these membrane systems are named the **Golgi apparatus,** after the scientist who first described them. The rough and smooth endoplasmic reticula and the Golgi apparatus are continuous with one another, so secretions produced deep in the interior of the cell can be efficiently transported to the outside and released. These and other cell structures enable cells to perform the multitudes of functions for which they are specialized.

The actions of cells are coordinated by both hormones and nerves, as the next sections show. Among the types of cellular organelles are receptors for the hormones delivering instructions that originate elsewhere in the body. Some hormones penetrate the cell and its nucleus and attach to receptors on chromosomes, where they activate certain genes to initiate, stop, speed up, or slow down synthesis of certain proteins as needed. Other hormones attach to receptors on the cell surface and transmit their messages from there. The hormones ◆ are described in the next section; the nerves, in the one following.

The Hormones

A chemical compound—a **hormone**—originates in a gland and travels in the bloodstream. The hormone flows everywhere in the body, but only its target organs respond to it, because only they possess the receptors to receive it.

The hormones, the glands they originate in, and their target organs and effects are described in this section. Many of the hormones you might be interested in are included, but only a few are discussed in detail. Figure A-2 (p. A-4) identifies the glands that produce the hormones, and the accompanying glossary defines the hormones discussed in this section.

Hormones of the Pituitary Gland and Hypothalamus

The anterior pituitary gland ◆ produces the following hormones, each of which acts on one or more target organs and elicits a characteristic response:

- **Adrenocorticotropin (ACTH)** acts on the adrenal cortex, promoting the production and release of its hormones.
- **Thyroid-stimulating hormone (TSH)** acts on the thyroid gland, promoting the production and release of thyroid hormones.
- **Growth hormone (GH)** or **somatotropin** acts on all tissues, promoting growth, fat breakdown, and the formation of antibodies.

◆ The study of hormones and their effects is **endocrinology.**

◆ The **pituitary gland** in the brain has two parts—the **anterior** (front) and the **posterior** (hind).

ribosomes (RYE-boh-zomes): protein-making organelles in cells; composed of RNA and protein.
- **ribo** = containing the sugar ribose (in RNA)
- **some** = body

A Appendix

GLOSSARY OF HORMONES

adrenocorticotropin (ad-REE-noh-KORE-tee-koh-TROP-in) or **ACTH:** a hormone, so named because it stimulates *(trope)* the adrenal cortex. The adrenal gland, like the pituitary, has two parts, in this case an outer portion *(cortex)* and an inner core *(medulla).* The realease of ACTH is mediated by **corticotropin-releasing hormone (CRH).**

aldosterone: a hormone from the adrenal gland involved in blood pressure regulation.
- **aldo** = aldehyde

angiotensin: a hormone involved in blood pressure regulation that is activated by **renin** (REN-in), an enzyme from the kidneys.
- **angio** = blood vessels
- **tensin** = pressure
- **ren** = kidneys

antidiuretic hormone (ADH): the hormone that prevents water loss in urine (also called **vasopressin**).
- **anti** = against
- **di** = through
- **ure** = urine
- **vaso** = blood vessels
- **pressin** = pressure

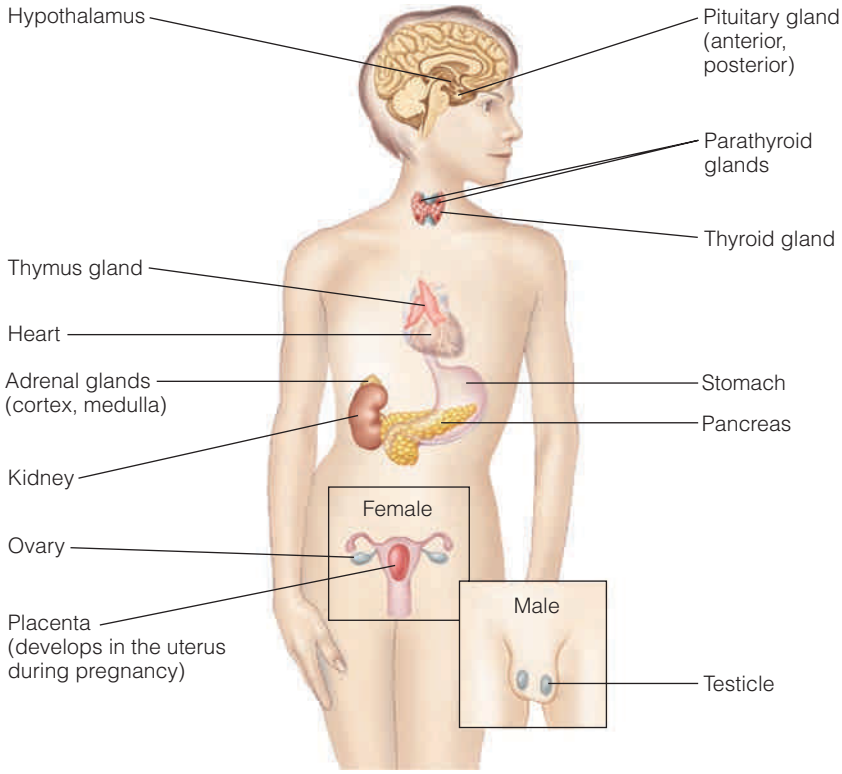
calcitonin (KAL-see-TOH-nin): a hormone secreted by the thyroid gland that regulates (tones) calcium metabolism.

erythropoietin (eh-RITH-ro-POY-eh-tin): a hormone that stimulates red blood cell production.
- **erythro** = red (blood cell)
- **poiesis** = creating (like poetry)

estrogens: hormones responsible for the menstrual cycle and other female characteristics.
- **oestrus** = the egg-making cycle
- **gen** = gives rise to

FIGURE A-2 The Endocrine System

These organs and glands release hormones that regulate body processes. An *endocrine gland* secretes its product directly into *(endo)* the blood; for example, the pancreas cells that produce insulin. An *exocrine gland* secretes its product(s) out *(exo)* to an epithelial surface either directly or through a duct; the sweat glands of the skin and the enzyme-producing glands of the pancreas are both examples. The pancreas is therefore both an endocrine and an exocrine gland.



◆ Hormones that are turned off by their own effects are said to be regulated by **negative feedback.**

follicle-stimulating hormone (FSH): a hormone that stimulates maturation of the ovarian follicles in females and the production of sperm in males. (The ovarian follicles are part of the female reproductive system where the eggs are produced.) The release of FSH is mediated by **follicle-stimulating hormone releasing hormone (FSH–RH).**

glucocorticoids: hormones from the adrenal cortex that affect the body's management of glucose.
- **gluco** = glucose
- **corticoid** = from the cortex

growth hormone (GH): a hormone secreted by the pituitary that regulates the cell division and protein synthesis needed for normal growth (also called **somatotropin**). The release of GH is mediated by **GH-releasing hormone (GHRH)** and **GH-inhibiting hormone (GHIH).**

hormone: a chemical messenger. Hormones are secreted by a variety of endocrine glands in response to altered conditions in the body. Each hormone travels to one or more specific target tissues or organs, where it elicits a specific response to maintain homeostasis.

luteinizing (LOO-tee-in-EYE-zing) **hormone (LH):** a hormone that stimulates ovulation and the development of the corpus luteum (the small tissue that develops from a ruptured ovarian follicle and secretes hormones); so called because the follicle turns yellow as it matures. In men, LH stimulates testosterone secretion. The release of LH is mediated by **luteinizing hormone–releasing hormone (LH–RH).**
- **lutein** = a yellow pigment

- **Follicle-stimulating hormone (FSH)** acts on the ovaries in the female, promoting their maturation, and on the testicles in the male, promoting sperm formation.
- **Luteinizing hormone (LH)** also acts on the ovaries, stimulating their maturation, the production and release of progesterone and estrogens, and ovulation; and on the testicles, promoting the production and release of testosterone.
- **Prolactin,** secreted in the female during pregnancy and lactation, acts on the mammary glands to stimulate their growth and the production of milk.

Each of these hormones has one or more signals that turn it on and another (or others) that turns it off. ◆ Among the controlling signals are several hormones from the hypothalamus:

- **Corticotropin-releasing hormone (CRH),** which promotes release of ACTH, is turned on by stress and turned off by ACTH when enough has been released.
- **TSH-releasing hormone (TRH),** which promotes release of TSH, is turned on by large meals or low body temperature.
- **GH-releasing hormone (GHRH),** which stimulates the release of growth hormone, is turned on by insulin.
- **GH-inhibiting hormone (GHIH** or **somatostatin),** which inhibits the release of GH and interferes with the release of TSH, is turned on by hypoglycemia and/or physical activity and is rapidly destroyed by body tissues so that it does not accumulate.

- **FSH/LH–releasing hormone (FSH/LH–RH)** is turned on in the female by nerve messages or low estrogen and in the male by low testosterone.
- **Prolactin-inhibiting hormone (PIH)** is turned on by high prolactin levels and off by estrogen, testosterone, and suckling (by way of nerve messages).

Let's examine some of these controls. PIH, for example, responds to high prolactin levels (remember, prolactin promotes milk production). High prolactin levels ensure that milk is made and—by calling forth PIH—ensure that prolactin levels don't get too high. But when the infant is suckling—and creating a demand for milk—PIH is not allowed to work (suckling turns off PIH). The consequence: prolactin remains high, and milk production continues. Demand from the infant thus directly adjusts the supply of milk. The need is met through the interaction of the nerves and hormones.

As another example, consider CRH. Stress, perceived in the brain and relayed to the hypothalamus, switches on CRH. On arriving at the pituitary, CRH switches on ACTH. Then ACTH acts on its target organ, the adrenal cortex, which responds by producing and releasing stress hormones. The stress hormones trigger a cascade of events involving every body cell and many other hormones.

The numerous steps required to set the stress response in motion make it possible for the body to fine-tune the response; control can be exerted at each step. These two examples illustrate what the body can do in response to two different stimuli—producing milk in response to an infant's need and gearing up for action in an emergency.

The posterior pituitary gland produces two hormones, each of which acts on one or more target cells and elicits a characteristic response:

- **Antidiuretic hormone (ADH),** or **vasopressin,** acts on the arteries, promoting their contraction, and on the kidneys, preventing water excretion. ADH is turned on whenever the blood volume is low, the blood pressure is low, or the salt concentration of the blood is high (see Chapter 12). It is turned off by the return of these conditions to normal.
- **Oxytocin** acts during late pregnancy on the uterus, inducing contractions, and during lactation on the mammary glands, causing milk ejection. Oxytocin is produced in response to reduced progesterone levels, suckling, or the stretching of the cervix.

Hormones That Regulate Energy Metabolism

Hormones produced by a number of different glands have effects on energy metabolism:

- Insulin from the pancreas beta cells is turned on by many stimuli, including raised blood glucose. It acts on cells to increase glucose and amino acid uptake into them and to promote the secretion of GHRH.
- Glucagon from the pancreas alpha cells responds to low blood glucose and acts on the liver to promote the breakdown of glycogen to glucose, the conversion of amino acids to glucose, and the release of glucose into the blood.
- Thyroxine from the thyroid gland responds to TSH and acts on many cells to increase their metabolic rate, growth, and heat production.
- Norepinephrine and epinephrine ◆ from the adrenal medulla respond to stimulation by sympathetic nerves and produce reactions in many cells that facilitate the body's readiness for fight or flight: increased heart activity, blood vessel constriction, breakdown of glycogen and glucose, raised blood glucose levels, and fat breakdown. Norepinephrine and epinephrine also influence the secretion of the many hormones from the hypothalamus that exert control on the body's other systems.
- Growth hormone (GH) from the anterior pituitary (already mentioned).
- **Glucocorticoids** from the adrenal cortex become active during times of stress and carbohydrate metabolism.

◆ Norepinephrine and epinephrine were formerly called **noradrenalin** and **adrenalin**, respectively.

oxytocin (OCK-see-TOH-sin): a hormone that stimulates the mammary glands to eject milk during lactation and the uterus to contract during childbirth.
- **oxy** = quick
- **tocin** = childbirth

progesterone: the hormone of gestation (pregnancy).
- **pro** = promoting
- **gest** = gestation (pregnancy)
- **sterone** = a steroid hormone

prolactin (proh-LAK-tin): a hormone so named because it promotes *(pro)* the production of milk *(lacto).* The release of prolactin is mediated by **prolactin-inhibiting hormone (PIH).**

relaxin: the hormone of late pregnancy.

somatostatin (GHIH): a hormone that inhibits the release of growth hormone; the opposite of **somatotropin (GH).**
- **somato** = body
- **stat** = keep the same
- **tropin** = make more

testosterone: a steroid hormone from the testicles, or testes. The steroids, as explained in Chapter 5, are chemically related to, and some are derived from, the lipid cholesterol.
- **sterone** = a steroid hormone

thyroid-stimulating hormone (TSH): a hormone secreted by the pituitary that stimulates the thyroid gland to secrete its hormones—thyroxine and triiodothyronine. The release of TSH is mediated by **TSH-releasing hormone (TRH).**

Every body part is affected by these hormones. Each different hormone has unique effects; and hormones that oppose each other are produced in carefully regulated amounts, so each can respond to the exact degree that is appropriate to the condition.

Hormones That Adjust Other Body Balances

Hormones are involved in moving calcium into and out of the body's storage deposits in the bones:

- **Calcitonin** from the thyroid gland acts on the bones, which respond by storing calcium from the bloodstream whenever blood calcium rises above the normal range. It also acts on the kidneys to increase excretion of both calcium and phosphorus in the urine. Calcitonin plays a major role in infants and young children, but is less active in adults.
- Parathyroid hormone (parathormone or PTH) from the parathyroid gland responds to the opposite condition—lowered blood calcium—and acts on three targets: the bones, which release stored calcium into the blood; the kidneys, which slow the excretion of calcium; and the intestine, which increases calcium absorption.
- Vitamin D from the skin and activated in the kidneys acts with parathyroid hormone and is essential for the absorption of calcium in the intestine.

Figure 12-12 on p. 417 diagrams the ways vitamin D and the hormones calcitonin and parathyroid hormone regulate calcium homeostasis.

Another hormone has effects on blood-making activity:

- **Erythropoietin** from the kidneys is responsive to oxygen depletion of the blood and to anemia. It acts on the bone marrow to stimulate the making of red blood cells.

Another hormone is special for pregnancy:

- **Relaxin** from the ovaries is secreted in response to the raised progesterone and estrogen levels of late pregnancy. This hormone acts on the cervix and pelvic ligaments to allow them to stretch so that they can accommodate the birth process without strain.

Other agents help regulate blood pressure:

- **Renin** (an enzyme), from the kidneys, in cooperation with **angiotensin** in the blood responds to a reduced blood supply experienced by the kidneys and acts in several ways to increase blood pressure. Renin and angiotensin also stimulate the adrenal cortex to secrete the hormone aldosterone.
- **Aldosterone,** a hormone from the adrenal cortex, targets the kidneys, which respond by reabsorbing sodium. The effect is to retain more water in the bloodstream—thus, again, raising the blood pressure. Figure 12-3 (on p. 403) in Chapter 12 provides more details.

The Gastrointestinal Hormones

Several hormones are produced in the stomach and intestines in response to the presence of food or the components of food:

- Gastrin from the stomach and duodenum stimulates the production and release of gastric acid and other digestive juices and the movement of the GI contents through the system.
- Cholecystokinin from the duodenum signals the gallbladder and pancreas to release their contents into the intestine to aid in digestion.
- Secretin from the duodenum calls forth acid-neutralizing bicarbonate from the pancreas into the intestine and slows the action of the stomach and its secretion of acid and digestive juices.

- Gastric-inhibitory peptide from the duodenum and jejunum inhibits the secretion of gastric acid and slows the process of digestion.

These hormones are defined and presented in more detail in Chapter 3.

The Sex Hormones

There are three major sex hormones:

- **Testosterone** from the testicles is released in response to LH (described earlier) and acts on all the tissues that are involved in male sexuality, promoting their development and maintenance.
- **Estrogens** from the ovaries are released in response to both FSH and LH and act similarly in females.
- **Progesterone** from the ovaries' corpus luteum and from the placenta acts on the uterus and mammary glands, preparing them for pregnancy and lactation.

This brief description of the hormones and their functions should suffice to provide an awareness of the enormous impact these compounds have on body processes. The other overall regulating agency is the nervous system.

The Nervous System

The nervous system has a central control system that can evaluate information about conditions within and outside the body, and a vast system of wiring that receives information and sends instructions. The control unit is the brain and spinal cord, called the **central nervous system;** and the vast complex of wiring between the center and the parts is the **peripheral nervous system.** The smooth functioning that results from the system's adjustments to changing conditions is homeostasis.

The nervous system has two general functions: it controls voluntary muscles in response to sensory stimuli from them, and it controls involuntary, internal muscles and glands in response to nerve-borne and chemical signals about their status. In fact, the nervous system is best understood as two systems that use the same or similar pathways to receive and transmit their messages. The **somatic nervous system** controls the voluntary muscles; the **autonomic nervous system** controls the internal organs.

When scientists were first studying the autonomic nervous system, they noticed that when something hurt one organ of the body, some of the other organs reacted as if in sympathy for the afflicted one. They therefore named the nerve network they were studying the sympathetic nervous system. The term is still used today to refer to that branch of the autonomic nervous system that responds to pain and stress. The other branch is called the parasympathetic nervous system. (Think of the sympathetic branch as the responder when homeostasis needs restoring and the parasympathetic branch as the commander of function during normal times.) Both systems transmit their messages through the brain and spinal cord. Nerves of the two branches travel side by side along the same pathways to transmit their messages, but they oppose each other's actions (see Figure A-3 on p. A-8).

An example will show how the sympathetic and parasympathetic nervous systems work to maintain homeostasis. When you go outside in cold weather, your skin's temperature receptors send "cold" messages to the spinal cord and brain. Your conscious mind may intervene at this point to tell you to zip your jacket, but let's say you have no jacket. Your sympathetic nervous system reacts to the external stressor, the cold. It signals your skin-surface capillaries to shut down so that your blood will circulate deeper in your tissues, where it will conserve heat. Your sympathetic nervous system also signals involuntary contractions of the small muscles just under the skin surface. The product of these muscle contractions is heat, and the visible result is goose bumps. If these measures do not raise your body temperature enough, then the sympathetic nerves signal your large muscle groups

GLOSSARY OF NERVOUS SYSTEM

autonomic nervous system: the division of the nervous system that controls the body's automatic responses. Its two branches are the **sympathetic** branch, which helps the body respond to stressors from the outside environment, and the **parasympathetic** branch, which regulates normal body activities between stressful times.
• **autonomos** = self-governing

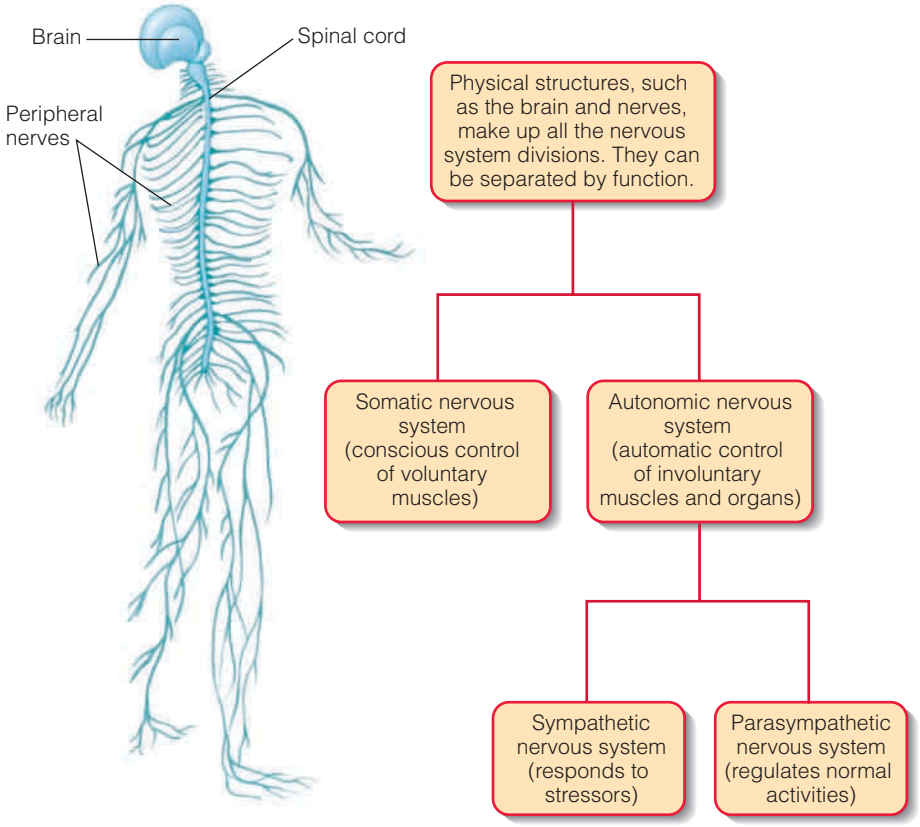
central nervous system: the central part of the nervous system; the brain and spinal cord.

peripheral (puh-RIFF-er-ul) **nervous system:** the peripheral (outermost) part of the nervous system; the vast complex of wiring that extends from the central nervous system to the body's outermost areas. It contains both somatic and autonomic components.

somatic (so-MAT-ick) **nervous system:** the division of the nervous system that controls the voluntary muscles, as distinguished from the autonomic nervous system, which controls involuntary functions.
• **soma** = body

FIGURE A-3 The Organization of the Nervous System

The brain and spinal cord evaluate information about conditions within and outside the body, and the peripheral nerves receive information and send instructions.



to shiver; the contractions of these large muscles produce still more heat. All of this activity helps to maintain your homeostasis (with respect to temperature) under conditions of external extremes (cold) that would throw it off balance. The cold was a stressor; the body's response was resistance.

Now let's say you come in and sit by a fire and drink hot cocoa. You are warm and no longer need all that sympathetic activity. At this point, your parasympathetic nerves take over; they signal your skin-surface capillaries to dilate again, your goose bumps to subside, and your muscles to relax. Your body is back to normal. This is recovery.

Putting It Together

The hormonal and nervous systems coordinate body functions by transmitting and receiving messages. The point-to-point messages of the nervous system travel through a central switchboard (the spinal cord and brain), whereas the messages of the hormonal system are broadcast over the airways (the bloodstream), and any organ with the appropriate receptors can pick them up. Nerve impulses travel faster than hormonal messages do—although both are remarkably swift. Whereas your brain's command to wiggle your toes reaches the toes within a fraction of a second and stops as quickly, a gland's message to alter a body condition may take several seconds or minutes to get started and may fade away equally slowly.

Together, the two systems possess every characteristic a superb communication network needs: varied speeds of transmission, along with private communication lines or public broadcasting systems, depending on the needs of the moment. The hormonal system, together with the nervous system, integrates the whole body's functioning so that all parts act smoothly together.

Basic Chemistry Concepts

This appendix is intended to provide the background in basic chemistry you need to understand the nutrition concepts presented in this book. Chemistry is the branch of natural science that is concerned with the description and classification of **matter,** the changes that matter undergoes, and the **energy** associated with these changes. The accompanying glossary defines matter, energy, and other related terms.

CONTENTS

Matter: The Property of Atoms
Chemical Bonding
Formation of Ions
Water, Acids, and Bases
Chemical Reactions
Formation of Free Radicals

GLOSSARY

atoms: the smallest components of an element that have all of the properties of the element.

compound: a substance composed of two or more different atoms—for example, water (H_2O).

element: a substance composed of atoms that are alike—for example, iron (Fe).

energy: the capacity to do work.

matter: anything that takes up space and has mass.

molecule: two or more atoms of the same or different elements joined by chemical bonds. Examples are molecules of the element oxygen, composed of two oxygen atoms (O_2), and molecules of the compound water, composed of two hydrogen atoms and one oxygen atom (H_2O).

Matter: The Properties of Atoms

Every substance has physical and chemical properties that distinguish it from all other substances and thus give it a unique identity. The physical properties include such characteristics as color, taste, texture, and odor, as well as the temperatures at which a substance changes its state (from a solid to a liquid or from a liquid to a gas) and the weight of a unit volume (its density). The chemical properties of a substance have to do with how it reacts with other substances or responds to a change in its environment so that new substances with different sets of properties are produced.

A physical change does not change a substance's chemical composition. The three physical states—ice, water, and steam—all consist of two hydrogen atoms and one oxygen atom bound together. In contrast, a chemical change occurs when an electric current passes through water. The water disappears, and two different substances are formed: hydrogen gas, which is flammable, and oxygen gas, which supports life.

Substances: Elements and Compounds

The smallest part of a substance that can exist separately without losing its physical and chemical properties is a **molecule.** If a molecule is composed of **atoms** that are alike, the substance is an **element** (for example, O_2). If a molecule is composed of two or more different kinds of atoms, the substance is a **compound** (for example, H_2O).

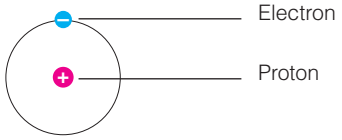
Just over 100 elements are known, and these are listed in Table B-1. A familiar example is hydrogen, whose molecules are composed only of hydrogen atoms linked together in pairs (H_2). On the other hand, over a million compounds are known. An example is the sugar glucose. Each of its molecules is composed of 6 carbon, 6 oxygen, and 12 hydrogen atoms linked together in a specific arrangement (as described in Chapter 4).

The Nature of Atoms

Atoms themselves are made of smaller particles. Within the atomic nucleus are protons (positively charged particles), and surrounding the nucleus are electrons (negatively charged particles). The number of protons (+) in the nucleus of an atom determines the number of electrons (−) around it. The positive charge on a proton is equal to the negative charge on an electron, so the charges cancel each other out and leave the atom neutral to its surroundings.

The nucleus may also include neutrons, subatomic particles that have no charge. Protons and neutrons are of equal mass, and together they give an atom its weight. Electrons bond atoms together to make molecules, and they are involved in chemical reactions.

Each type of atom has a characteristic number of protons in its nucleus. The hydrogen atom is the simplest of all. It possesses a single proton, with a single electron associated with it:



Hydrogen atom (H), atomic number 1.

Just as hydrogen always has one proton, helium always has two, lithium three, and so on. The atomic number of each element is the number of protons in the nucleus of that atom, and this never changes in a chemical reaction; it gives the atom its identity. The atomic numbers for the known elements are listed in Table B-1.

TABLE B-1 Chemical Symbols for the Elements

Key: Elements found in energy-yielding nutrients, vitamins, and water; Major minerals; Trace minerals

Number of Protons (Atomic Number)	Element	Number of Electrons in Outer Shell	Number of Protons (Atomic Number)	Element	Number of Electrons in Outer Shell
1	Hydrogen (H)	1			
2	Helium (He)	2	57	Lanthanum (La)	2
3	Lithium (Li)	1	58	Cerium (Ce)	2
4	Beryllium (Be)	2	58	Cerium (Ce)	2
5	Boron (B)	3	58	Cerium (Ce)	2
6	Carbon (C)	4	60	Neodymium (Nd)	2
7	Nitrogen (N)	5	61	Promethium (Pm)	2
8	Oxygen (O)	6	62	Samarium (Sm)	2

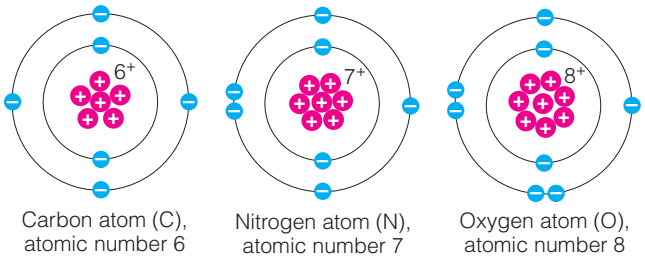
Besides hydrogen, the atoms most common in living things are carbon (C), nitrogen (N), and oxygen (O), whose atomic numbers are 6, 7, and 8, respectively. Their structures are more complicated than that of hydrogen, but each of them possesses the same number of electrons as there are protons in the nucleus. These electrons are found in orbits, or shells (shown below).



In these and all diagrams of atoms that follow, only the protons and electrons are shown. The neutrons, which contribute only to atomic weight, not to charge, are omitted.

The most important structural feature of an atom for determining its chemical behavior is the number of electrons in its outermost shell. The first, or innermost, shell is full when it is occupied by two electrons; so an atom with two or more electrons has a filled first shell. When the first shell is full, electrons begin to fill the second shell.

The second shell is completely full when it has eight electrons. A substance that has a full outer shell tends not to enter into chemical reactions. Atomic number 10, neon, is a chemically inert substance because its outer shell is complete. Fluorine, atomic number 9, has a great tendency to draw an electron from other substances to complete its outer shell, and thus it is highly reactive. Carbon has a half-full outer shell, which helps explain its great versatility; it can combine with other elements in a variety of ways to form a large number of compounds.

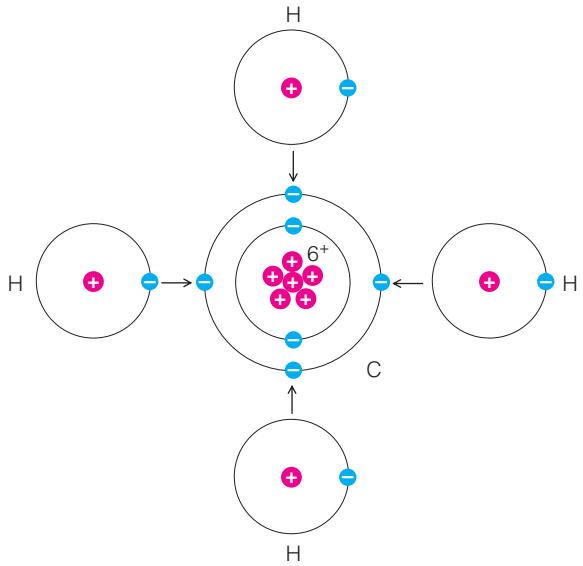
Atoms seek to reach a state of maximum stability or of lowest energy in the same way that a ball will roll down a hill until it reaches the lowest place. An atom achieves a state of maximum stability:

- By gaining or losing electrons to either fill or empty its outer shell.
- By sharing its electrons with other atoms and thereby completing its outer shell.

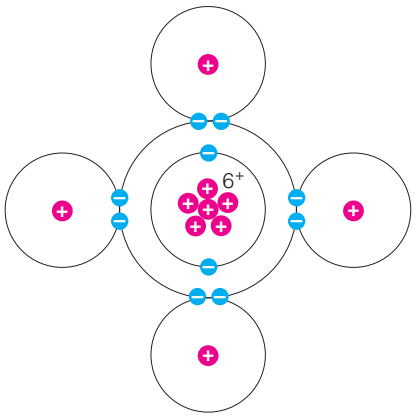
The number of electrons determines how the atom will chemically react with other atoms. The atomic number, not the weight, is what gives an atom its chemical nature.

Chemical Bonding

Atoms often complete their outer shells by sharing electrons with other atoms. In order to complete its outer shell, a carbon atom requires four electrons. A hydrogen atom requires one. Thus, when a carbon atom shares electrons with four hydrogen atoms, each completes its outer shell (as shown in the next column). Electron sharing binds the atoms together and satisfies the conditions of maximum stability for the molecule. The outer shell of each atom is complete, since hydrogen effectively has the required two electrons in its first (outer) shell, and carbon has eight electrons in its second (outer) shell; and the molecule is electrically neutral, with a total of ten protons and ten electrons.

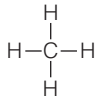


When a carbon atom shares electrons with four hydrogen atoms, a methane molecule is made.



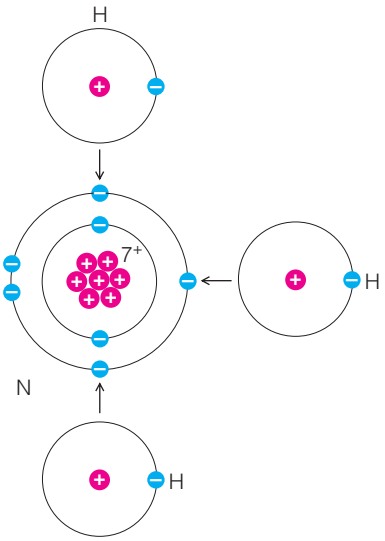
The chemical formula for methane is CH_4. Note that by sharing electrons, every atom achieves a filled outer shell.

Bonds that involve the sharing of electrons, like the bonds between carbon and the four hydrogens, are the most stable kind of association that atoms can form with one another. These bonds are called covalent bonds, and the resulting combination of atoms are called molecules. A single pair of shared electrons forms a single bond. A simplified way to represent a single bond is with a single line. Thus the structure of methane (CH_4) could be represented like this:

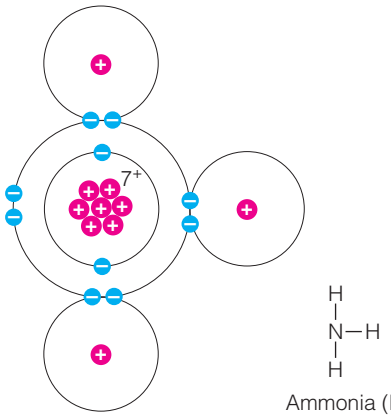


Methane (CH_4)

Similarly, one nitrogen atom and three hydrogen atoms can share electrons to form one molecule of ammonia (NH_3):



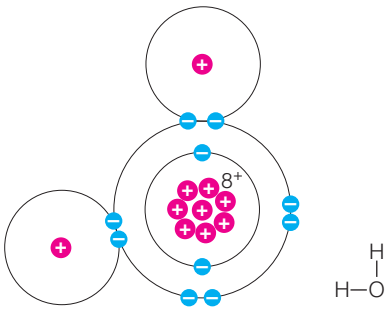
When a nitrogen atom shares electrons with three hydrogen atoms, an ammonia molecule is made.



Ammonia (NH_3)

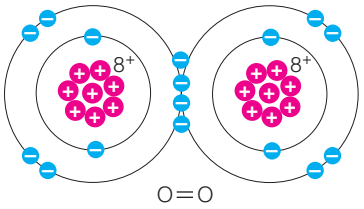
The chemical formula for ammonia is NH_3. Count the electrons in each atom's outer shell to confirm that it is filled.

One oxygen atom may be bonded to two hydrogen atoms to form one molecule of water (H_2O):



Water molecule (H_2O)

When two oxygen atoms form a molecule of oxygen, they must share two pairs of electrons. This double bond may be represented as two single lines:



Oxygen molecule (O_2)

Small atoms form the tightest, most stable bonds. H, O, N, and C are the smallest atoms capable of forming one, two, three, and four electron-pair bonds respectively. This is the basis for the statement in Chapter 4 that in drawings of compounds containing these atoms, hydrogen must always have one, oxygen two, nitrogen three, and carbon four bonds radiating to other atoms:

The stability of the associations between these small atoms and the versatility with which they can combine make them very common in living things. Interestingly, all cells, whether they come from animals, plants, or bacteria, contain the same elements in very nearly the same proportions. The elements commonly found in living things are shown in Table B-2.

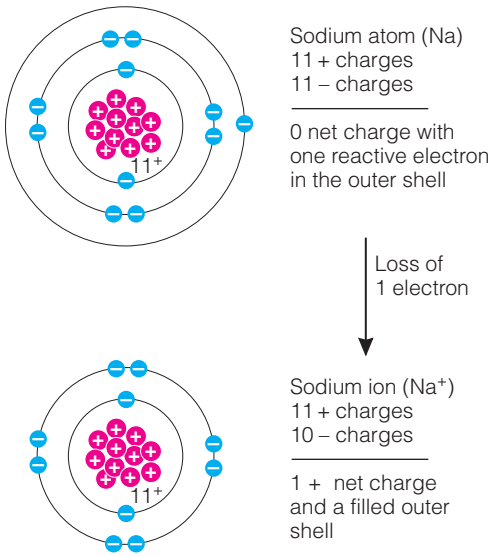
TABLE B-2 Elemental Composition of the Human Body

Element	Chemical Symbol	By Weight (%)
Oxygen	O	65
Carbon	C	18
Hydrogen	H	10
Nitrogen	N	3
Calcium	Ca	1.5
Phosphorus	P	1.0
Potassium	K	0.4
Sulfur	S	0.3
Sodium	Na	0.2
Chloride	Cl	0.1
Magnesium	Mg	0.1
Total		99.6[a]

[a]The remaining 0.40 percent by weight is contributed by the trace elements: chromium (Cr), copper (Cu), zinc (Zn), selenium (Se), molybdenum (Mo), fluorine (F), iodine (I), manganese (Mn), and iron (Fe). Cells may also contain variable traces of some of the following: boron (B), cobalt (Co), lithium (Li), strontium (Sr), aluminum (Al), silicon (Si), lead (Pb), vanadium (V), arsenic (As), bromine (Br), and others.

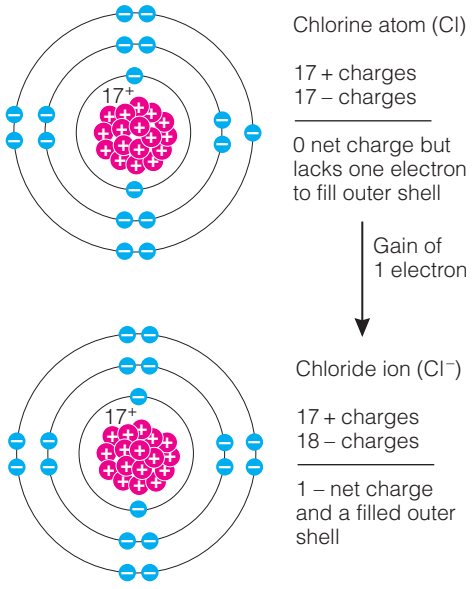
Formation of Ions

An atom such as sodium (Na, atomic number 11) cannot easily fill its outer shell by sharing. Sodium possesses a filled first shell of two electrons and a filled second shell of eight; there is only one electron in its outermost shell:

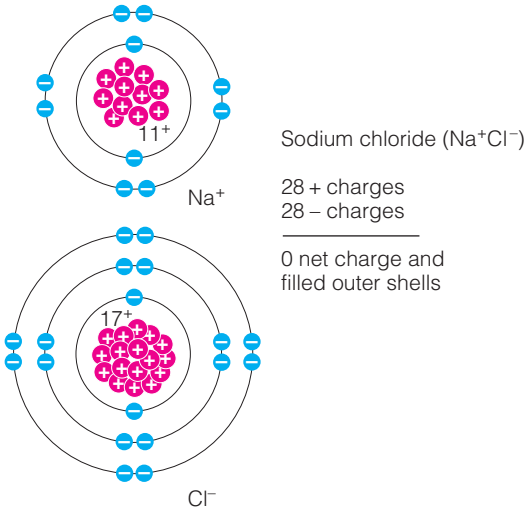


If sodium loses this electron, it satisfies one condition for stability: a filled outer shell (now its second shell counts as the outer shell). However, it is not electrically neutral. It has 11 protons (positive) and only 10 electrons (negative). It therefore has a net positive charge. An atom or molecule that has lost or gained one or more electrons and so is electrically charged is called an ion.

An atom such as chlorine (Cl, atomic number 17), with seven electrons in its outermost shell, can share electrons to fill its outer shell, or it can gain one electron to complete its outer shell and thus give it a negative charge:



A positively charged ion such as sodium ion (Na^+) is called a cation; a negatively charged ion such as a chloride ion (Cl^-) is called an anion. Cations and anions attract one another to form salts:



With all its electrons, sodium is a shiny, highly reactive metal; chlorine is the poisonous greenish yellow gas that was used in World War I. But after sodium and chlorine have transferred electrons, they form the stable white salt familiar to you as table salt, or sodium chloride (Na^+Cl^-). The dramatic difference illustrates how profoundly the electron arrangement can influence the nature of a substance. The wide distribution of salt in nature attests to the stability of the union between the ions. Each meets the other's needs (a good marriage).

When dry, salt exists as crystals; its ions are stacked very regularly into a lattice, with positive and negative ions alternating in a three-dimensional checkerboard structure. In water, however, the salt quickly dissolves, and its ions separate from one another, forming an electrolyte solution in which they move about freely. Covalently bonded molecules rarely dissociate like this in a water solution. The most common exception is when they behave like acids and release H^+ ions, as discussed in the next section.

An ion can also be a group of atoms bound together in such a way that the group has a net charge and enters into reactions as a single unit. Many such groups are active in the fluids of the body. The bicarbonate ion is composed of five atoms—one H, one C, and three Os—and has a net charge of -1 (HCO_3^-). Another important ion of this type is a phosphate ion with one H, one P, and four O, and a net charge of -2 (HPO_4^{-2}).

Whereas many elements have only one configuration in the outer shell and thus only one way to bond with other elements, some elements have the possibility of varied configurations. Iron is such an element. Under some conditions iron loses two electrons, and under other circumstances it loses

three. If iron loses two electrons, it then has a net charge of +2, and we call it ferrous iron (Fe^{++}). If it donates three electrons to another atom, it becomes the +3 ion, or ferric iron (Fe^{+++}).

Ferrous iron (Fe^{++}) (had 2 outer-shell electrons but has lost them)	Ferric iron (Fe^{+++}) (had 3 outer-shell electrons but has lost them)
26 + charges	26 + charges
24 − charges	23 − charges
2 + net charge	3 + net charge

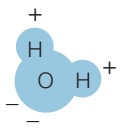
Remember that a positive charge on an ion means that negative charges—electrons—have been lost and not that positive charges have been added to the nucleus.

Water, Acids, and Bases

Water

The water molecule is electrically neutral, having equal numbers of protons and electrons. When a hydrogen atom shares its electron with oxygen, however, that electron will spend most of its time closer to the positively charged oxygen nucleus. This leaves the positive proton (nucleus of the hydrogen atom) exposed on the outer part of the water molecule. We know, too, that the two hydrogens both bond toward the same side of the oxygen. These two facts explain why water molecules are polar: they have regions of more positive and more negative charge.

Polar molecules like water are drawn to one another by the attractive forces between the positive polar areas of one and the negative poles of another. These attractive forces, sometimes known as polar bonds or hydrogen bonds, occur among many molecules and also within the different parts of single large molecules. Although very weak in comparison with covalent bonds, polar bonds may occur in such abundance that they become exceedingly important in determining the structure of such large molecules as proteins and DNA.

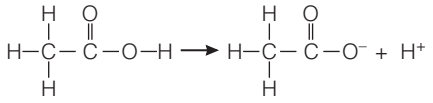


This diagram of the polar water molecule shows displacement of electrons toward the O nucleus; thus the negative region is near the O and the positive regions are near the H atoms.

Water molecules have a slight tendency to ionize, separating into positive (H^+) and negative (OH^-) ions. In pure water, a small but constant number of these ions is present, and the number of positive ions exactly equals the number of negative ions.

Acid

An acid is a substance that releases H^+ ions (protons) in a water solution. Hydrochloric acid (HCl^-) is such a substance because it dissociates in a water solution into H^+ and Cl^- ions. Acetic acid is also an acid because it dissociates in water to acetate ions and free H^+:



Acetic acid dissociates into an acetate ion and a hydrogen ion.

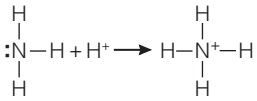
The more H^+ ions released, the stronger the acid.

pH

Chemists define degrees of acidity by means of the pH scale, which runs from 0 to 14. The pH expresses the concentration of H^+ ions: a pH of 1 is extremely acidic, 7 is neutral, and 13 is very basic. There is a tenfold difference in the concentration of H^+ ions between points on this scale. A solution with pH 3, for example, has ten times as many H^+ ions as a solution with pH 4. At pH 7, the concentrations of free H^+ and OH^- are exactly the same—1/10,000,000 moles per liter (1027 moles per liter).* At pH 4, the concentration of free H^+ ions is 1/10,000 (1024) moles per liter. This is a higher concentration of H^+ ions, and the solution is therefore acidic. Figure 3-6 on p. 77 presents the pH scale.

Bases

A base is a substance that can combine with H^+ ions, thus reducing the acidity of a solution. The compound ammonia is such a substance. The ammonia molecule has two electrons that are not shared with any other atom; a hydrogen ion (H^+) is just a naked proton with no shell of electrons at all. The proton readily combines with the ammonia molecule to form an ammonium ion; thus a free proton is withdrawn from the solution and no longer contributes to its acidity. Many compounds containing nitrogen are important bases in living systems. Acids and bases neutralize each other to produce substances that are neither acid nor base.



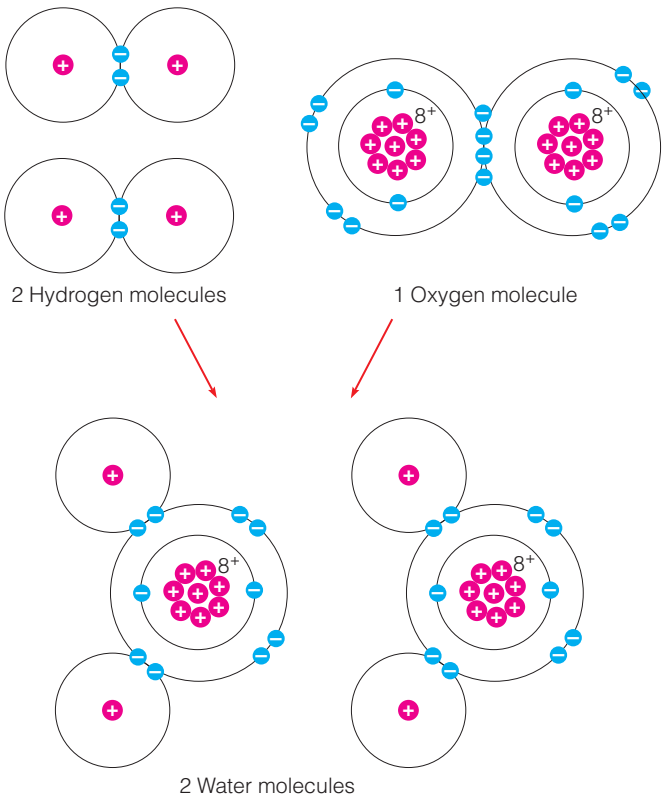
Ammonia captures a hydrogen ion from water. The two dots here represent the two electrons not shared with another atom. These dots are ordinarily not shown in chemical structure drawings. Compare this drawing with the earlier diagram of an ammonia molecule (p. B-4).

Chemical Reactions

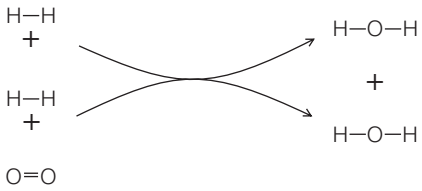
A chemical reaction, or chemical change, results in the breakdown of substances and the formation of new ones. Almost all such reactions involve a change in the bonding of atoms. Old bonds are broken, and new ones are formed. The nuclei of atoms are never involved in chemical reactions—only their

*A mole is a certain number (about 6×10^{23}) of molecules. The pH of a solution is defined as the negative logarithm of the hydrogen ion concentration of the solution. Thus, if the concentration is 10^{-2} (moles per liter), the pH is 2; if 10^{-8}, the pH is 8; and so on.

Diagrams:



Structures:



Formulas:

$2H_2 + O_2 \longrightarrow 2H_2O$

Hydrogen and oxygen react to form water.

outer-shell electrons take part. At the end of a chemical reaction, the number of atoms of each type is always the same as at the beginning. For example, two hydrogen molecules ($2H_2$) can react with one oxygen molecule (O_2) to form two water molecules ($2H_2O$). In this reaction two substances (hydrogen and oxygen) disappear, and a new one (water) is formed, but at the end of the reaction there are still four H atoms and two O atoms, just as there were at the beginning. Because the atoms are now linked in a different way, their characteristics or properties have changed.

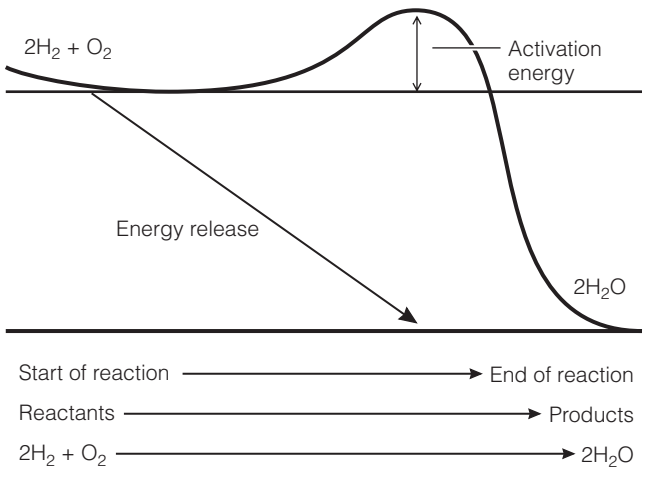
In many instances chemical reactions involve not the relinking of molecules but the exchanging of electrons or protons among them. In such reactions the molecule that gains one or more electrons (or loses one or more hydrogen ions) is said to be reduced; the molecule that loses electrons (or gains protons) is oxidized. A hydrogen ion is equivalent to a proton. Oxidation and reduction reactions take place simultaneously because an electron or proton that is lost by one molecule is accepted by another. The addition of an atom of oxygen is also oxidation because oxygen (with six electrons in the outer shell) accepts two electrons in becoming bonded. Oxidation, then, is loss of electrons, gain of protons, or addition of oxygen (with six electrons); reduction is the opposite—gain of electrons, loss of protons, or loss of oxygen. The addition of hydrogen atoms to oxygen to form water can thus be described as the reduction of oxygen *or* the oxidation of hydrogen.

If a reaction results in a net increase in the energy of a compound, it is called an endergonic, or ''uphill,'' reaction (energy, *erg,* is added into, *endo,* the compound). An example is the chief result of photosynthesis, the making of sugar in a plant from carbon dioxide and water using the energy of sunlight. Conversely, the oxidation of sugar to carbon dioxide and water is an exergonic, or ''downhill,'' reaction because the end products have less energy than the starting products. Oftentimes, but not always, reduction reactions are endergonic, resulting in an increase in the energy of the products. Oxidation reactions often, but not always, are exergonic.

Chemical reactions tend to occur spontaneously if the end products are in a lower energy state and therefore are more stable than the reacting compounds. These reactions often give off energy in the form of heat as they occur. The generation of heat by wood burning in a fireplace and the maintenance of human body warmth both depend on energy-yielding chemical reactions. These downhill reactions occur easily, although they may require some activation energy to get them started, just as a ball requires a push to start rolling.

Uphill reactions, in which the products contain more energy than the reacting compounds started with, do not occur until an energy source is provided. An example of such an energy source is the sunlight used in photosynthesis, where carbon dioxide and water (low-energy compounds) are combined to form the sugar glucose (a higher-energy compound). Another example is the use of the energy in glucose to combine two low-energy compounds in the body into the high-energy

Energy change as reaction occurs

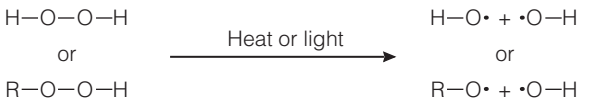


compound ATP (see Chapter 7). The energy in ATP may be used to power many other energy-requiring, uphill reactions. Clearly, any of many different molecules can be used as a temporary storage place for energy.

Neither downhill nor uphill reactions occur until something sets them off (activation) or until a path is provided for them to follow. The body uses enzymes as a means of providing paths and controlling chemical reactions (see Chapter 6). By controlling the availability and the action of its enzymes, the cells can "decide" which chemical reactions to prevent and which to promote.

Formation of Free Radicals

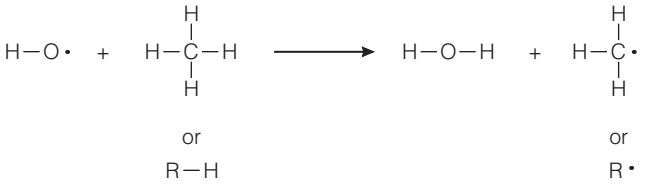
Normally, when a chemical reaction takes place, bonds break and re-form with some redistribution of atoms and rearrangement of bonds to form new, stable compounds. Normally, bonds don't split in such a way as to leave a molecule with an odd, unpaired electron. When they do, free radicals are formed. Free radicals are highly unstable and quickly react with other compounds, forming more free radicals in a chain reaction. A cascade may ensue in which many highly reactive radicals are generated, resulting finally in the disruption of a living structure such as a cell membrane.



Hydrogen peroxide or any hydroperoxide (R is any carbon chain with appropriate numbers of H)

Free radical

Free radicals are formed. The dots represent single electrons that are available for sharing (the atom needs another electron to fill its outer shell).



Free radical

Compound with weak bond (perhaps an unsaturated fatty acid)

New stable compound (water or an alcohol)

Free radical

Free radicals destroy biological compounds. The free radical attacks a weak bond in a biological compound, disrupting it and forming a new stable molecule and another free radical. This free radical can attack another biological compound, and so on.

Oxidation of some compounds can be induced by air at room temperature in the presence of light. Such reactions are thought to take place through the formation of compounds called peroxides:

Peroxides:

H—O—O—H	Hydrogen peroxide
R—O—O—H	Hydroperoxides (R is any carbon chain with appropriate numbers of H)
R—O—O—R	Peroxide

Some peroxides readily disintegrate into free radicals, initiating chain reactions like those just described.

Free radicals are of special interest in nutrition because the antioxidant properties of vitamins C and E as well as beta-carotene and the mineral selenium are thought to protect against the destructive effects of these free radicals (see Highlight 11). For example, vitamin E on the surface of the lungs reacts with, and is destroyed by, free radicals, thus preventing the radicals from reaching underlying cells and oxidizing the lipids in their membranes.

Biochemical Structures and Pathways

The diagrams of nutrients presented here are meant to enhance your understanding of the most important organic molecules in the human diet. Following the diagrams of nutrients are sections on the major metabolic pathways mentioned in Chapter 7—glycolysis, fatty acid oxidation, amino acid degradation, the TCA cycle, and the electron transport chain—and a description of how alcohol interferes with these pathways. Discussions of the urea cycle and the formation of ketone bodies complete the appendix.

Carbohydrates

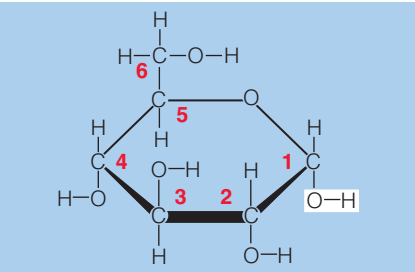
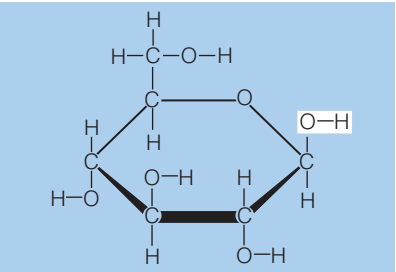
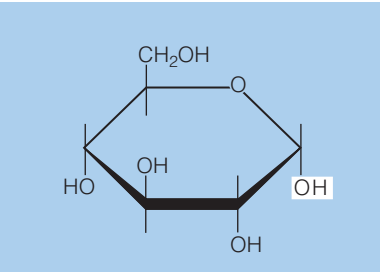
Monosaccharides



Glucose (alpha form). The ring would be at right angles to the plane of the paper. The bonds directed upward are above the plane; those directed downward are below the plane. This molecule is considered an alpha form because the OH on carbon 1 points downward.

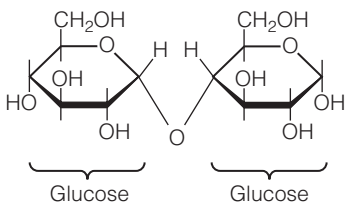


Glucose (beta form). The OH on carbon 1 points upward.
Fructose, galactose: see Chapter 4.

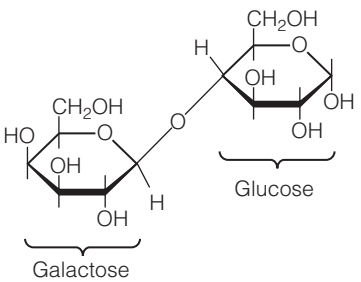


Glucose (alpha form) shorthand notation. This notation, in which the carbons in the ring and single hydrogens have been eliminated, will be used throughout this appendix.

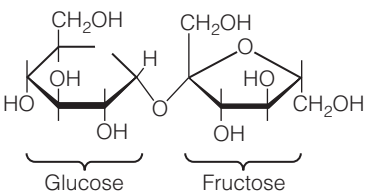
Disaccharides



Maltose.



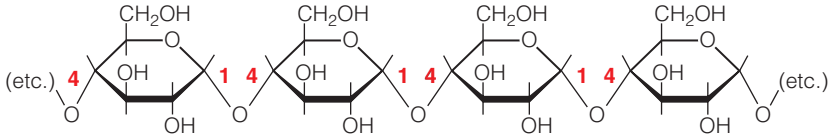
Lactose (alpha form).



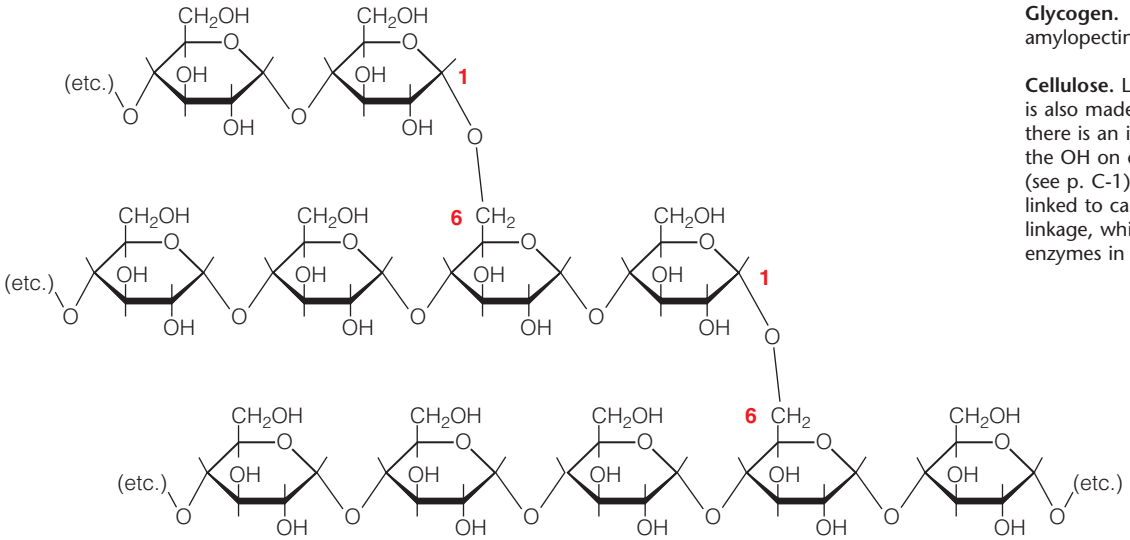
Sucrose.

Polysaccharides

As described in Chapter 4, starch, glycogen, and cellulose are all long chains of glucose molecules covalently linked together.



Amylose (unbranched starch)



Amylopectin (branched starch)

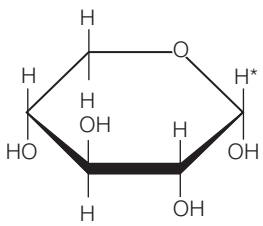
Starch. Two kinds of covalent linkages occur between glucose molecules in starch, giving rise to two kinds of chains. Amylose is composed of straight chains, with carbon 1 of one glucose linked to carbon 4 of the next (α-1,4 linkage). Amylopectin is made up of straight chains like amylose but has occasional branches arising where the carbon 6 of a glucose is also linked to the carbon 1 of another glucose (α-1,6 linkage).

Glycogen. The structure of glycogen is like amylopectin but with many more branches.

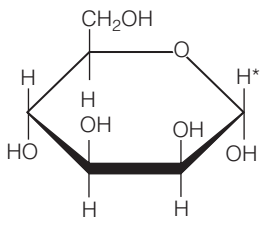
Cellulose. Like starch and glycogen, cellulose is also made of chains of glucose units, but there is an important difference: in cellulose, the OH on carbon 1 is in the beta position (see p. C-1). When carbon 1 of one glucose is linked to carbon 4 of the next, it forms a β-1,4 linkage, which cannot be broken by digestive enzymes in the human GI tract.

Fibers, such as hemicelluloses, consist of long chains of various monosaccharides.

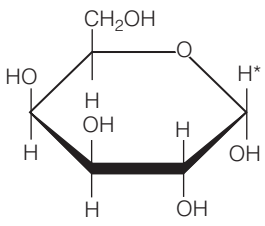
Monosaccharides common in the backbone chain of hemicelluloses:



Xylose



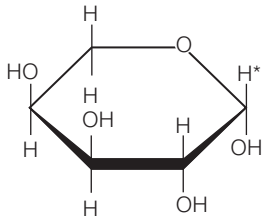
Mannose



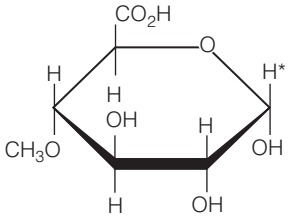
Galactose

*These structures are shown in the alpha form with the H on the carbon pointing upward and the OH pointing downward, but they may also appear in the beta form with the H pointing downward and the OH upward.

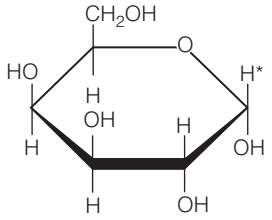
Monosaccharides common in the side chains of hemicelluloses:



Arabinose



Glucuronic acid



Galactose

Hemicelluloses. The most common hemicelluloses are composed of a backbone chain of xylose, mannose, and galactose, with branching side chains of arabinose, glucuronic acid, and galactose.

Lipids

TABLE C-1 Saturated Fatty Acids Found in Natural Fats

Saturated Fatty Acids	Chemical Formulas	Number of Carbons	Major Food Sources
Butyric	C_3H_7COOH	4	Butterfat
Caproic	$C_5H_{11}COOH$	6	Butterfat
Caprylic	$C_7H_{15}COOH$	8	Coconut oil
Capric	$C_9H_{19}COOH$	10	Palm oil
Lauric	$C_{11}H_{23}COOH$	12	Coconut oil, palm oil
Myristic[a]	$C_{13}H_{27}COOH$	14	Coconut oil, palm oil
Palmitic[a]	$C_{15}H_{31}COOH$	16	Palm oil
Stearic[a]	$C_{17}H_{35}COOH$	18	Most animal fats
Arachidic	$C_{19}H_{39}COOH$	20	Peanut oil
Behenic	$C_{21}H_{43}COOH$	22	Seeds
Lignoceric	$C_{23}H_{47}COOH$	24	Peanut oil

[a]Most common saturated fatty acids.

TABLE C-2 Unsaturated Fatty Acids Found in Natural Fats

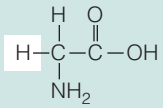
Unsaturated Fatty Acids	Chemical Formulas	Number of Carbons	Number of Double Bonds	Standard Notation[a]	Omega Notation[b]	Major Food Sources
Palmitoleic	$C_{15}H_{29}COOH$	16	1	16:1;9	16:1ω7	Seafood, beef
Oleic	$C_{17}H_{33}COOH$	18	1	18:1;9	18:1ω9	Olive oil, canola oil
Linoleic	$C_{17}H_{31}COOH$	18	2	18:2;9,12	18:2ω6	Sunflower oil, safflower oil
Linolenic	$C_{17}H_{29}COOH$	18	3	18:3;9,12,15	18:3ω3	Soybean oil, canola oil
Arachidonic	$C_{19}H_{31}COOH$	20	4	20:4;5,8,11,14	20:4ω6	Eggs, most animal fats
Eicosapentaenoic	$C_{19}H_{29}COOH$	20	5	20:5;5,8,11,14,17	20:5ω3	Seafood
Docosahexaenoic	$C_{21}H_{31}COOH$	22	6	22:6;4,7,10,13,16,19	22:6ω3	Seafood

NOTE: A fatty acid has two ends; designated the methyl (CH_3) end and the carboxyl, or acid (COOH), end.
[a]Standard chemistry notation begins counting carbons at the acid end. The number of carbons the fatty acid contains comes first, followed by a colon and another number that indicates the number of double bonds; next comes a semicolon followed by a number or numbers indicating the positions of the double bonds. Thus the notation for linoleic acid, an 18-carbon fatty acid with two double bonds between carbons 9 and 10 and between carbons 12 and 13, is 18:2;9,12.
[b]Because fatty acid chains are lengthened by adding carbons at the acid end of the chain, chemists use the omega system of notation to ease the task of identifying them. The omega system begins counting carbons at the methyl end. The number of carbons the fatty acid contains comes first, followed by a colon and the number of double bonds; next come the omega symbol (ω) and a number indicating the position of the double bond nearest the methyl end. Thus linoleic acid with its first double bond at the sixth carbon from the methyl end would be noted 18:2ω6 in the omega system.

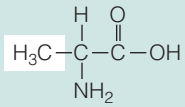
Protein: Amino Acids

The common amino acids may be classified into the seven groups listed on the next page. Amino acids marked with an asterisk (*) are essential.

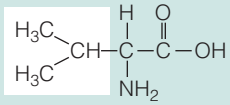
1. Amino acids with aliphatic side chains, which consist of hydrogen and carbon atoms (hydrocarbons):



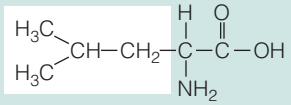
Glycine (Gly)



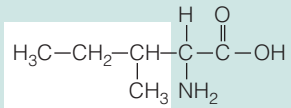
Alanine (Ala)



Valine* (Val)

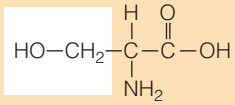


Leucine* (Leu)

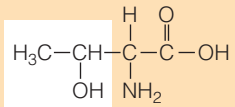


Isoleucine* (Ile)

2. Amino acids with hydroxyl (OH) side chains:

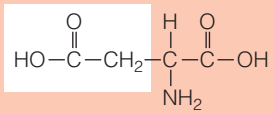


Serine (Ser)

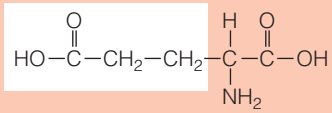


Threonine* (Thr)

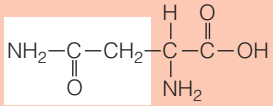
3. Amino acids with side chains containing acidic groups or their amides, which contain the group NH_2:



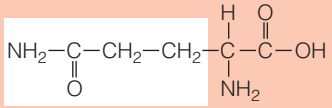
Aspartic acid (Asp)



Glutamic acid (Glu)

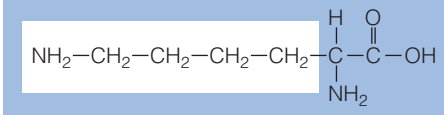


Asparagine (Asn)

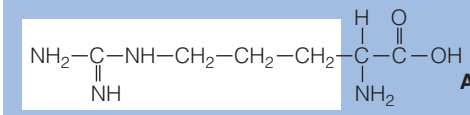


Glutamine (Gln)

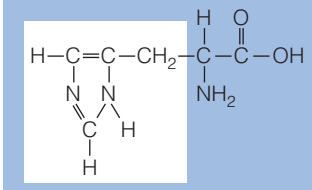
4. Amino acids with basic side chains:



Lysine* (Lys)

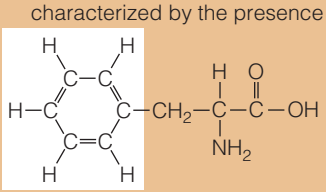


Arginine (Arg)

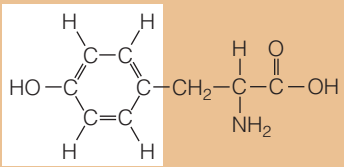


Histidine* (His)

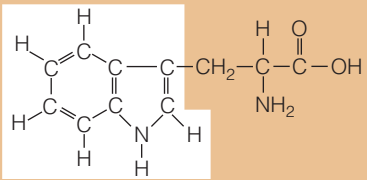
5. Amino acids with aromatic side chains, which are characterized by the presence of at least one ring structure:



Phenylalanine* (Phe)

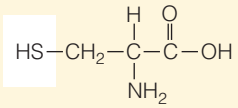


Tyrosine (Tyr)

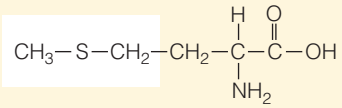


Tryptophan* (Trp)

6. Amino acids with side chains containing sulfur atoms:

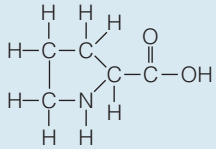


Cysteine (Cys)



Methionine* (Met)

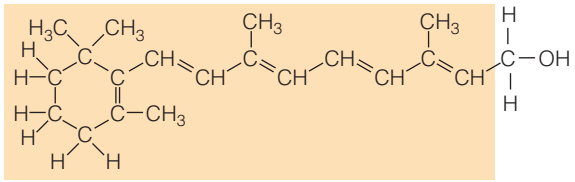
7. Imino acid:



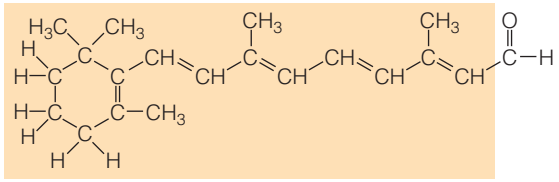
Proline (Pro)

Proline has the same chemical structure as the other amino acids, but its amino group has given up a hydrogen to form a ring.

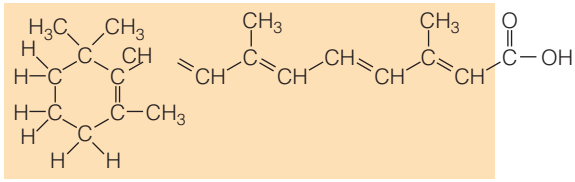
Vitamins and Coenzymes



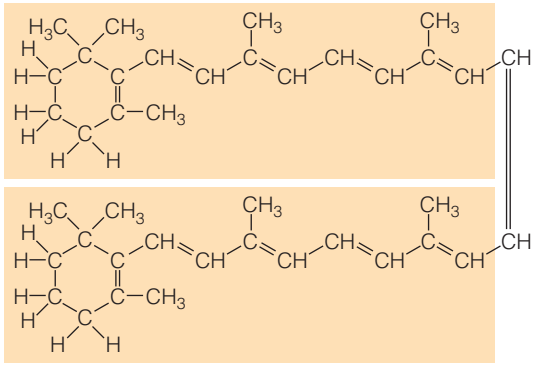
Vitamin A: retinol. This molecule is the alcohol form of vitamin A.



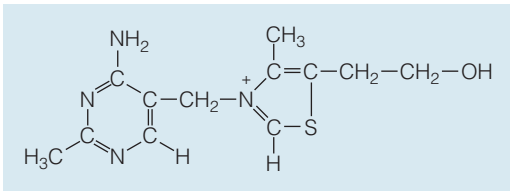
Vitamin A: retinal. This molecule is the aldehyde form of vitamin A.



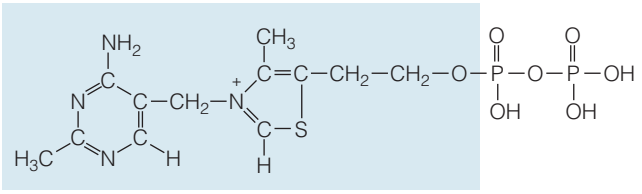
Vitamin A: retinoic acid. This molecule is the acid form of vitamin A.



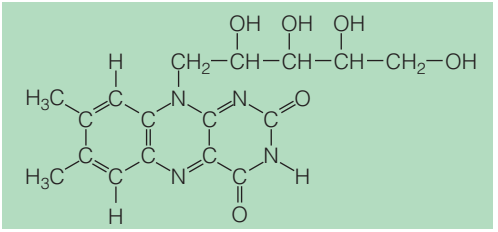
Vitamin A precursor: beta-carotene. This molecule is the carotenoid with the most vitamin A activity.



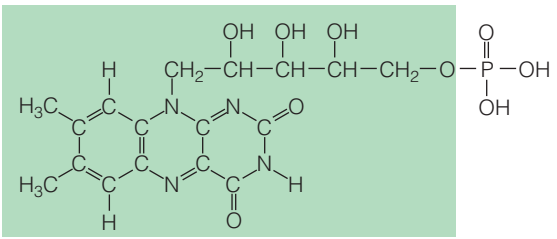
Thiamin. This molecule is part of the coenzyme thiamin pyrophosphate (TPP).



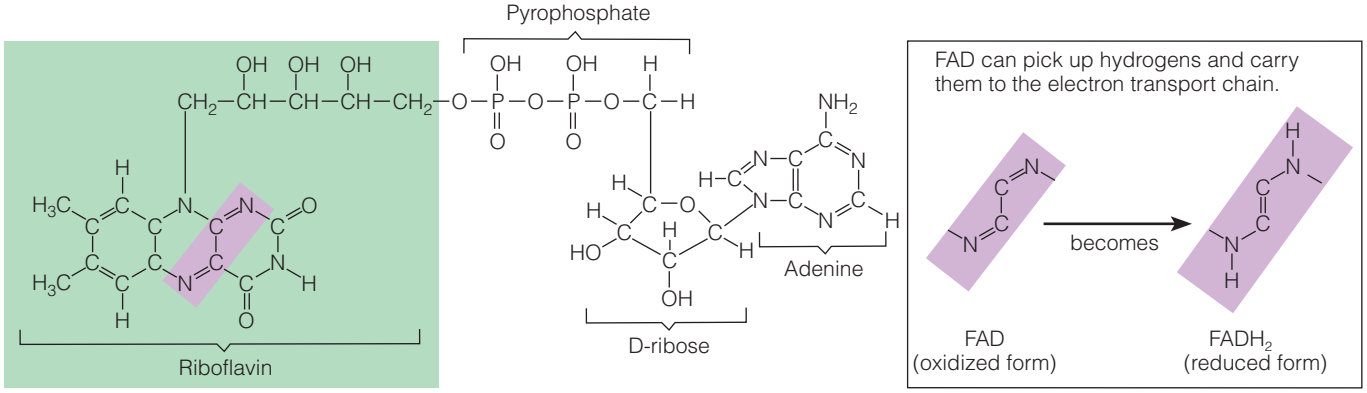
Thiamin pyrophosphate (TPP). TPP is a coenzyme that includes the thiamin molecule as part of its structure.



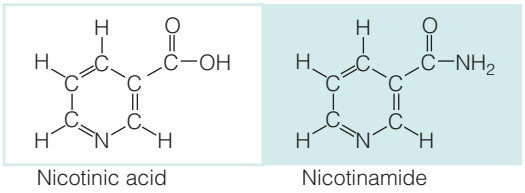
Riboflavin. This molecule is a part of two coenzymes—flavin mononucleotide (FMN) and flavin adenine dinucleotide (FAD).



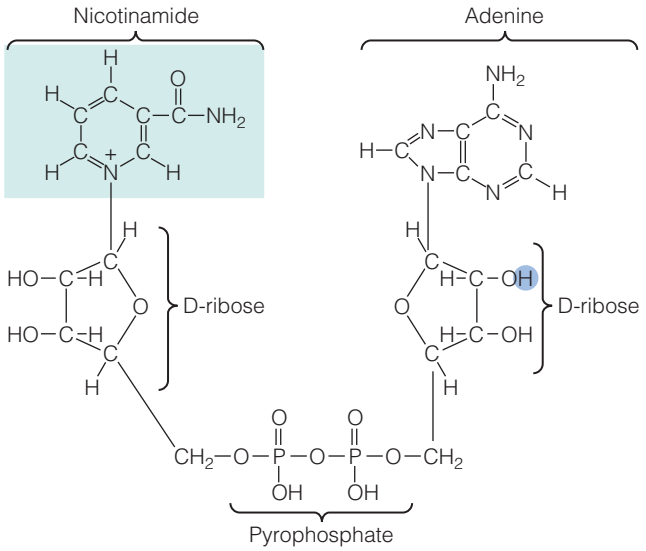
Flavin mononucleotide (FMN). FMN is a coenzyme that includes the riboflavin molecule as part of its structure.



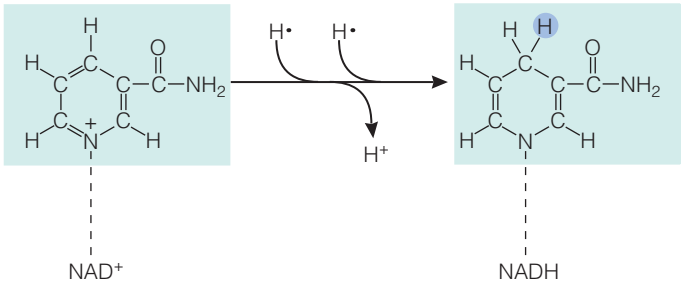
Flavin adenine dinucleotide (FAD). FAD is a coenzyme that includes the riboflavin molecule as part of its structure.



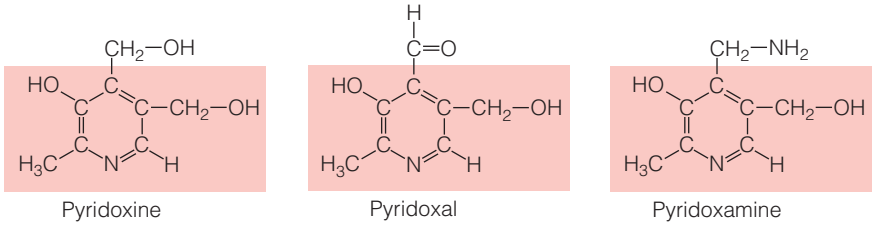
Niacin (nicotinic acid and nicotinamide). These molecules are a part of two coenzymes—nicotinamide adenine dinucleotide (NAD^+) and nicotinamide adenine dinucleotide phosphate ($NADP^+$).



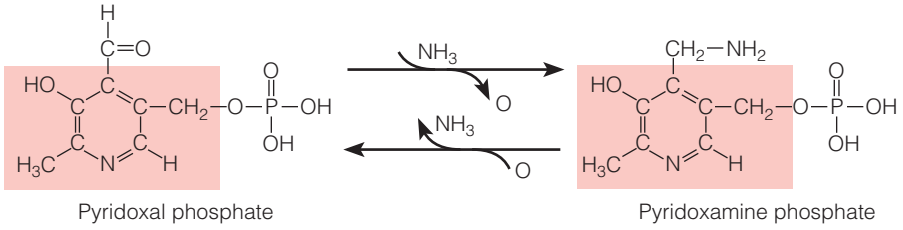
Nicotinamide adenine dinucleotide (NAD^+) and nicotinamide adenine dinucleotide phosphate ($NADP^+$). NADP has the same structure as NAD but with a phosphate group attached to the O instead of the H.



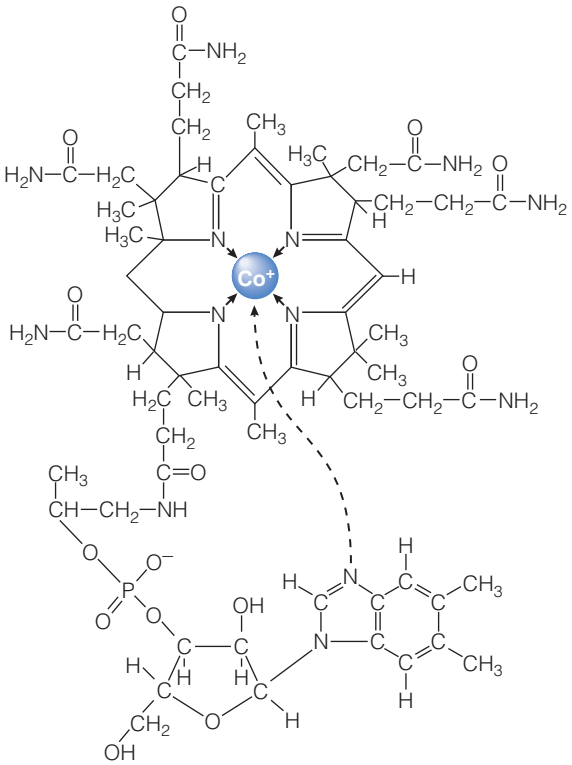
Reduced NAD^+ ($NADH$). When NAD^+ is reduced by the addition of H^+ and two electrons, it becomes the coenzyme NADH. (The dots on the H entering this reaction represent electrons—see Appendix B.)



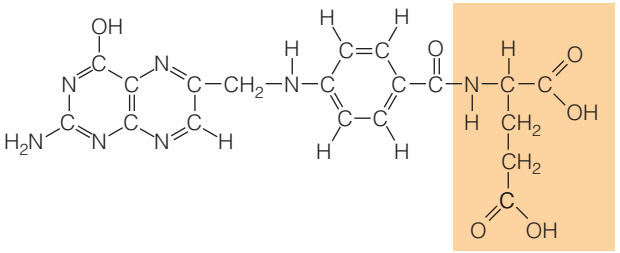
Vitamin B_6 (a general name for three compounds—pyridoxine, pyridoxal, and pyridoxamine). These molecules are a part of two coenzymes—pyridoxal phosphate and pyridoxamine phosphate.



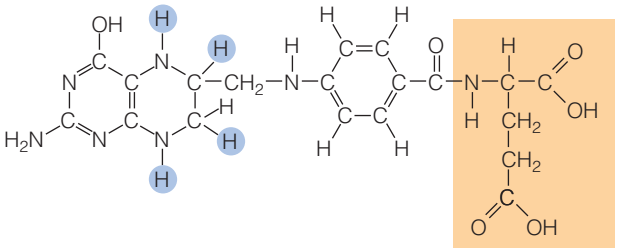
Pyridoxal phosphate (PLP) and pyridoxamine phosphate. These coenzymes include vitamin B_6 as part of their structures.



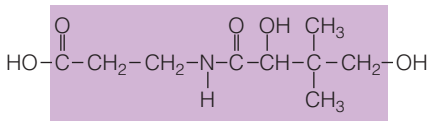
Vitamin B_{12} (cyanocobalamin). The arrows in this diagram indicate that the spare electron pairs on the nitrogens attract them to the cobalt.



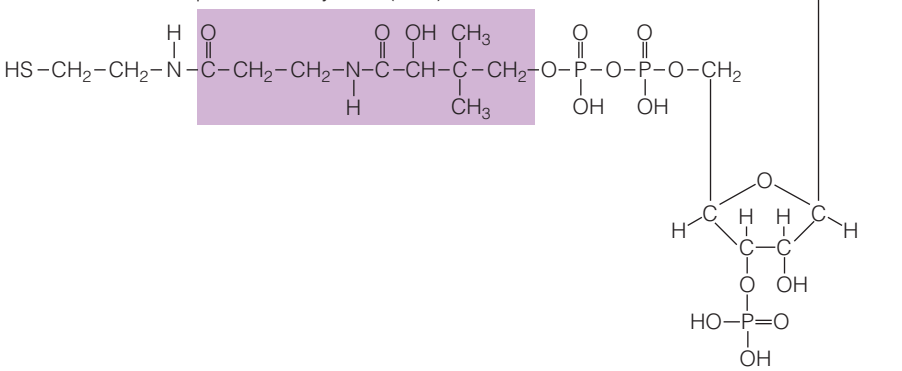
Folate (folacin or folic acid). This molecule consists of a double ring combined with a single ring and at least one glutamate (a nonessential amino acid marked in the box). Folate's biologically active form is tetrahydrofolate.



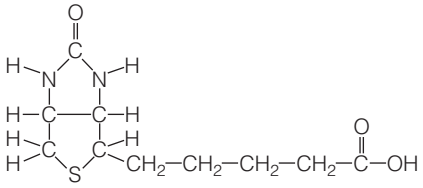
Tetrahydrofolate. This active coenzyme form of folate has four added hydrogens. An intermediate form, dihydrofolate, has two added hydrogens.



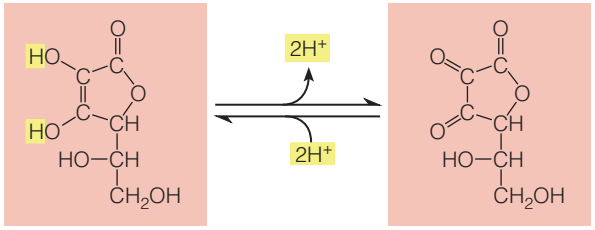
Pantothenic acid. This molecule is part of coenzyme A (CoA).



Coenzyme A (CoA). Coenzyme A is a coenzyme that includes pantothenic acid as part of its structure.



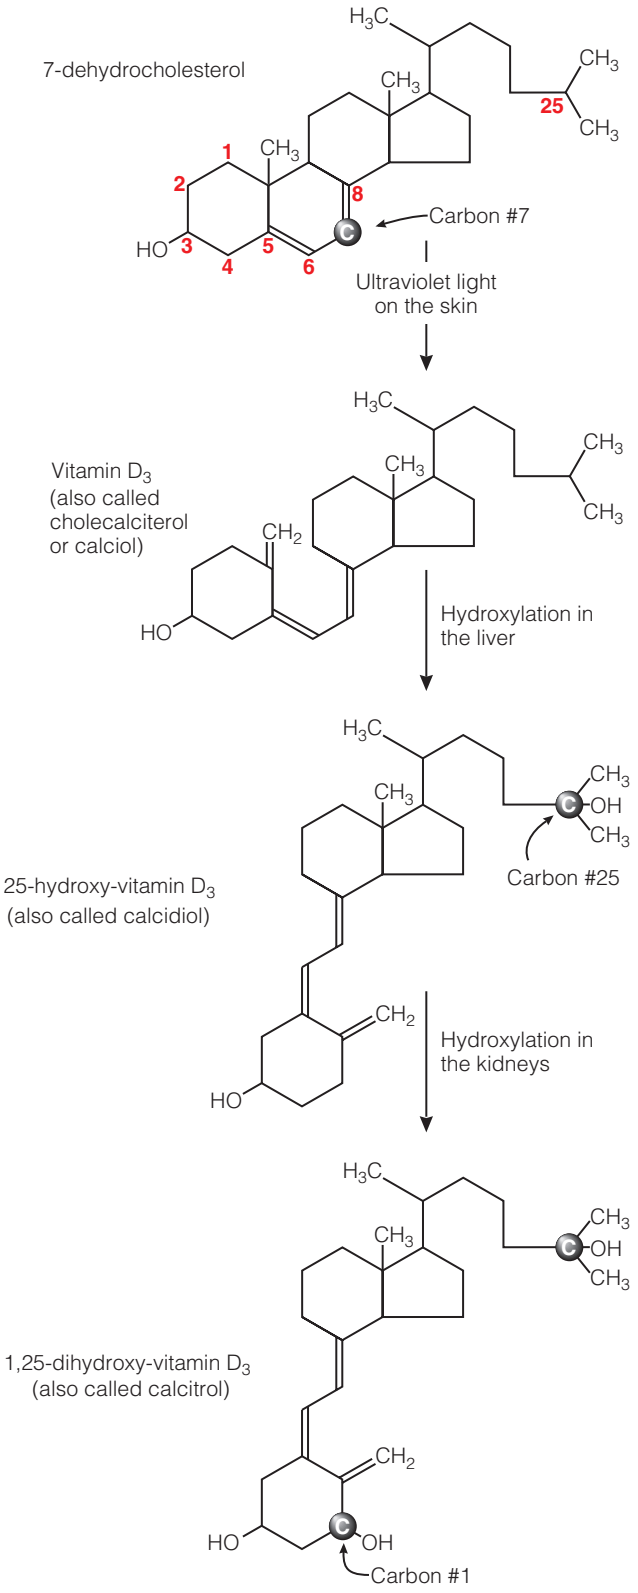
Biotin.



Ascorbic acid
(reduced form)

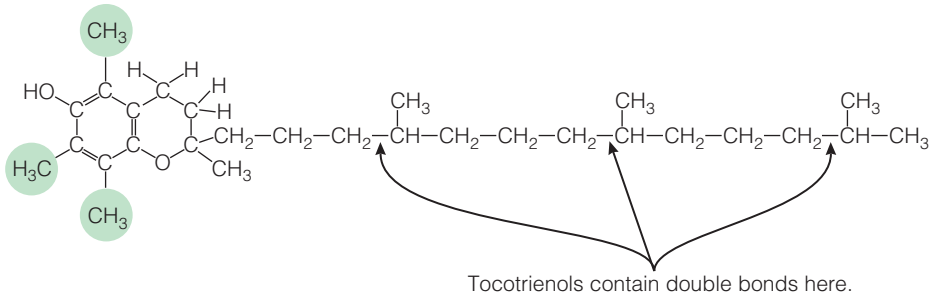
Dehydroascorbic acid
(oxidized form)

Vitamin C. Two hydrogen atoms with their electrons are lost when ascorbic acid is oxidized and gained when it is reduced again.

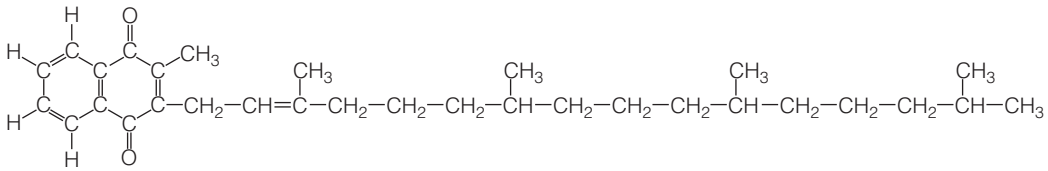


Vitamin D. The synthesis of active vitamin D begins with 7-dehydrocholesterol. (The carbon atoms at which changes occur are numbered.)

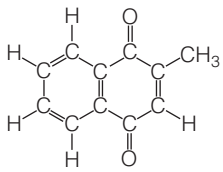
Appendix C



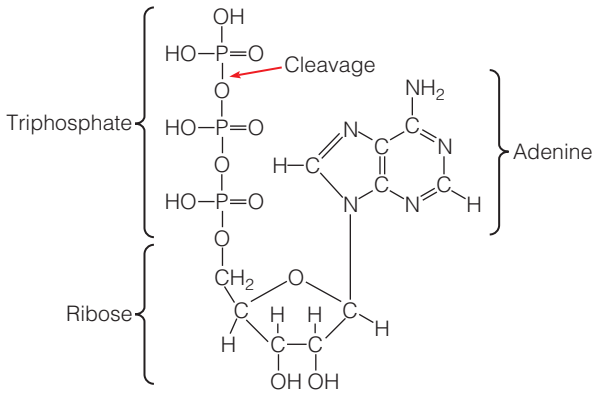
Vitamin E (alpha-tocopherol). The number and position of the methyl groups (CH_3) bonded to the ring structure differentiate among the tocopherols.



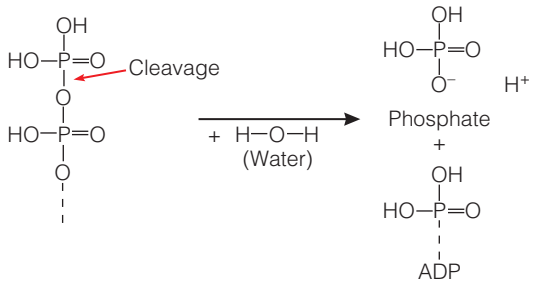
Vitamin K. Naturally occurring compounds with vitamin K activity include phylloquinones (from plants) and menaquinones (from bacteria).



Menadione. This synthetic compound has the same activity as natural vitamin K.



Adenosine triphosphate (ATP), the energy carrier. The cleavage point marks the bond that is broken when ATP splits to become ADP + P.



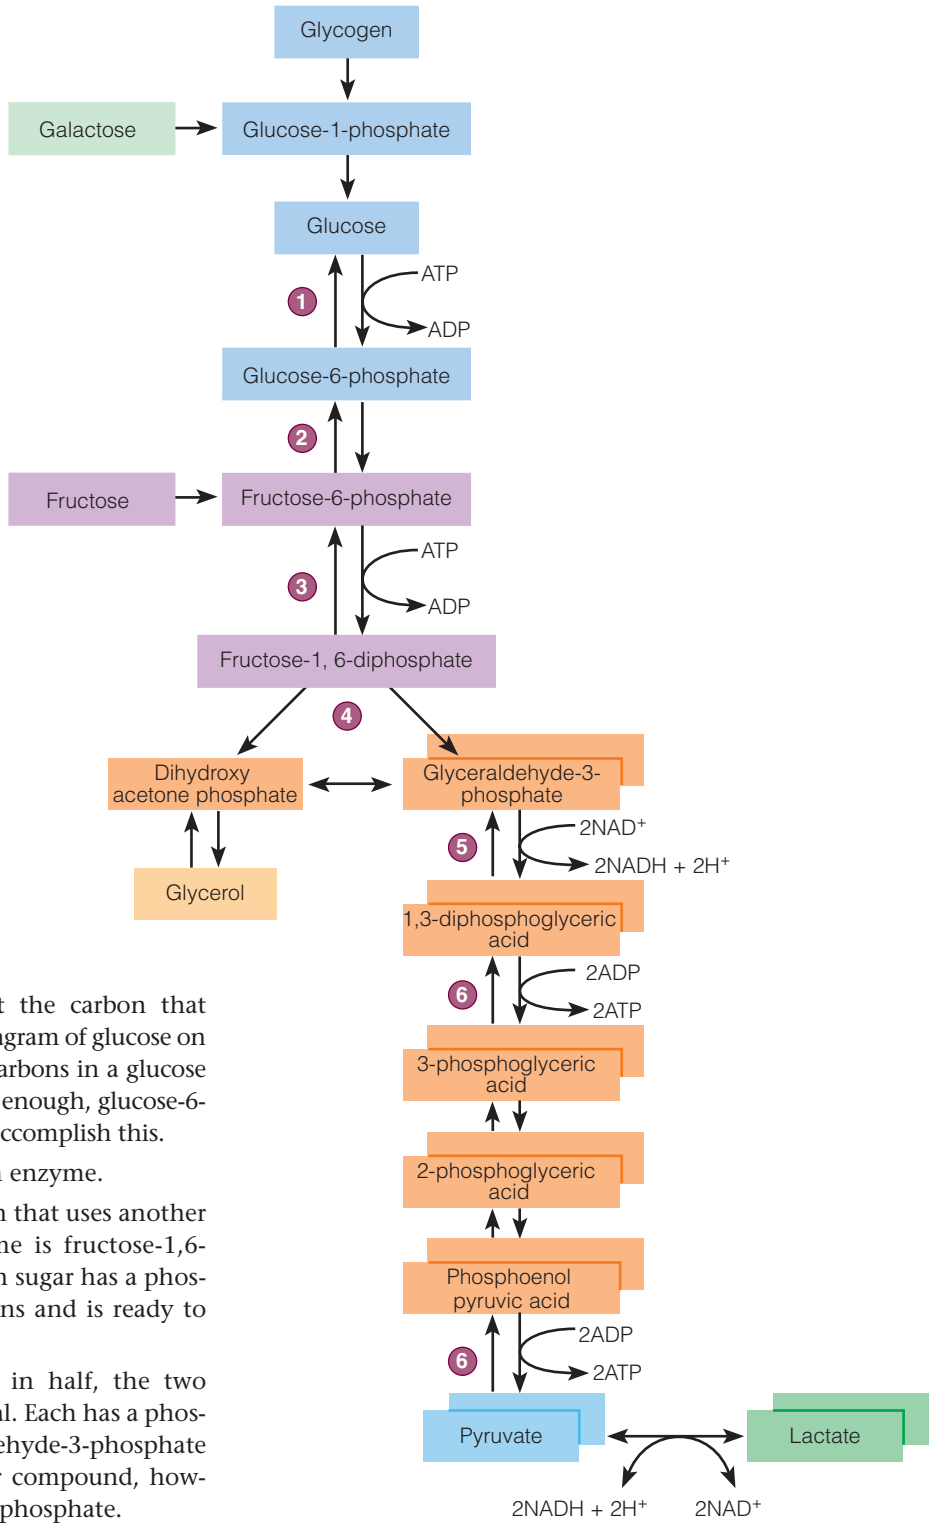
Adenosine diphosphate (ADP).

Glycolysis

Figure C-1 depicts the events of glycolysis. The following text describes key steps as numbered on the figure.

FIGURE C-1 Glycolysis

Notice that galactose and fructose enter at different places but continue on the same pathway.



1. A phosphate is attached to glucose at the carbon that chemists call number 6 (review the first diagram of glucose on p. C-1 to see how chemists number the carbons in a glucose molecule). The product is called, logically enough, glucose-6-phosphate. One ATP molecule is used to accomplish this.
2. Glucose-6-phosphate is rearranged by an enzyme.
3. A phosphate is added in another reaction that uses another molecule of ATP. The product this time is fructose-1,6-diphosphate. At this point the six-carbon sugar has a phosphate group on its first and sixth carbons and is ready to break apart.
4. When fructose-1,6-diphosphate breaks in half, the two three-carbon compounds are not identical. Each has a phosphate group attached, but only glyceraldehyde-3-phosphate converts directly to pyruvate. The other compound, however, converts easily to glyceraldehyde-3-phosphate.

5. In the next step, enough energy is released to convert NAD^+ to NADH + H^+.
6. In two of the following steps ATP is regenerated.

Remember that in effect two molecules of glyceraldehyde-3-phosphate are produced from glucose; therefore, four ATP molecules are generated from each glucose molecule. Two ATP were needed to get the sequence started, so the net gain at this point is two ATP and two molecules of NADH + H^+. As you will see later, each NADH + H^+ moves to the electron transport chain to unload its hydrogens onto oxygen, producing more ATP.

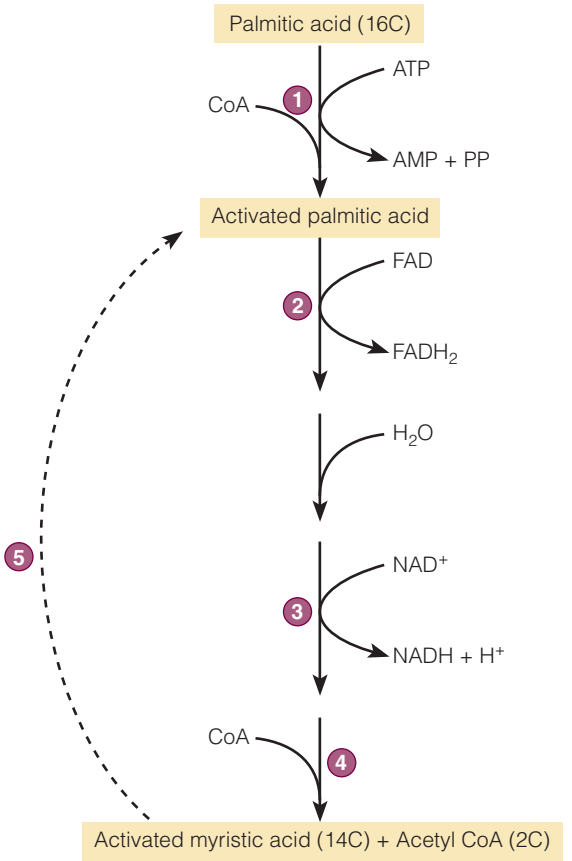
Fatty Acid Oxidation

Figure C-2 presents fatty acid oxidation. The sequence is as follows.

1. The fatty acid is activated by combining with coenzyme A (CoA). In this reaction, ATP loses two phosphorus atoms (PP, or pyrophosphate) and becomes AMP (adenosine monophosphate)—the equivalent of a loss of two ATP.
2. In the next reaction, two H with their electrons are removed and transferred to FAD, forming $FADH_2$.
3. In a later reaction, two H are removed and go to NAD^+ (forming NADH + H^+).
4. The fatty acid is cleaved at the "beta" carbon, the second carbon from the carboxyl (COOH) end. This break results in a fatty acid that is two carbons shorter than the previous one and a two-carbon molecule of acetyl CoA. At the same time, another CoA is attached to the fatty acid, thus activating it for its turn through the series of reactions.
5. The sequence is repeated with each cycle producing an acetyl CoA and a shorter fatty acid until only a 2-carbon fatty acid remains—acetyl CoA.

In the example shown in Figure C-2, palmitic acid (a 16-carbon fatty acid) will go through this series of reactions seven times, using the equivalent of two ATP for the initial activation and generating seven $FADH_2$, seven NADH + H^+, and eight acetyl CoA. As you will see later, each of the seven $FADH_2$ will enter the electron transport chain to unload its hydrogens onto oxygen, yielding two ATP (for a total of 14). Similarly, each NADH + H^+ will enter the electron transport chain to unload its hydrogens onto oxygen, yielding three ATP (for a total of 21). Thus the oxidation of a 16-carbon fatty acid uses 2 ATP and generates 35 ATP. When the eight acetyl CoA enter the TCA cycle, even more ATP will be generated, as a later section describes.

FIGURE C-2 Fatty Acid Oxidation

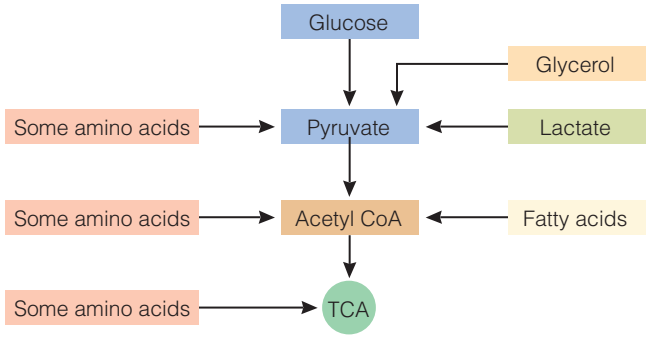


Amino Acid Degradation

The first step in amino acid degradation is the removal of the nitrogen-containing amino group through either deamination (Figure 7-14 on p. 226) or transamination (Figure 7-15 on p. 226) reactions. Then the remaining carbon skeletons may enter the metabolic pathways at different places, as shown in Figure C-3.

The TCA Cycle

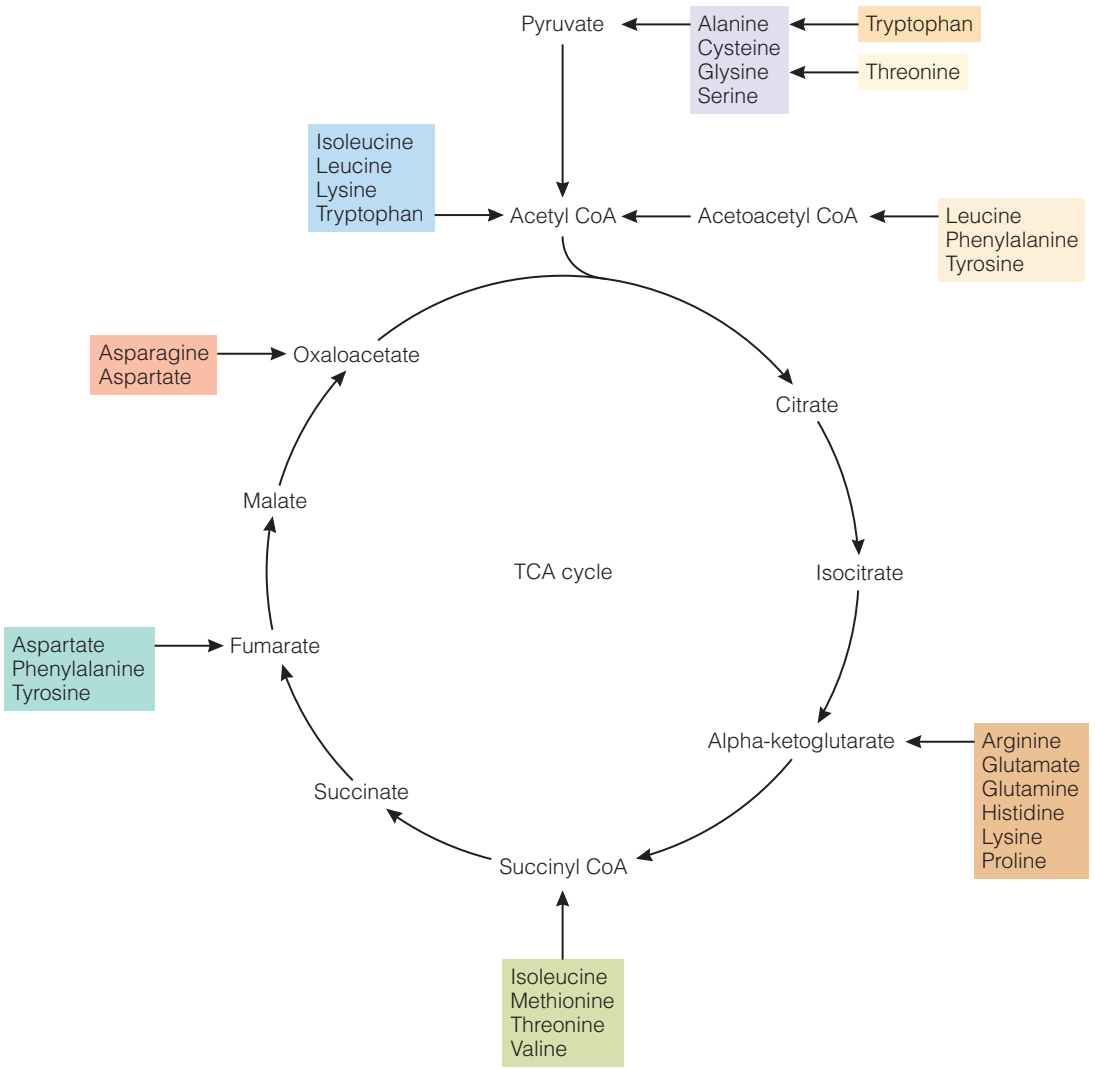
The tricarboxylic acid, or TCA, cycle is the set of reactions that break down acetyl CoA to carbon dioxide and hydrogens. To link glycolysis to the TCA cycle, pyruvate enters the mitochondrion, loses a carbon group, and bonds with a molecule of CoA to become acetyl CoA. The TCA cycle uses any substance that can be converted to acetyl CoA directly or indirectly through pyruvate.

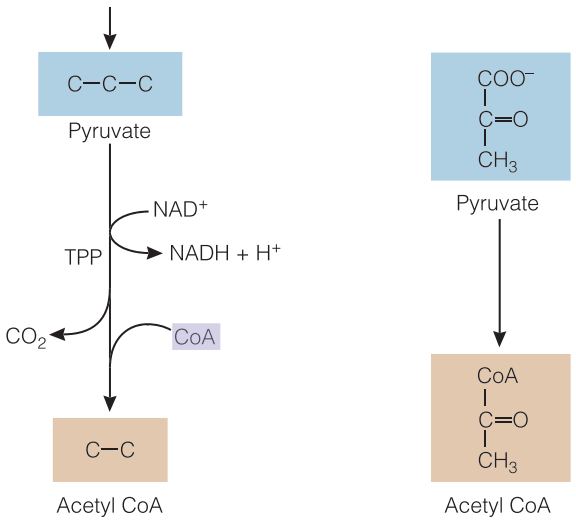


The step from pyruvate to acetyl CoA is complex. We have included only those substances that will help you understand

FIGURE C-3 Amino Acid Degradation

After losing their amino groups, carbon skeletons can be converted to one of seven molecules that can enter the TCA cycle (presented in Figure C-4).





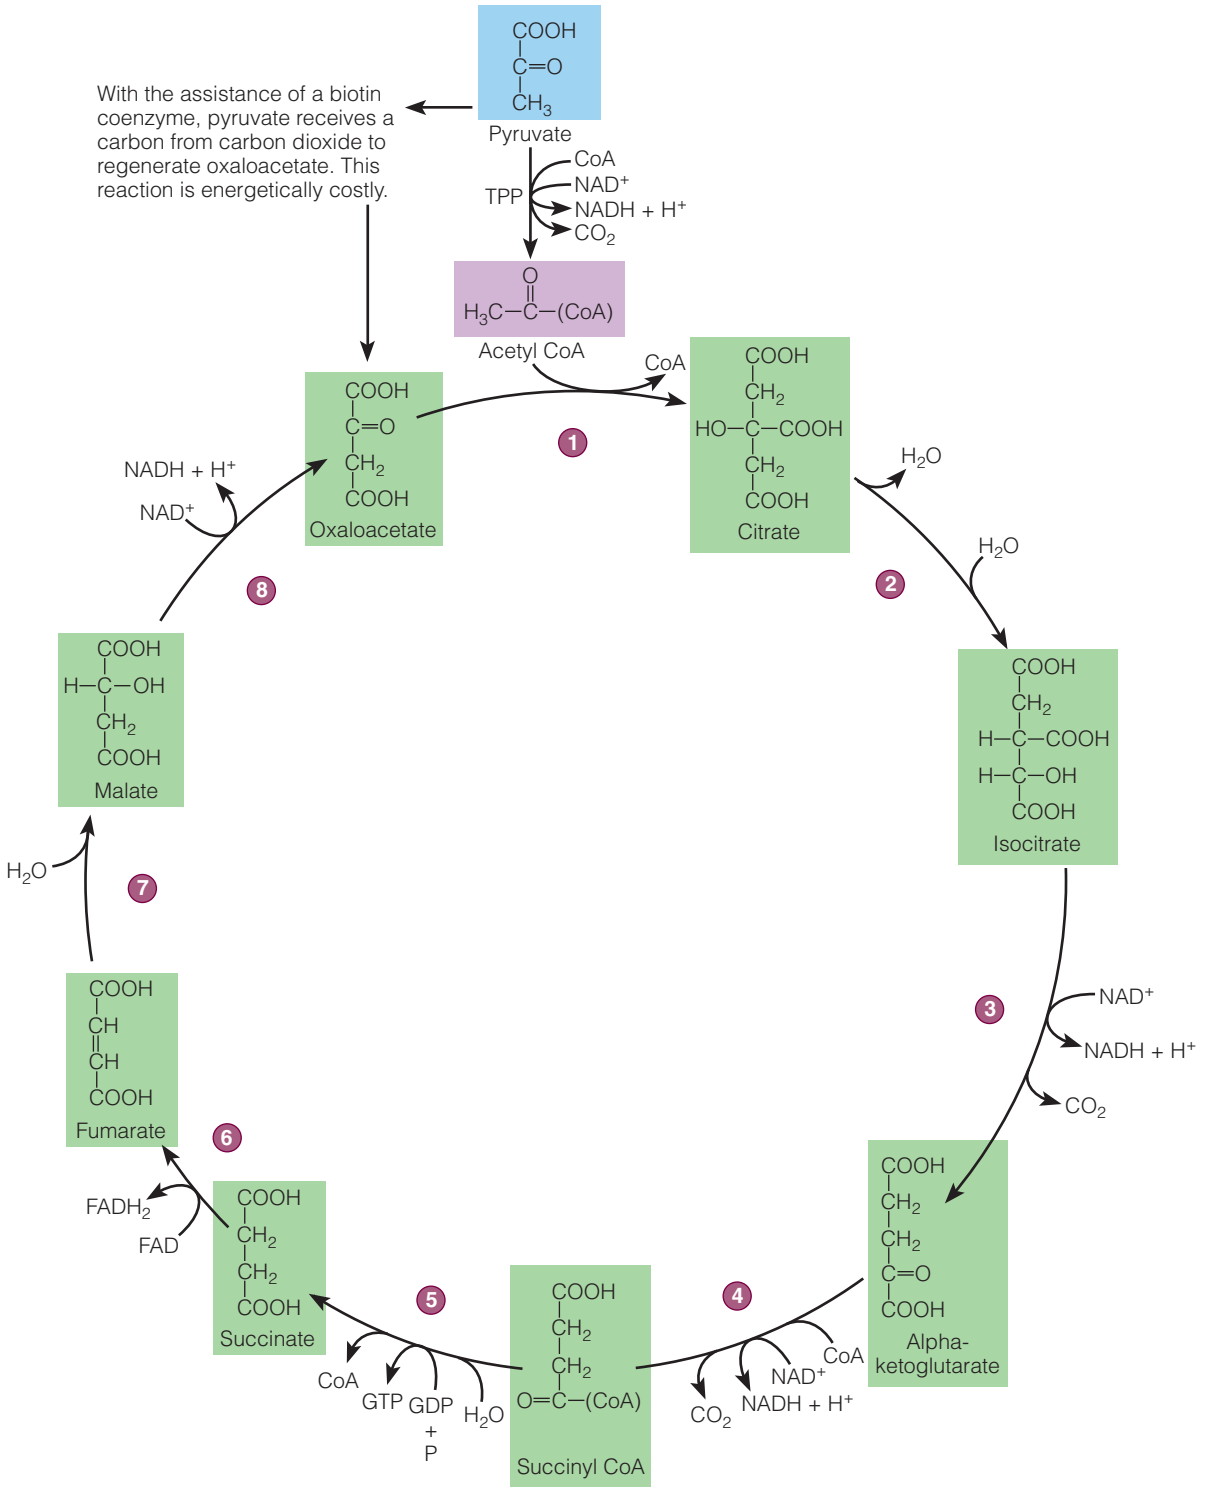
The step from pyruvate to acetyl CoA. (TPP and NAD are coenzymes containing the B vitamins thiamin and niacin, respectively.)

the transfer of energy from the nutrients. Pyruvate loses a carbon to carbon dioxide and is attached to a molecule of CoA. In the process, NAD^+ picks up two hydrogens with their associated electrons, becoming $NADH + H^+$.

Let's follow the steps of the TCA cycle (see the corresponding numbers in Figure C-4).

1. The two-carbon acetyl CoA combines with a four-carbon compound, oxaloacetate. The CoA comes off, and the product is a six-carbon compound, citrate.
2. The atoms of citrate are rearranged to form isocitrate.
3. Now two H (with their two electrons) are removed from the isocitrate. One H becomes attached to the NAD^+ with the two electrons; the other H is released as H^+. Thus NAD^+ becomes $NADH + H^+$. (Remember this $NADH + H^+$, but let's follow the carbons first.) A carbon is combined with two oxygens, forming carbon dioxide (which diffuses away into the blood and is exhaled). What is left is the five-carbon compound alpha-ketoglutarate.

FIGURE C-4 The TCA Cycle



4. Now two compounds interact with alpha-ketoglutarate —a molecule of CoA and a molecule of NAD^+. In this complex reaction, a carbon and two oxygens are removed (forming carbon dioxide); two hydrogens are removed and go to NAD^+ (forming NADH + H^+); and the remaining four-carbon compound is attached to the CoA, forming succinyl CoA. (Remember this NADH + H^+ also. You will see later what happens to it.)
5. Now two molecules react with succinyl CoA—a molecule called GDP and one of phosphate (P). The CoA comes off, the GDP and P combine to form the high-energy compound GTP (similar to ATP), and succinate remains. (Remember this GTP.)

6. In the next reaction, two H with their electrons are removed from succinate and are transferred to a molecule of FAD (a coenzyme like NAD^+) to form $FADH_2$. The product that remains is fumarate. (Remember this $FADH_2$.)
7. Next a molecule of water is added to fumarate, forming malate.
8. A molecule of NAD^+ reacts with the malate; two H with their associated electrons are removed from the malate and form NADH + H^+. The product that remains is the four-carbon compound oxaloacetate. (Remember this NADH + H^+.)

We are back where we started. The oxaloacetate formed in this process can combine with another molecule of acetyl CoA (step 1), and the cycle can begin again, as shown in Figure C-4.

So far, we have seen two carbons brought in with acetyl CoA and two carbons ending up in carbon dioxide. But where are the energy and the ATP we promised?

A review of the eight steps of the TCA cycle shows that the compounds NADH + H^+ (three molecules), $FADH_2$, and GTP capture energy originally found in acetyl CoA. To see how this energy ends up in ATP, we must follow the electrons further—into the electron transport chain.

The Electron Transport Chain

The six reactions described here are those of the electron transport chain, which is shown in Figure C-5. Since oxygen is required for these reactions, and ADP and P are combined to form ATP in several of them (ADP is phosphorylated), these reactions are also called oxidative phosphorylation.

An important concept to remember at this point is that an electron is not a fixed amount of energy. The electrons that bond the H to NAD^+ in NADH have a relatively large amount of energy. In the series of reactions that follow, they release this energy in small amounts, until at the end they are attached (with H) to oxygen (O) to make water (H_2O). In some of the steps, the energy they release is captured into ATP in coupled reactions.

1. In the first step of the electron transport chain, NADH reacts with a molecule called a flavoprotein, losing its electrons (and their H). The products are NAD^+ and reduced flavoprotein. A little energy is released as heat in this reaction.
2. The flavoprotein passes on the electrons to a molecule called coenzyme Q. Again they release some energy as heat, but ADP and P bond together and form ATP, storing much of the energy. This is a coupled reaction: ADP + P → ATP.
3. Coenzyme Q passes the electrons to cytochrome *b*. Again the electrons release energy.
4. Cytochrome *b* passes the electrons to cytochrome *c* in a coupled reaction in which ATP is formed: ADP + P → ATP.
5. Cytochrome *c* passes the electrons to cytochrome *a*.
6. Cytochrome *a* passes them (with their H) to an atom of oxygen (O), forming water (H_2O). This is a coupled reaction in which ATP is formed: ADP + P → ATP.

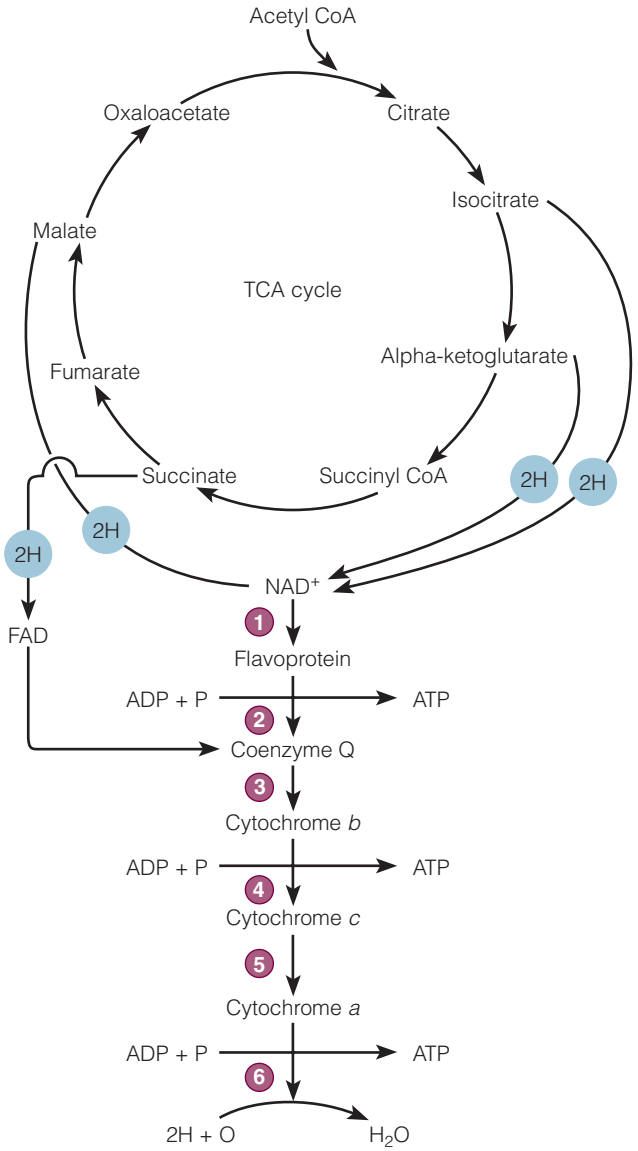
As Figure C-5 shows, each time NADH is oxidized (loses its electrons) by this means, the energy it releases is captured into three ATP molecules. When the electrons are passed on to water at the end, they are much lower in energy than they were originally. This completes the story of the electrons from NADH.

As for $FADH_2$, its electrons enter the electron transport chain at coenzyme Q. From coenzyme Q to water, ATP is generated in only two steps. Therefore, $FADH_2$ coming out of the TCA cycle yields just two ATP molecules.

One energy-receiving compound of the TCA cycle (GTP) does not enter the electron transport chain but gives its energy directly to ADP in a simple phosphorylation reaction. This reaction yields one ATP.

It is now possible to draw up a balance sheet of glucose metabolism (see Table C-3). Glycolysis has yielded 4 NADH + H^+ and 4 ATP molecules and has spent 2 ATP. The 2 acetyl CoA

FIGURE C-5 The Electron Transport Chain



going through the TCA cycle have yielded 6 NADH + H^+, 2 $FADH_2$, and 2 GTP molecules. After the NADH + H^+ and $FADH_2$ have gone through the electron transport chain, there are 28 ATP. Added to these are the 4 ATP from glycolysis and the 2 ATP from GTP, making the total 34 ATP generated from one molecule of glucose. After the expense of 2 ATP is subtracted, there is a net gain of 32 ATP.*

A similar balance sheet from the complete breakdown of one 16-carbon fatty acid would show a net gain of 129 ATP. As mentioned earlier, 35 ATP were generated from the seven $FADH_2$ and seven NADH + H^+ produced during fatty acid oxidation. The eight acetyl CoA produced will each generate 12 ATP as they go through the TCA cycle and the electron transport chain, for a total of 96 more ATP. After subtracting the 2 ATP needed to activate the fatty acid initially, the net yield from one 16-carbon fatty acid: 35 + 96 − 2 = 129 ATP.

These calculations help explain why fat yields more energy (measured as kcalories) per gram than carbohydrate or protein. The more hydrogen atoms a fuel contains, the more ATP will be generated during oxidation. The 16-carbon fatty acid molecule, with its 32 hydrogen atoms, generates 129 ATP, whereas glucose, with its 12 hydrogen atoms, yields only 32 ATP.

The TCA cycle and the electron transport chain are the body's major means of capturing the energy from nutrients in ATP molecules. Other means, such as anaerobic glycolysis, contribute energy quickly, but the aerobic processes are the most efficient. Biologists and chemists understand much more about these processes than has been presented here.

TABLE C-3 Balance Sheet for Glucose Metabolism

		ATP
Glycolysis:	4 ATP − 2 ATP	2
1 glucose to 2 pyruvate	2 NADH + H^+	3-5[a]
2 pyruvate to 2 acetyl CoA	2 NADH + H^+	5
TCA cycle and electron transport chain:		
2 isocitrate	2 NADH + H^+	5
2 alpha-ketoglutarate	2 NADH + H^+	5
2 succinyl CoA	2 GTP	2
2 succinate	2 $FADH_2$	3
2 malate	2 NADH + H^+	5
Total ATP collected from one molecule glucose:		30–32

[a]Each NADH + H^+ from glycolysis can yield 1.5 or 2.5 ATP. See the accompanying text.

Alcohol's Interference with Energy Metabolism

Highlight 7 provides an overview of how alcohol interferes with energy metabolism. With an understanding of the TCA cycle, a few more details may be appreciated. During alcohol metabolism, the enzyme alcohol dehydrogenase oxidizes alcohol to acetaldehyde while it simultaneously reduces a molecule of NAD^+ to NADH + H^+. The related enzyme acetaldehyde dehydrogenase reduces another NAD^+ to NADH + H^+ while it oxidizes acetaldehyde to acetyl CoA, the compound that enters the TCA cycle to generate energy. Thus, whenever alcohol is being metabolized in the body, NAD^+ diminishes, and NADH + H^+ accumulates. Chemists say that the body's "redox state" is altered, because NAD^+ can oxidize, and NADH + H^+ can reduce, many other body compounds. During alcohol metabolism, NAD^+ becomes unavailable for the multitude of reactions for which it is required.

As the previous sections just explained, for glucose to be completely metabolized, the TCA cycle must be operating, and NAD^+ must be present. If these conditions are not met (and when alcohol is present, they may not be), the pathway will be blocked, and traffic will back up—or an alternate route will be taken. Think about this as you follow the pathway shown in Figure C-6.

In each step of alcohol metabolism in which NAD^+ is converted to NADH + H^+, hydrogen ions accumulate, resulting in a dangerous shift of the acid-base balance toward acid (Chapter 12 explains acid-base balance). The accumulation of NADH + H^+ slows TCA cycle activity, so pyruvate and acetyl CoA build up. This condition favors the conversion of pyruvate to lactate, which serves as a temporary storage place for hydrogens from NADH + H^+. The conversion of pyruvate to lactate restores some NAD^+, but a lactate buildup has serious consequences of its own. It adds to the body's acid burden and interferes with the excretion of uric acid, causing goutlike symptoms. Molecules of acetyl CoA become building blocks for fatty acids or ketone bodies. The making of ketone bodies consumes acetyl CoA and generates NAD^+; but some ketone bodies are acids, so they push the acid-base balance further toward acid.

Thus alcohol cascades through the metabolic pathways, wreaking havoc along the way. These consequences have physical effects, which Highlight 7 describes.

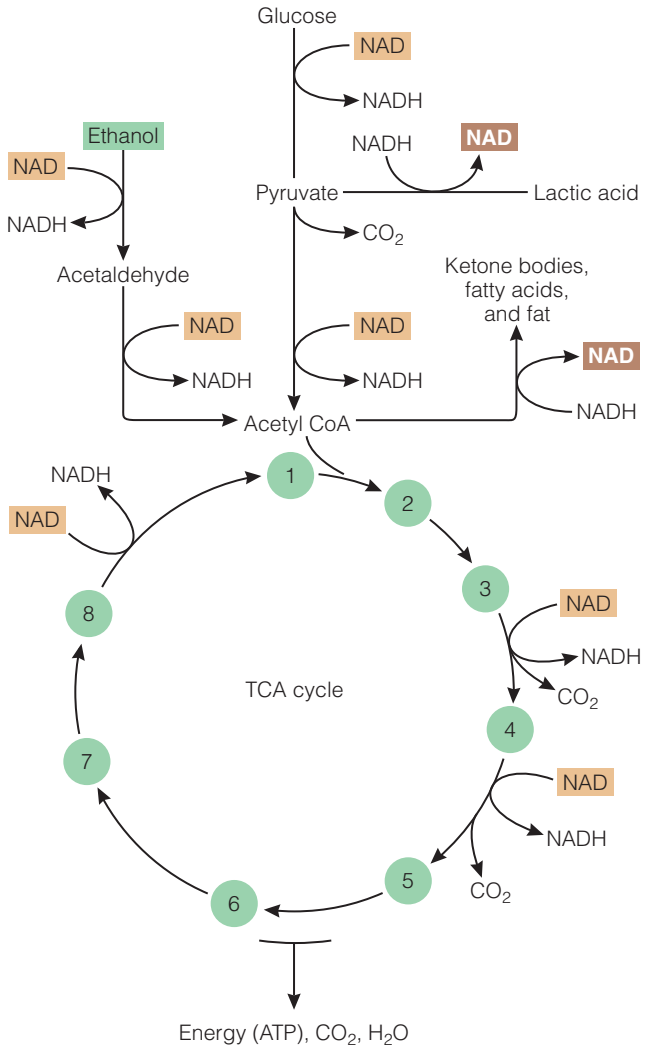
The Urea Cycle

Chapter 7 sums up the process by which waste nitrogen is eliminated from the body by stating that ammonia molecules combine with carbon dioxide to produce urea. This is true, but it is not the whole story. Urea is produced in a multistep process within the cells of the liver.

*The total may sometimes be 30 ATP. The NADH + H^+ generated in the cytoplasm during glycolysis pass their electrons on to shuttle molecules, which move them into the mitochondria. One shuttle, malate, contributes its electrons to the electron transport chain before the first site of ATP synthesis, yielding 5 ATP. Another, glycerol phosphate, adds its electrons into the chain beyond that first site, yielding 3 ATP. Thus sometimes 5, and sometimes 3, ATP result from the NADH + H^+ that arise from glycolysis. The amount depends on the cell.

FIGURE C-6 Ethanol Enters the Metabolic Path

This is a simplified version of the glucose-to-energy pathway showing the entry of ethanol. The coenzyme NAD (which is the active form of the B vitamin niacin) is the only one shown here; however, many others are involved.



Ammonia, freed from an amino acid or other compound during metabolism anywhere in the body, arrives at the liver by way of the bloodstream and is taken into a liver cell. There, it is first combined with carbon dioxide and a phosphate group from ATP to form carbamyl phosphate:

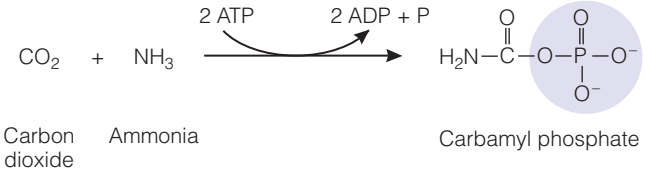


FIGURE C-7 The Urea Cycle

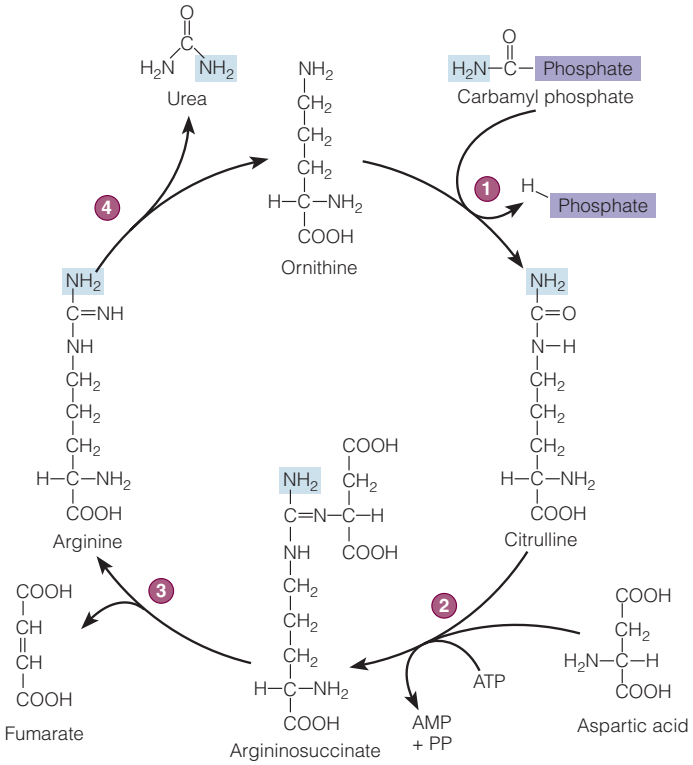

Figure C-7 shows the cycle of four reactions that follow.

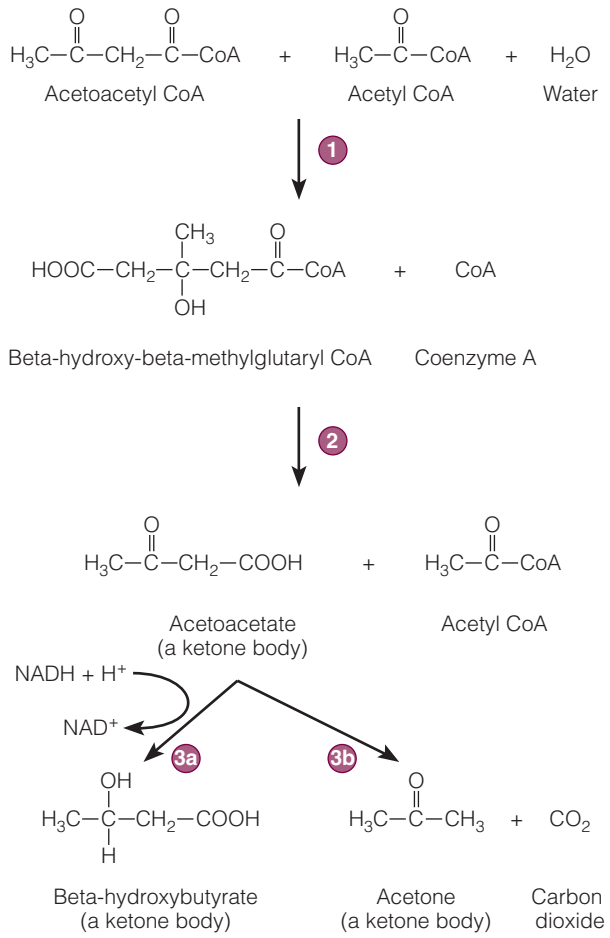
1. Carbamyl phosphate combines with the amino acid ornithine, losing its phosphate group. The compound formed is citrulline.
2. Citrulline combines with the amino acid aspartic acid, to form argininosuccinate. The reaction requires energy from ATP. (ATP was shown earlier losing one phosphorus atom in a phosphate group, P, to become ADP. In this reaction, it loses two phosphorus atoms joined together, PP, and becomes adenosine monophosphate, AMP.)
3. Argininosuccinate is split, forming another acid, fumarate, and the amino acid arginine.
4. Arginine loses its terminal carbon with two attached amino groups and picks up an oxygen from water. The end product is urea, which the kidneys excrete in the urine. The compound that remains is ornithine, identical to the ornithine with which this series of reactions began, and ready to react with another molecule of carbamyl phosphate and turn the cycle again.

Formation of Ketone Bodies

Normally, fatty acid oxidation proceeds all the way to carbon dioxide and water. However, in ketosis (discussed in Chapter 7), an intermediate is formed from the condensation of two molecules of acetyl CoA: acetoacetyl CoA. Figure C-8 shows the formation of ketone bodies from that intermediate.

FIGURE C-8 The Formation of Ketone Bodies



1. Acetoacetyl CoA condenses with acetyl CoA to form a six-carbon intermediate, beta-hydroxy-betamethylglutaryl CoA.
2. This intermediate is cleaved to acetyl CoA and acetoacetate.
3. Acetoactate can be metabolized either to beta-hydroxybutyrate acid (step 3a) or to acetone (3b).

Acetoacetate, beta-hydroxybutyrate, and acetone are the ketone bodies of ketosis. Two are real ketones (they have a C=O group between two carbons); the other is an alcohol that has been produced during ketone formation—hence the term *ketone bodies,* rather than ketones, to describe the three of them. There are many other ketones in nature; these three are characteristic of ketosis in the body.

Amino Acid Scoring
PDCAAS
Biological Value
Net Protein Utilizatin
Protein Efficiency Ratio

GLOSSARY

amino acid scoring: a measure of protein quality assessed by comparing a protein's amino acid pattern with that of a reference protein; sometimes called **chemical scoring.**

biological value (BV): a measure of protein quality assessed by measuring the amount of protein nitrogen that is retained from a given amount of protein nitrogen absorbed.

net protein utilization (NPU): a measure of protein quality assessed by measuring the amount of protein nitrogen that is retained from a given amount of protein nitrogen eaten.

PDCAAS (protein digestibility–corrected amino acid score): a measure of protein quality assessed by comparing the amino acid score of a food protein with the amino acid requirements of preschool-age children and then correcting for the true digestibility of the protein; recommended by the FAO/WHO and used to establish protein quality of foods for Daily Value percentages on food labels.

protein efficiency ratio (PER): a measure of protein quality assessed by determining how well a given protein supports weight gain in growing rats; used to establish the protein quality for infant formulas and baby foods.

Measures of Protein Quality

In a world where food is scarce and many people's diets contain marginal or inadequate amounts of protein, it is important to know which foods contain the highest-quality protein. Chapter 6 describes protein quality, and this appendix presents different measures researchers use to assess the quality of a food protein. The accompanying glossary defines related terms.

Amino Acid Scoring

Amino acid scoring evaluates a protein's quality by determining its amino acid composition and comparing it with that of a reference protein. The advantages of amino acid scoring are that it is simple and inexpensive, it easily identifies the limiting amino acid, and it can be used to score mixtures of different proportions of two or more proteins mathematically without having to make up a mixture and test it. Its chief weaknesses are that it fails to estimate the digestibility of a protein, which may strongly affect the protein's quality; it relies on a chemical procedure in which certain amino acids may be destroyed, making the pattern that is analyzed inaccurate; and it is blind to other features of the protein (such as the presence of substances that may inhibit the digestion or utilization of the protein) that would only be revealed by a test in living animals.

Table D-1 (p. D-1) shows the reference pattern for the nine essential amino acids. To interpret the table, read, "For every 3210 units of essential amino acids, 145 must be histidine, 340 must be isoleucine, 540 must be leucine," and so on. To compare a test protein with the reference protein, the experimenter first obtains a chemical analysis of the test protein's amino acids. Then, taking 3210 units of the amino acids, the experimenter compares the amount of each amino acid to the amount found in 3210 units of essential amino acids in egg protein. For example, suppose the test protein contained (per 3210 units) 360 units of isoleucine; 500 units of leucine; 350 of lysine; and for each of the other amino acids, more units than egg protein contains. The two amino acids that are low are leucine (500 as compared with 540 in egg) and lysine (350 versus 440 in egg). The ratio, amino acid in the test protein divided by amino acid in egg, is 500/540 (or about 0.93) for leucine and 350/440 (or about 0.80) for lysine. Lysine is the limiting amino acid (the one that falls shortest compared with egg). If the protein's limiting amino acid is 80 percent of the amount found in the reference protein, it receives a score of 80.

PDCAAS

The **protein digestibility–corrected amino acid score,** or **PDCASS**, compares the amino acid composition of a protein with human amino acid requirements and corrects for digestibility. First the protein's amino acid composition is determined, and then it is compared against the amino acid requirements of preschool-age children. This comparison reveals the most limiting amino acid—the one that falls shortest compared with the reference. If a food protein's limiting amino acid is 70 percent of the amount found in the reference protein, it receives a score of 70. The amino acid score is multiplied by the food's protein digestibility percentage to determine the PDCAAS. The box on p. D-2 provides an example of how to calculate the PDCAAS, and Table D-2 (p. D-1) lists the PDCAAS values of selected foods.

Biological Value

The **biological value (BV)** of a protein measures its efficiency in supporting the body's needs. In a test of biological value, two nitrogen balance studies are done. In

the first, no protein is fed, and nitrogen (N) excretions in the urine and feces are measured. It is assumed that under these conditions, N lost in the urine is the amount the body always necessarily loses by filtration into the urine each day, regardless of what protein is fed (endogenous N). The N lost in the feces (called metabolic N) is the amount the body invariably loses into the intestine each day, whether or not food protein is fed. (To help you remember the terms: endogenous N is "urinary N on a zero-protein diet"; metabolic N is "fecal N on a zero-protein diet.")

In the second study, an amount of protein slightly below the requirement is fed. Intake and losses are measured; then the BV is derived using this formula:

$$\text{BV} = \frac{\text{N retained}}{\text{N absorbed}} \times 100$$

The denominator of this equation expresses the amount of nitrogen *absorbed:* food N minus fecal N (excluding the metabolic N the body would lose in the feces anyway, even without food). The numerator expresses the amount of N *retained* from the N absorbed: absorbed N (as in the denominator) minus the N excreted in the urine (excluding the endogenous N the body would lose in the urine anyway, even without food). The more nitrogen retained, the higher the protein quality. (Recall that when an essential amino acid is missing, protein synthesis stops, and the remaining amino acids are deaminated and the nitrogen excreted.)

Egg protein has a BV of 100, indicating that 100 percent of the nitrogen absorbed is retained. Supplied in adequate quantity, a protein with a BV of 70 or greater can support human growth as long as energy intake is adequate. Table D-3 presents the BV for selected foods.

This method has the advantages of being based on experiments with human beings (it can be done with animals, too, of course) and of measuring actual nitrogen retention. But it is also cumbersome, expensive, and often impractical, and it is based on several assumptions that may not be valid. For example, the physiology, normal environment, or typical food intake of the subjects used for testing may not be similar to those for whom the test protein may ultimately be used. For another example, the retention of protein in the body does not necessarily mean that it is being well utilized. Considerable exchange of protein among tissues (protein turnover) occurs, but is hidden from view when only N intake and output are measured. The test of biological value wouldn't detect if one tissue were shorted.

Net Protein Utilization

Like BV, **net protein utilization (NPU)** measures how efficiently a protein is used by the body and involves two balance studies. The difference is that NPU measures retention of food nitrogen rather than food nitrogen absorbed (as in BV). The formula for NPU is:

$$\text{NPU} = \frac{\text{N retained}}{\text{N intake}} \times 100$$

The numerator is the same as for BV, but the denominator represents food N intake only—not N absorbed.

This method offers advantages similar to those of BV determinations and is used more frequently, with animals as the test subjects. A drawback is that if a low NPU is obtained, the test results offer no help in distinguishing between two possible causes: a poor amino acid composition of the test protein or poor digestibility. There is also a limit to the extent to which animal test results can be assumed to be applicable to human beings.

TABLE D-1 A Reference Pattern for Amino Acid Scoring of Proteins

Essential Amino Acids	Reference Protein—Whole Egg (mg amino acid/g nitrogen)
Histidine	145
Isoleucine	340
Leucine	540
Lysine	440
Methionine + cystine[a]	355
Phenylalanine + tyrosine[b]	580
Threonine	294
Tryptophan	106
Valine	410
Total	3210

[a]Methionine is essential and is also used to make cystine. Thus the methionine requirement is lower if cystine is supplied.
[b]Phenylalanine is essential and is also used to make tyrosine if not enough of the latter is available. Thus the phenylalanine requirement is lower if tyrosine is also supplied.

TABLE D-2 PDCAAS Values of Selected Foods

Casein (milk protein)	1.00
Egg white	1.00
Soybean (isolate)	.99
Beef	.92
Pea flour	.69
Kidney beans (canned)	.68
Chickpeas (canned)	.66
Pinto beans (canned)	.66
Rolled oats	.57
Lentils (canned)	.52
Peanut meal	.52
Whole wheat	.40

NOTE: 1.0 is the maximum PDCAAS a food protein can receive.

TABLE D-3 Biological Values (BV) of Selected Foods

Egg	100
Milk	93
Beef	75
Fish	75
Corn	72

NOTE: 100 is the maximum BV a food protein can receive.

HOW TO Measure Protein Quality Using PDCAAS

To calculate the PDCAAS (protein digestibility–corrected amino acid score), researchers first determine the amino acid profile of the test protein (in this example, pinto beans). The second column of the table below presents the essential amino acid profile for pinto beans. The third column presents the amino acid reference pattern.

To determine how well the food protein meets human needs, researchers calculate the ratio by dividing the second column by the third column (for example, 30 ÷ 18 = 1.67). The amino acid with the lowest ratio is the most limiting amino acid—in this case, methionine. Its ratio is the amino acid score for the protein—in this case, 0.84.

The amino acid score alone, however, does not account for digestibility. Protein digestibility, as determined by rat studies, yields a value of 79 percent for pinto beans. Together, the amino acid score and the digestibility value determine the PDCAAS:

PDCAAS = protein digestibility × amino acid score

PDCAAS for pinto beans = 0.79 × 0.84 = 0.66

Thus the PDCAAS for pinto beans is 0.66. Table D-2 lists the PDCAAS values of selected foods.

The PDCAAS is used to determine the % Daily Value on food labels. To calculate the % Daily Value for protein for canned pinto beans, multiply the number of grams of protein in a standard serving (in the case of pinto beans, 7 grams per ½ cup) by the PDCAAS:

7 g × 0.66 = 4.62

This value is then divided by the recommended standard for protein (for children over age four and adults, 50 grams):

4.62 ÷ 50 = 0.09 (or 9%)

The food label for this can of pinto beans would declare that one serving provides 7 grams protein, and if the label included a % Daily Value for protein (which is optional), the value would be 9 percent.

Essential Amino Acids	Amino Acid Profile of Pinto Beans (mg/g protein)	Amino Acid Reference Pattern (mg/g protein)	Amino Acid Score
Histidine	30.0	18	1.67
Isoleucine	42.5	25	1.70
Leucine	80.4	55	1.46
Lysine	69.0	51	1.35
Methionine (+ cystine)	21.1	25	0.84
Phenylalanine (+ tyrosine)	90.5	47	1.93
Threonine	43.7	27	1.62
Tryptophan	8.8	7	1.26
Valine	50.1	32	1.57

Appendix D

TABLE D-4 Protein Efficiency Ratio (PER) Values of Selected Proteins

Casein (milk)	2.8
Soy	2.4
Glutein (wheat)	0.4

Protein Efficiency Ratio

The **protein efficiency ratio (PER)** measures the weight gain of a growing animal and compares it to the animal's protein intake. Until recently, the PER was generally accepted in the United States and Canada as the official method for assessing protein quality, and it is still used to evaluate proteins for infants.

Young rats are fed a measured amount of protein and weighed periodically as they grow. The PER is expressed as:

$$\text{PER} = \frac{\text{weight gain (g)}}{\text{protein intake (g)}}$$

This method has the virtues of economy and simplicity, but it also has many drawbacks. The experiments are time-consuming; the amino acid needs of rats are not the same as those of human beings; and the amino acid needs for growth are not the same as for the maintenance of adult animals (growing animals need more lysine, for example). Table D-4 presents PER values for selected foods.

Nutrition Assessment: Supplemental Information

Chapter 17 described data from nutrition assessments that help health professionals evaluate patients' nutrition status and nutrient needs. This appendix provides additional information that may be useful for complete assessments.

Cautions about Nutrition Assessment

Growth Charts

Health professionals generally evaluate physical development by monitoring the growth rate of a child and comparing this rate with those on standard charts. Standard charts compare length or height to age, weight to age, weight to length, head circumference to age, and body mass index (BMI) ◆ to age. Although individual growth patterns may vary, a child's growth curve will generally stay at about the same percentile throughout childhood. In children whose growth has been retarded, nutrition rehabilitation will ideally induce height and weight to increase to higher percentiles. In overweight children, the goal is for weight to remain stable as height increases, until weight becomes appropriate for height.

To evaluate growth in infants, an assessor uses charts such as those in Figures E-1 (A and B) through E-3 (A and B) on pp. E-2 to E-4. ◆ The assessor follows these steps to plot a weight measurement on a percentile graph:

- Select the appropriate chart based on age and gender.
- Locate the child's age along the horizontal axis on the bottom of the chart.
- Locate the child's weight in pounds or kilograms along the vertical axis.
- Mark the chart where the age and weight lines intersect, and read off the percentile.

For other measures, the assessor follows a similar procedure, using the appropriate chart. (When length is measured, use the chart for birth to 36 months; when height is measured, use the chart for 2 to 20 years.) Once all of the measures are plotted on growth percentile charts, a skilled clinician can begin to interpret the data. Ideally, the height, weight, and head circumference should be in roughly the same percentile.

Percentile charts divide the measures of a population into 100 equal divisions. Thus half of the population falls above the 50th percentile, and half falls below. The use of percentile measures allows for comparisons among people of the same age and gender. For example, a six-month-old female infant whose weight is at the 75th percentile weighs more than 75 percent of the female infants her age.

Head circumference is generally measured in children under two years of age. Since the brain grows rapidly before birth and during early infancy, extreme and chronic malnutrition during these times can impair brain development, curtailing the number of brain cells and the size of head circumference. Nonnutritional factors, such as certain disorders and genetic variation, can also influence head circumference.

◆ Reminder: The *body mass index (BMI)* is an index of a person's weight in relation to height, determined by dividing the weight in kilograms by the square of the height in meters:

$$\text{BMI} = \frac{\text{Weight (kg)}}{\text{Height (m)}^2}$$

◆ Chapter 15 presents BMI charts for children and adolescents.

Measures of Body Fat and Lean Tissue

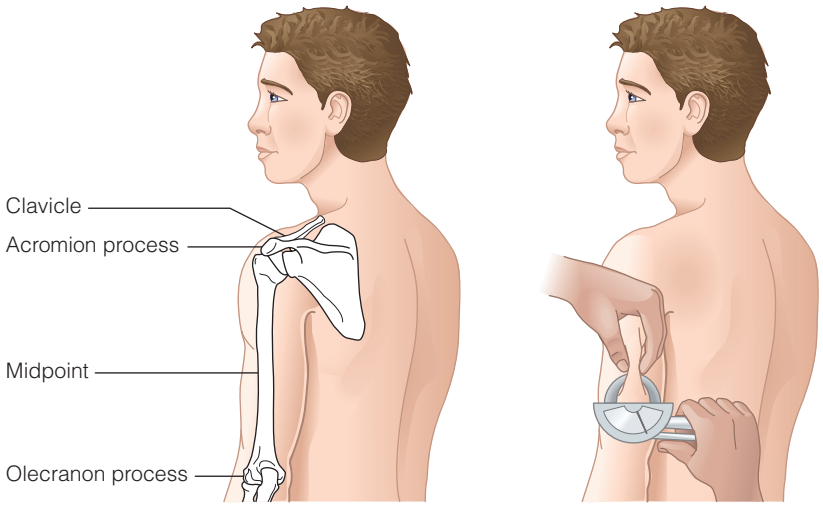
Significant weight changes in both children and adults can reflect overnutrition or undernutrition with respect to energy and protein. To estimate the degree to which fat stores or lean tissues are affected by malnutrition, several anthropometric measurements are useful.

Skinfold Measures Skinfold measures provide a good estimate of total body fat and a fair assessment of the fat's location. Most body fat lies directly beneath the skin, and the thickness of this subcutaneous fat correlates with total body fat. In some parts of the body, such as the back and the back of the arm over the triceps muscle, this fat is loosely attached. ◆ As illustrated in Figure E-4, an assessor can measure the thickness of the fat with calipers that apply a fixed amount of pressure. If a person gains body fat, the skinfold increases proportionately; if the person loses fat, it decreases. Measurements taken from central-body sites better reflect changes in fatness than those taken from upper sites (arm and back). Because subcutaneous fat may be thicker in one area than in another, skinfold measurements are often taken at three or four different places on the body (including upper-, central-, and lower-body sites); the sum of these measures is then compared to standard values. In some situations, the triceps skinfold measurement alone may be used because it is easily accessible. Triceps skinfold measures greater than 15 millimeters in men or 25 millimeters in women suggest excessive body fat.

◆ Common sites for skinfold measures:
- Triceps
- Biceps
- Subscapular (below shoulder blade)
- Suprailiac (above hip bone)
- Abdomen
- Upper thigh

Waist Circumference Chapter 8 described how fat distribution correlates with health risks and mentioned that the waist circumference is a valuable indicator of

FIGURE E-4 How to Measure the Triceps Skinfold



A. Find the midpoint of the arm:
1. Ask the subject to bend his or her arm at the elbow and lay the hand across the stomach. (If he or she is right-handed, measure the left arm, and vice versa.)
2. Feel the shoulder to locate the acromion process. It helps to slide your fingers along the clavicle to find the acromion process. The olecranon process is the tip of the elbow.
3. Place a measuring tape from the acromion process to the tip of the elbow. Divide this measurement by 2, and mark the midpoint of the arm with a pen.

B. Measure the skinfold:
1. Ask the subject to let his or her arm hang loosely to the side.
2. Grasp a fold of skin and subcutaneous fat between the thumb and forefinger slightly above the midpoint mark. Gently pull the skin away from the underlying muscle. (This step takes a lot of practice. If you want to be sure you don't have muscle as well as fat, ask the subject to contract and relax the muscle. You should be able to feel if you are pinching muscle.)
3. Place the calipers over the skinfold at the midpoint mark, and read the measurement to the nearest 1.0 millimeter in two to three seconds. (If using plastic calipers, align pressure lines, and read the measurement to the nearest 1.0 millimeter in two to three seconds.)
4. Repeat steps 2 and 3 twice more. Add the three readings, and then divide by 3 to find the average.

abdominal fat. To measure waist circumference, the assessor places a nonstretchable tape around the person's body, crossing just above the upper hip bones and making sure that the tape remains on a level horizontal plane on all sides (see Figure E-5). The tape is tightened slightly, but without compressing the skin.

Waist-to-Hip Ratio The waist-to-hip ratio assesses abdominal obesity, but it offers no advantage over the waist circumference alone. To calculate the waist-to-hip ratio, divide the waistline measurement by the hip measurement. ◆ In general, women with a waist-to-hip ratio of 0.8 or greater and men with a waist-to-hip ratio of 0.9 or greater have an increased risk of developing diabetes and cardiovascular diseases.

◆ The calculation of waist-to-hip ratio in a woman with a 28-inch waist and 38-inch hips is 28 ÷ 38 = 0.74.

Hydrodensitometry To estimate body density using hydrodensitometry, the person is weighed twice—first on land and then again when submerged in water. Underwater weighing usually generates a good estimate of body fat and is useful in research, although the technique has drawbacks: it requires bulky, expensive, and nonportable equipment. Furthermore, submerging some people in water (especially those who are very young, very old, ill, or fearful) is difficult and not well tolerated.

Bioelectrical Impedance To measure body fat using the bioelectrical impedance technique, a very-low-intensity electrical current is briefly sent through the body by way of electrodes placed on the wrist and ankle. Fat impedes the flow of electricity; thus the magnitude of the current is influenced by the body fat content. Recent food intake and hydration status can influence results. As with other anthropometric techniques, bioelectrical impedance requires standardized procedures and calibrated instruments.

FIGURE E-5 How to Measure Waist Circumference

Place the measuring tape around the waist just above the bony crest of the hip. The tape runs parallel to the floor and is snug (but does not compress the skin). The measurement is taken at the end of normal expiration.

TABLE E-1 Methods of Estimating Body Fat Content and Distribution

Method	Cost	Ease of Use	Accuracy	Measures Fat Distribution
Height and weight	Low	Easy	High	No
Skinfolds	Low	Easy	Low	Yes
Circumferences	Low	Easy	Moderate	Yes
Ultrasound	Moderate	Moderate	Moderate	Yes
Hydrodensitometry	Low	Moderate	High	No
Heavy water tritiated	Moderate	Moderate	High	No
Deuterium oxide, or heavy oxygen	High	Moderate	High	No
Potassium isotope (^{40}K)	Very high	Difficult	High	No
Total body electrical conductivity (TOBEC)	High	Moderate	High	No
Bioelectrical impedance (BIA)	Moderate	Easy	High	No
Dual energy X-ray absorptiometry (DEXA)	High	Easy	High	No
Computed tomography (CT)	Very high	Difficult	High	Yes
Magnetic resonance imaging (MRI)	Very high	Difficult	High	Yes

SOURCE: Adapted with permisssion from G. A. Bray, a handout presented at the North American Association for the Study of Obesity and Emory University School of Medicine Conference on Obesity Update: Pathophysiology, Clinical Consequences, and Therapeutic Options, Atlanta, Georgia, August 31–September 2, 1992.

Clinicians use many other methods to estimate body fat and its distribution. Each has advantages and disadvantages, as Table E-1 summarizes.

Nutritional Anemias

Anemia, a symptom of a wide variety of nutrition- and nonnutrition-related disorders, is characterized by a reduced oxygen-carrying capacity of blood. Iron, folate, and vitamin B_{12} deficiencies—caused by inadequate intake, poor absorption, or abnormal metabolism of these nutrients—are the most common causes of nutritional anemias. Table E-2 on p. E-8 lists laboratory tests that distinguish among the various nutrition-related anemias. Some nonnutrition-related causes of anemia include massive blood loss, infections, hereditary blood disorders such as sickle-cell anemia, and chronic liver or kidney disease.

Assessment of Iron Status

Chapter 13 described the progression of iron deficiency in detail, ◆ as well as the roles of some of the proteins involved in iron metabolism. This section describes the various tests that assess iron status, and Table E-3 on p. E-8 provides acceptable values. Although other tests are more specific for detecting the early stages of iron deficiency, hemoglobin and hematocrit are most often used to detect iron-deficiency anemia because they are inexpensive and easily measured.

◆ Reminder: Iron deficiency progresses as follows:
1. Iron stores diminish
2. Transport iron decreases
3. Hemoglobin production falls

Serum Ferritin In the initial stage of iron deficiency, iron stores diminish. Iron is stored in the protein ferritin, which is located in the liver, spleen, and bone marrow. Serum ferritin values provide a noninvasive estimate of iron stores, because the ferritin levels in blood reflect the amounts stored in the tissues. Serum ferritin is not a reliable indicator of iron deficiency, however, because its concentrations are increased by infection, inflammation, alcohol consumption, and liver disease.

Serum Iron and Total Iron-Binding Capacity (TIBC) Early stages of iron deficiency are characterized by reduced levels of serum iron, which represent the amount

TABLE E-2 Laboratory Tests Useful for Evaluating Nutrition-Related Anemias

Test or Test Result	What It Reflects
For Anemia (general)	
Hemoglobin (Hg)	Total amount of hemoglobin in the red blood cells (RBC)
Hematocrit (Hct)	Percentage of RBC in the total blood volume
Red blood cell (RBC) count	Number of RBC
Mean corpuscular volume (MCV)	RBC size; helps to determine if anemia is microcytic (iron deficiency) or macrocytic (folate or vitamin B_{12} deficiency)
Mean corpuscular hemoglobin concentration (MCHC)	Hemoglobin concentration within the average RBC; helps to determine if anemia is hypochromic (iron deficiency) or normochromic (folate or vitamin B_{12} deficiency)
Bone marrow aspiration	The manufacture of blood cells in different developmental states
For Iron-Deficiency Anemia	
↓ Serum ferritin	Early deficiency state with depleted iron stores
↓ Transferrin saturation	Progressing deficiency state with diminished transport iron
↑ Erythrocyte protoporphyrin	Later deficiency state with limited hemoglobin production
For Folate-Deficiency Anemia	
↓ Serum folate	Progressing deficiency state
↓ RBC folate	Later deficiency state
For Vitamin B_{12}–Deficiency Anemia	
↓ Serum vitamin B_{12}	Progressing deficiency state
Schilling test	Absorption of vitamin B_{12}

TABLE E-3 Criteria for Assessing Iron Status

Laboratory Test	Acceptable Values	Effect of Iron Deficiency
Serum ferritin	Male: 20–250 ng/mL Female: 10–120 ng/mL	Lower than normal
Serum iron	Male: 60–175 µg/dL Female: 50–170 µg/dL	Lower than normal
Total iron-binding capacity	250–450 µg/dL	Higher than normal
Transferrin saturation	Male: 20–50% Female: 15–50%	Lower than normal
Erythrocyte protoporphyrin	< 70 µg/dL red blood cells	Higher than normal
Hemoglobin (Hb)	Male: 13.5–17.5 g/dL Female: 12.0–16.0 g/dL	Lower than normal
Hematocrit (Hct)	Male: 39–49% Female: 35–45%	Lower than normal
Mean corpuscular volume (MCV)	80–100 fL	Lower than normal

NOTE: ng = nanogram, µg = microgram, dL = deciliter, nmol = nanomoles, fL=femtoliter
SOURCES: L. Goldman and D. Ausiello, coeditors, *Cecil Medicine* (Philadelphia: Saunders, 2008), pp. 2983–2991; R. J. Wood and A. G. Ronnenberg, Iron, in M. E. Shils and coeditors, *Modern Nutrition in Health and Disease* (Baltimore: Lippincott Williams & Wilkins, 2006), pp. 248–270.

of iron bound to transferrin, the iron transport protein. Total iron-binding capacity (TIBC) is a measure of the total amount of iron that the transferrin in blood can carry; thus, it is an indirect measure of the transferrin content of blood. During iron deficiency, the liver produces more transferrin in an effort to increase iron transport capacity, and therefore iron depletion is characterized by an increase in TIBC. TIBC reflects liver function as well as changes in iron metabolism.

Transferrin Saturation The percentage of transferrin that is saturated with iron is an indirect measure derived from the serum iron and total iron-binding capacity measures, as follows:

$$\%\text{Transferrin} = \frac{\text{serum iron}}{\text{total iron-binding capacity}} \times 100$$

During iron deficiency, transferrin saturation decreases. The transferrin saturation value is a useful indicator of iron status because it includes information about both the iron and transferrin content of blood.

Erythrocyte Protoporphyrin The iron-containing molecule in hemoglobin is heme, which is formed from iron and protoporphyrin. Protoporphyrin accumulates in the blood when iron supplies are inadequate for the formation of heme. However, levels of protoporphyrin may also be increased when hemoglobin synthesis is impaired for other reasons, such as lead poisoning or inflammation.

Hemoglobin When iron stores become depleted, hemoglobin production is impaired, and symptoms of anemia may eventually develop. Hemoglobin's usefulness in evaluating iron status is limited, however, because hemoglobin concentrations drop fairly late in the development of iron deficiency, and other nutrient deficiencies and medical conditions can also alter hemoglobin concentrations.

Hematocrit The hematocrit is the percentage of the total blood volume occupied by red blood cells. To measure the hematocrit, a clinician spins the blood samples in a centrifuge to separate the red blood cells from the plasma. Low values indicate a reduced number or size of red blood cells. Although this test is not specific for iron status, it can help to detect the presence of iron-deficiency anemia.

Mean Corpuscular Volume (MCV) The hematocrit value divided by the red blood cell count provides a measure of the average size of a red blood cell, referred to as the mean corpuscular volume (MCV). Such a measure helps to classify the type of anemia that is present. In iron deficiency, the red blood cells are smaller than average (microcytic cells).

Assessment of Folate and Vitamin B_{12} Status

Folate deficiency and vitamin B_{12} deficiency present a similar clinical picture—an anemia characterized by abnormally large, misshapen, and immature red blood cells (megaloblastic cells). Distinguishing between folate and vitamin B_{12} deficiency is essential, however, because their treatments differ. Giving folate to a person with vitamin B_{12} deficiency improves many of the test results indicative of vitamin B_{12} deficiency, but this would be a dangerous treatment because vitamin B_{12} deficiency causes nerve damage that folate cannot correct. Thus, inappropriate folate administration masks vitamin B_{12}–deficiency anemia, and nerve damage worsens. For this reason, it is critical to determine whether the anemia results from a folate deficiency or from a vitamin B_{12} deficiency. Several of the following assessment measures help to make this distinction.

Mean Corpuscular Volume (MCV) As previously mentioned, MCV is a measure of red blood cell size. In folate and vitamin B_{12} deficiencies, the red blood cells are larger than average, or macrocytic. Macrocytic cells are not necessarily indicative of nutrient deficiency, however, as they may also result from a high alcohol intake, liver disease, and various medications.

Serum Folate and Vitamin B_{12} Levels Analyses of serum folate and vitamin B_{12} levels are usually among the first tests conducted to determine the cause of macrocytic red blood cells. The presence of low serum levels of either nutrient is consistent with a deficiency of that nutrient, whereas adequate levels can help to rule out deficiency. Folate levels are not a specific measure of folate status, however; they may increase after folate consumption, and decrease due to alcohol consumption, pregnancy, or use

of anticonvulsants. The folate levels in red blood cells (called erythrocyte folate) correlate well with folate stores and can help to diagnose folate deficiency, but the more reliable testing methods are not widely available. Table E-4 shows the acceptable ranges for these tests.

Methylmalonic Acid and Homocysteine Levels To determine whether a nutrient deficiency is present, clinicians can measure the levels of substances that accumulate when the functions of that nutrient are impaired. For example, blood levels of the amino acid homocysteine are usually increased by both folate and vitamin B_{12} deficiency, because both nutrients are needed for its metabolism. Methylmalonic acid, a breakdown product of several amino acids, requires vitamin B_{12} for its metabolism; hence, its levels accumulate in serum as a result of vitamin B_{12} deficiency. Because methylmalonic acid levels are not influenced by folate status, this measure is useful in distinguishing between folate and vitamin B_{12} deficiency.

Schilling Test As Chapter 10 explained, vitamin B_{12} deficiency most often results from malabsorption, not poor intake. The Schilling test helps to diagnose malabsorption of vitamin B_{12}. After the patient takes an oral dose of radioactive vitamin B_{12}, a urine test determines whether the vitamin B_{12} was absorbed. More extensive testing can determine the cause of malabsorption.

Cautions about Nutrition Assessment

The tests outlined in this appendix yield information that becomes meaningful only when conducted and interpreted by a skilled clinician. Potential sources of error may be introduced at any step, from the collection of samples to the analysis and reporting of data. Equipment must be regularly calibrated to ensure accuracy of measurements. In addition, the assessor must keep in mind that few tests may be specific to the nutrient of interest alone, and lab results may reflect physiological processes other than the ones being tested. Furthermore, many tests are not sensitive enough to detect the early stages of deficiency; thus follow-up testing is often necessary to identify a nutrition problem.

TABLE E-4 Criteria for Assessing Folate and Vitamin B_{12} Status

Laboratory Test	Acceptable Range	Effect of Folate or Vitamin B_{12} Deficiency
Serum folate	3–16 ng/mL	Reduced in folate deficiency
Erythrocyte folate	140–628 ng/mL packed cells	Reduced in folate deficiency
Serum vitamin B_{12}	200–835 pg/mL	Reduced in vitamin B_{12} deficiency
Serum methylmalonic acid	70–270 nmol/L	Increased in vitamin B_{12} deficiency
Serum homocysteine	5-–14 µmol/L	Increased in folate or vitamin B_{12} deficiency

NOTE: ng = nanogram, pg = picogram, nmol = nanomole, µmol = micromoles

Physical Activity and Energy Requirements

CONTENTS

Calculating Physical Activity Level
Estimating Physical Activity Level
Using a Shortcut to Estimate Total Energy Expenditure

Chapter 8 described how to calculate estimated energy requirements (EER) for adults by using an equation that accounts for gender, age, weight, height, and physical activity level. Table F-1 presents additional equations to determine the EER for infants, children, adolescents, and pregnant and lactating women.

This appendix helps you determine the correct physical activity (PA) factor to use in the equations, either by calculating the physical activity level or by estimating it. For those who prefer to bypass these steps, the appendix presents tables that provide a shortcut to estimating total energy expenditure.*

Calculating Physical Activity Level

To calculate your physical activity level, record all of your activities for a typical 24-hour day, noting the type of activity, the level of intensity, and the duration. Then, using a copy of Table F-2, find your activity in the first column (or an activity that is reasonably similar) and multiply the number of minutes spent on that activity by the factor in the third column. Put your answer in the last column and total the accumulated values for the day. Now add the subtotal of the last column to 1.1 (to account for basal energy and the thermic effect of food) as shown. This score indicates your physical activity level. Using Table F-3, find the PA factor for your age and gender that correlates with your physical activity level and use it in the energy equations presented in Table F-1.

Estimating Physical Activity Level

As an alternative to recording your activities for a day, you can use the third column of Table F-3 to decide if your daily activity is sedentary, low active, active, or very active. Find the PA factor for your age and gender that correlates with your typical physical activity level and use it in the energy equations presented in Table F-1.

Using a Shortcut to Estimate Total Energy Expenditure

The DRI Committee has developed estimates of total energy expenditure based on the equations for adults presented in Table F-1. These estimates are presented in Table F-4 for women and Table F-5 for men. You can use these tables to estimate your energy requirement—that is, the number of kcalories needed to maintain your current body weight. On the table appropriate for your gender, find your height in meters (or inches) in the left-hand column. Then follow the row across to find your weight in kilograms (or pounds). (If you can't find your exact height and weight, choose a value between the two closest ones.) Look down the column to find the number of kcalories that corresponds to your activity level.

Importantly, the values given in the tables are for 30-year-old people. Women 19 to 29 should add 7 kcalories per day for each year below age 30; older women should subtract 7 kcalories per day for each year above age 30. Similarly, men 19 to 29 should add 10 kcalories per day for each year below age 30; older men should subtract 10 kcalories per day for each year above age 30.

*This appendix, including the tables, is adapted from Committee on Dietary Reference Intakes, *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids* (Washington, D.C.: National Academies Press, 2002/2005).

TABLE F-1 Equations to Determine Estimated Energy Requirement (EER)

Infants	
0–3 months	EER = (89 × weight − 100) + 175
4–6 months	EER = (89 × weight − 100) + 56
7–12 months	EER = (89 × weight − 100) + 22
13–15 months	EER = (89 × weight − 100) + 20
Children and Adolescents	
Boys	
3–8 years	EER = 88.5 − (61.9 × age) + PA × [(26.7 × weight) + (903 × height)] + 20
9–18 years	EER = 88.5 − (61.9 × age) + PA × [(26.7 × weight) + (903 × height)] + 25
Girls	
3–8 years	EER = 135.3 − (30.8 × age) + PA × [(10.0 × weight) + (934 × height)] + 20
9–18 years	EER = 135.3 − (30.8 × age) + PA × [(10.0 × weight) + (934 × height)] + 25
Adults	
Men	EER = 662 − (9.53 × age) + PA × [(15.91 × weight) + (539.6 × height)]
Women	EER = 354 − (6.91 × age) + PA × [(9.36 × weight) + (726 × height)]
Pregnancy	
1st trimester	EER = nonpregnant EER + 0
2nd trimester	EER = nonpregnant EER + 340
3rd trimester	EER = nonpregnant EER + 452
Lactation	
0–6 months postpartum	EER = nonpregnant EER + 500 − 170
7–12 months postpartum	EER = nonpregnant EER + 400 − 0

NOTE: Select the appropriate equation for gender and age and insert weight in kilograms, height in meters, and age in years. See the text and Table F-3 to determine PA.

TABLE F-2 Physical Activities and Their Scores

If your activity was equivalent to this …	Then list the number of minutes here and …	Multiply by this factor …	Add this column to get your physical activity level score:
Activities of Daily Living			
Gardening (no lifting)		0.0032

Exchange Lists for Diabetes

Chapter 2 introduced the exchange system, and this appendix provides details from the *2008 Choose Your Foods: Exchange Lists for Diabetes*. Appendix I presents Canada's meal-planning system.

Exchange lists can help people with diabetes to manage their blood glucose levels by controlling the amount and kinds of carbohydrates they consume. These lists can also help in planning diets for weight management by controlling kcalorie and fat intake.

CONTENTS

The Exchange System
Serving Sizes
The Foods on the Lists
Controlling Energy, Fat, and Sodium
Planning a Healthy Diet

The Exchange System

The exchange system sorts foods into groups by their proportions of carbohydrate, fat, and protein (Table G-1 on p. G-2). These groups may be organized into several exchange lists of foods (Tables G-2 through G-12 on pp. G-3–G-16). For example, the carbohydrate group includes these exchange lists:

- Starch
- Fruits
- Milk (fat-free, reduced-fat, and whole)
- Sweets, Desserts, and Other Carbohydrates
- Nonstarchy Vegetables

Then any food on a list can be "exchanged" for any other on that same list. Another group for alcohol has been included as a reminder that these beverages often deliver substantial carbohydrate and kcalories, and therefore warrant their own list.

Serving Sizes

The serving sizes have been carefully adjusted and defined so that a serving of any food on a given list provides roughly the same amount of carbohydrate, fat, and protein, and, therefore, total energy. Any food on a list can thus be exchanged, or traded, for any other food on the same list without significantly affecting the diet's energy-nutrient balance or total kcalories. For example, a person may select 17 small grapes or $^1/_2$ large grapefruit as one fruit exchange, and either choice would provide roughly 15 grams of carbohydrate and 60 kcalories. A whole grapefruit, however, would count as 2 fruit exchanges.

To apply the system successfully, users must become familiar with the specified serving sizes. A convenient way to remember the serving sizes and energy values is to keep in mind a typical item from each list (review Table G-1).

The Foods on the Lists

Foods do not always appear on the exchange list where you might first expect to find them. They are grouped according to their energy-nutrient contents rather than by their source (such as milks), their outward appearance, or their vitamin and mineral contents. For example, cheeses are grouped with meats (not milk) because, like meats, cheeses contribute energy from protein and fat but provide negligible carbohydrate.

For similar reasons, starchy vegetables such as corn, green peas, and potatoes are found on the Starch list with breads and cereals, not with the vegetables. Likewise, bacon is grouped with the fats and oils, not with the meats.

Diet planners learn to view mixtures of foods, such as casseroles and soups, as combinations of foods from different exchange lists. They also learn to interpret food labels with the exchange system in mind.

Controlling Energy, Fat, and Sodium

The exchange lists help people control their energy intakes by paying close attention to serving sizes. People wanting to lose weight can limit foods from the Sweets, Desserts, and Other Carbohydrates and Fats lists, and they might choose to avoid the Alcohol list altogether. The Free Foods list provide low-kcalorie choices.

By assigning items like bacon to the Fats list, the exchange lists alert consumers to foods that are unexpectedly high in fat. Even the Starch list specifies which grain products contain added fat (such as biscuits, cornbread, and waffles) by marking them with a symbol to indicate added fat (the symbols are explained in the table keys). In addition, the exchange lists encourage users to think of fat-free milk as milk and of whole milk as milk with added fat, and to think of lean meats as meats and of medium-fat and high-fat meats as meats with added fat. To that end, foods on the milk and meat lists are separated into categories based on their fat contents (review Table G-1). The Milk list is subdivided for fat-free, reduced-fat, and whole; the meat list is subdivided for lean, medium-fat, and high-fat. The meat list also includes plant-based proteins, which tend to be rich in fiber. Notice that many of these foods (p. G-11) bear the symbol for "high fiber."

People wanting to control the sodium in their diets can begin by eliminating any foods bearing the "high sodium" symbol. In most cases, the symbol identifies foods that, in one serving, provide 480 milligrams or more of sodium. Foods on the "Combination Foods" or "Fast Foods" lists that bear the symbol provide more than 600 milligrams of sodium. Other foods may also contribute substantially to sodium (consult Chapter 12 for details).

TABLE G-1 The Food Lists

Lists	Typical Item/Portion Size	Carbohydrate (g)	Protein (g)	Fat (g)	Energy[a] (kcal)
Carbohydrates					
Starch[b]	1 slice bread	15	0–3	0–1	80
Fruits	1 small apple	15	—	—	60
Milk					
Fat-free, low-fat, 1%	1 c fat-free milk	12	8	0–3	100
Reduced-fat, 2%	1 c reduced-fat milk	12	8	5	120
Whole	1 c whole milk	12	8	8	160
Sweets, desserts, and other carbohydrates[c]	2 small cookies	15	varies	varies	varies
Nonstarchy vegetables	½ c cooked carrots	5	2	—	25
Meat and Meat Substitutes					
Lean	1 oz chicken (no skin)	—	7	0–3	45
Medium-fat	1 oz ground beef	—	7	4–7	75
High-fat	1 oz pork sausage	—	7	8+	100
Plant-based proteins	½ c tofu	varies	7	varies	varies
Fats	1 tsp butter	—	—	5	45
Alcohol	12 oz beer	varies	—	—	100

[a]The energy value for each exchange list represents an approximate average for the group and does not reflect the precise number of grams of carbohydrate, protein, and fat. For example, a slice of bread contains 15 grams of carbohydrate (60 kcalories), 3 grams protein (12 kcalories), and a little fat—rounded to 80 kcalories for ease in calculating. A half-cup of vegetables (not including starchy vegetables) contains 5 grams carbohydrate (20 kcalories) and 2 grams protein (8 more), which has been rounded down to 25 kcalories.
[b]The Starch list includes cereals, grains, breads, crackers, snacks, starchy vegetables (such as corn, peas, and potatoes), and legumes (dried beans, peas, and lentils).
[c]The Sweets, Desserts, and Other Carbohydrates list includes foods that contain added sugars and fats such as sodas, candy, cakes, cookies, doughnuts, ice cream, pudding, syrup, and frozen yogurt.

Planning a Healthy Diet

To obtain a daily variety of foods that provide healthful amounts of carbohydrate, protein, and fat, as well as vitamins, minerals, and fiber, the meal plan for adults and teenagers should include at least:

- 2 to 3 servings of nonstarchy vegetables
- 2 servings of fruits
- 6 servings of grains (at least 3 of whole grains), beans, and starchy vegetables
- 2 servings of low-fat or fat-free milk
- about 6 ounces of meat or meat substitutes
- *small* amounts of fat and sugar

The actual amounts are determined by age, gender, activity levels, and other factors that influence energy needs. Refer to Chapter 8 as you read through these sections to get an idea of how exchange lists can be useful in planning a diet.

TABLE G-2 Starch

The Starch list includes bread, cereals and grains, starchy vegetables, crackers and snacks, and legumes (dried beans, peas, and lentils).
1 starch choice = 15 g carbohydrate, 0–3 g protein, 0–1 g fat, and 80 kcal.
Note: In general, one starch exchange is 1/2 c cooked cereal, grain, or starchy vegetable; 1/3 c cooked rice or pasta; 1 oz of bread product; 3/4 oz to 1 oz of most snack foods.

Bread

Food	Serving Size
Bagel, large (about 4 oz)	1/4 (1 oz)
▽ Biscuit, 2 1/2 inches across	1
Bread	
☺ reduced-kcalorie	2 slices (1 1/2 oz)
white, whole-grain, pumpernickel, rye, unfrosted raisin	1 slice (1 oz)
Chapatti, small, 6 inches across	1
▽ Cornbread, 1 3/4 inch cube	1 (1 1/2 oz)
English muffin	1/2
Hot dog bun or hamburger bun	1/2 (1 oz)
Naan, 8 inches by 2 inches	1/4
Pancake, 4 inches across, 1/4 inch thick	1
Pita, 6 inches across	1/2
Roll, plain, small	1 (1 oz)
▽ Stuffing, bread	1/3 cup
▽ Taco shell, 5 inches across	2
Tortilla, corn, 6 inches across	1
Tortilla, flour, 6 inches across	1
Tortilla, flour, 10 inches across	1/3
▽ Waffle, 4-inch square or 4 inches across	1

Cereals and Grains

Food	Serving Size
Barley, cooked	1/3 cup
Bran, dry	
☺ oat	1/4 cup
☺ wheat	1/2 cup
☺ Bulgur (cooked)	1/2 cup
Cereals	
☺ bran	1/2 cup
cooked (oats, oatmeal)	1/2 cup
puffed	1 1/2 cups
shredded wheat, plain	1/2 cup
sugar-coated	1/2 cup
unsweetened, ready-to-eat	3/4 cup
Couscous	1/3 cup
Granola	
low-fat	1/4 cup
▽ regular	1/4 cup
Grits, cooked	1/2 cup
Kasha	1/2 cup
Millet, cooked	1/3 cup
Muesli	1/4 cup
Pasta, cooked	1/3 cup

KEY

☺ = More than 3 grams of dietary fiber per serving.
▽ = Extra fat, or prepared with added fat. (Count as 1 starch + 1 fat.)
▯ = 480 milligrams or more of sodium per serving.

TABLE G-2 Starch—*continued*

Cereals and Grains

Food	Serving Size
Polenta, cooked	1/3 cup
Quinoa, cooked	1/3 cup
Rice, white or brown, cooked	1/3 cup
Tabbouleh (tabouli), prepared	1/2 cup
Wheat germ, dry	3 Tbsp
Wild rice, cooked	1/2 cup

Starchy Vegetables

Food	Serving Size
Cassava	1/3 cup
Corn	1/2 cup
on cob, large	1/2 cob (5 oz)
Hominy, canned	3/4 cup
Mixed vegetables with corn, peas, or pasta	1 cup
Parsnips	1/2 cup
Peas, green	1/2 cup
Plantain, ripe	1/3 cup
Potato	
baked with skin	1/4 large (3 oz)
boiled, all kinds	1/2 cup or 1/2 medium (3 oz)
mashed, with milk and fat	1/2 cup
French fried (oven-baked)[a]	1 cup (2 oz)
Pumpkin, canned, no sugar added	1 cup
Spaghetti/pasta sauce	1/2 cup
Squash, winter (acorn, butternut)	1 cup
Succotash	1/2 cup
Yam, sweet potato, plain	1/2 cup

Crackers and Snacks[b]

Food	Serving Size
Animal crackers	8
Crackers	
round-butter type	6
saltine-type	6
sandwich-style, cheese or peanut butter filling	3
whole-wheat regular	2–5 (3/4 oz)
whole-wheat lower fat or crispbreads	2–5 (3/4 oz)

Crackers and Snacks[b]

Food	Serving Size
Graham cracker, 2 1/2-inch square	3
Matzoh	3/4 oz
Melba toast, about 2-inch by 4-inch piece	4
Oyster crackers	20
Popcorn	3 cups
with butter	3 cups
no fat added	3 cups
lower fat	3 cups
Pretzels	3/4 oz
Rice cakes, 4 inches across	2
Snack chips	
fat-free or baked (tortilla, potato), baked pita chips	15–20 (3/4 oz)
regular (tortilla, potato)	9–13 (3/4 oz)

Beans, Peas, and Lentils[c]

The choices on this list count as 1 starch + 1 lean meat.

Food	Serving Size
Baked beans	1/3 cup
Beans, cooked (black, garbanzo, kidney, lima, navy, pinto, white)	1/2 cup
Lentils, cooked (brown, green, yellow)	1/2 cup
Peas, cooked (black-eyed, split)	1/2 cup
Refried beans, canned	1/2 cup

KEY

= More than 3 grams of dietary fiber per serving.
= Extra fat, or prepared with added fat. (Count as 1 starch + 1 fat.)
= 480 milligrams or more of sodium per serving.

[a]Restaurant-style French fries are on the Fast Foods list.
[b]For other snacks, see the Sweets, Desserts, and Other Carbohydrates list. For a quick estimate of serving size, an open handful is equal to about 1 cup or 1 to 2 ounces of snack food.
[c]Beans, peas, and lentils are also found on the Meat and Meat Substitutes list.

TABLE G-3 Fruits

Fruit[a]

The Fruits list includes fresh, frozen, canned, and dried fruits and fruit juices. 1 fruit choice = 15 g carbohydrate, 0 g protein, 0 g fat, and 60 kcal.
Note: In general, one fruit exchange is 1/2 c canned or fresh fruit or unsweetened fruit juice; 1 small fresh fruit (4 oz); 2 Tbsp dried fruit.

Food	Serving Size
Apple, unpeeled, small	1 (4 oz)
Apples, dried	4 rings
Applesauce, unsweetened	1/2 cup
Apricots	
canned	1/2 cup
dried	8 halves
☺ fresh	4 whole (5 1/2 oz)
Banana, extra small	1 (4 oz)
☺ Blackberries	3/4 cup
Blueberries	3/4 cup
Cantaloupe, small	1/3 melon or 1 cup cubed (11 oz)
Cherries	
sweet, canned	1/2 cup
sweet fresh	12 (3 oz)
Dates	3
Dried fruits (blueberries, cherries, cranberries, mixed fruit, raisins)	2 Tbsp
Figs	
dried	1 1/2
☺ fresh	1 1/2 large or 2 medium (3 1/2 oz)
Fruit cocktail	1/2 cup
Grapefruit	
large	1/2 (11 oz)
sections, canned	3/4 cup
Grapes, small	17 (3 oz)
Honeydew melon	1 slice or 1 cup cubed (10 oz)
☺ Kiwi	1 (3 1/2 oz)
Mandarin oranges, canned	3/4 cup
Mango, small	1/2 (5 1/2 oz) or 1/2 cup
Nectarine, small	1 (5 oz)
☺ Orange, small	1 (6 1/2 oz)
Papaya	1/2 or 1 cup cubed (8 oz)
Peaches	
canned	1/2 cup
fresh, medium	1 (6 oz)
Pears	
canned	1/2 cup
fresh, large	1/2 (4 oz)
Pineapple	
canned	1/2 cup
fresh	3/4 cup
Plums	
canned	1/2 cup
dried (prunes)	3
small	2 (5 oz)
☺ Raspberries	1 cup
☺ Strawberries	1 1/4 cup whole berries
☺ Tangerines, small	2 (8 oz)
Watermelon	1 slice or 1 1/4 cups cubes (13 1/2 oz)

Fruit Juice

Food	Serving Size
Apple juice/cider	1/2 cup
Fruit juice blends, 100% juice	1/3 cup
Grape juice	1/3 cup
Grapefruit juice	1/2 cup
Orange juice	1/2 cup
Pineapple juice	1/2 cup
Prune juice	1/3 cup

KEY

☺ = More than 3 grams of dietary fiber per serving.
▽ = Extra fat, or prepared with added fat.
▯ = 480 milligrams or more of sodium per serving.

[a]The weight listed includes skin, core, seeds, and rind.

TABLE G-4 Milk

The Milk list groups milks and yogurts based on the amount of fat they have (fat-free/low-fat, reduced-fat, and whole). Cheeses are found on the Meat and Meat Substitutes list and cream and other dairy fats are found on the Fats list.

Note: In general, one milk choice is 1 cup (8 fluid ounces or 1/2 pint) milk or yogurt.

Milk and Yogurts

Food	Serving Size
Fat-free or low-fat (1%)	
1 fat-free/low-fat milk choice = 12 g carbohydrate, 8 g protein, 0–3 g fat, and 100 kcal.	
Milk, buttermilk, acidophilus milk, Lactaid	1 cup
Evaporated milk	1/2 cup
Yogurt, plain or flavored with an artificial sweetener	2/3 cup (6 oz)
Reduced-fat (2%)	
1 reduced-fat milk choice = 12 g carbohydrate, 8 g protein, 5 g fat, and 120 kcal.	
Milk, acidophilus milk, kefir, Lactaid	1 cup
Yogurt, plain	2/3 cup (6 oz)
Whole	
1 whole milk choice = 12 g carbohydrate, 8 g protein, 8 g fat, and 160 kcal.	
Milk, buttermilk, goat's milk	1 cup
Evaporated milk	1/2 cup
Yogurt, plain	8 oz

Dairy-Like Foods

Food	Serving Size	Count as
Chocolate milk		
fat-free	1 cup	1 fat-free milk + 1 carbohydrate
whole	1 cup	1 whole milk + 1 carbohydrate
Eggnog, whole milk	1/2 cup	1 carbohydrate + 2 fats
Rice drink		
flavored, low-fat	1 cup	2 carbohydrates
plain, fat-free	1 cup	1 carbohydrate
Smoothies, flavored, regular	10 oz	1 fat-free milk + 2 1/2 carbohydrates
Soy milk		
light	1 cup	1 carbohydrate + 1/2 fat
regular, plain	1 cup	1 carbohydrate + 1 fat
Yogurt		
and juice blends	1 cup	1 fat-free milk + 1 carbohydrate
low carbohydrate (less than 6 grams carbohydrate per choice)	2/3 cup (6 oz)	1/2 fat-free milk
with fruit, low-fat	2/3 cup (6 oz)	1 fat-free milk + 1 carbohydrate

TABLE G-5 Sweets, Desserts, and Other Carbohydrates

1 other carbohydrate choice = 15 g carbohydrate, variable grams protein, variable grams fat, and variable kcalories.
Note: In general, one choice from this list can substitute for foods on the Starch, Fruits, or Milk lists.

Beverages, Soda, and Energy/Sports Drinks

Food	Serving Size	Count as
Cranberry juice cocktail	1/2 cup	1 carbohydrate
Energy drink	1 can (8.3 oz)	2 carbohydrates
Fruit drink or lemonade	1 cup (8 oz)	2 carbohydrates
Hot chocolate		
regular	1 envelope added to 8 oz water	1 carbohydrate + 1 fat
sugar-free or light	1 envelope added to 8 oz water	1 carbohydrate
Soft drink (soda), regular	1 can (12 oz)	2 1/2 carbohydrates
Sports drink	1 cup (8 oz)	1 carbohydrate

Brownies, Cake, Cookies, Gelatin, Pie, and Pudding

Food	Serving Size	Count as
Brownie, small, unfrosted	1 1/4-inch square, 7/8 inch high (about 1 oz)	1 carbohydrate + 1 fat
Cake		
angel food, unfrosted	1/12 of cake (about 2 oz)	2 carbohydrates
frosted	2-inch square (about 2 oz)	2 carbohydrates + 1 fat
unfrosted	2-inch square (about 2 oz)	1 carbohydrate + 1 fat
Cookies		
chocolate chip	2 cookies (2 1/4 inches across)	1 carbohydrate + 2 fats
gingersnap	3 cookies	1 carbohydrate
sandwich, with crème filling	2 small (about 2/3 oz)	1 carbohydrate + 1 fat
sugar-free	3 small or 1 large (3/4–1 oz)	1 carbohydrate + 1–2 fats
vanilla wafer	5 cookies	1 carbohydrate + 1 fat
Cupcake, frosted	1 small (about 1 3/4 oz)	2 carbohydrates + 1–1 1/2 fats
Fruit cobbler	1/2 cup (3 1/2 oz)	3 carbohydrates + 1 fat
Gelatin, regular	1/2 cup	1 carbohydrate
Pie		
commercially prepared fruit, 2 crusts	1/6 of 8-inch pie	3 carbohydrates + 2 fats
pumpkin or custard	1/8 of 8-inch pie	1 1/2 carbohydrates + 1 1/2 fats
Pudding		
regular (made with reduced-fat milk)	1/2 cup	2 carbohydrates
sugar-free or sugar- and fat-free (made with fat-free milk)	1/2 cup	1 carbohydrate

Candy, Spreads, Sweets, Sweeteners, Syrups, and Toppings

Food	Serving Size	Count as
Candy bar, chocolate/peanut	2 "fun size" bars (1 oz)	1 1/2 carbohydrates + 1 1/2 fats
Candy, hard	3 pieces	1 carbohydrate
Chocolate "kisses"	5 pieces	1 carbohydrate + 1 fat
Coffee creamer		
dry, flavored	4 tsp	1/2 carbohydrate + 1/2 fat
liquid, flavored	2 Tbsp	1 carbohydrate

(continued)

TABLE G-5 Sweets, Desserts, and Other Carbohydrates—*continued*

Candy, Spreads, Sweets, Sweeteners, Syrups, and Toppings

Food	Serving Size	Count as
Fruit snacks, chewy (pureed fruit concentrate)	1 roll (3/4 oz)	1 carbohydrate
Fruit spreads, 100% fruit	1 1/2 Tbsp	1 carbohydrate
Honey	1 Tbsp	1 carbohydrate
Jam or jelly, regular	1 Tbsp	1 carbohydrate
Sugar	1 Tbsp	1 carbohydrate
Syrup		
chocolate	2 Tbsp	2 carbohydrates
light (pancake type)	2 Tbsp	1 carbohydrate
regular (pancake type)	1 Tbsp	1 carbohydrate

Condiments and Sauces[a]

Food	Serving Size	Count as
Barbeque sauce	3 Tbsp	1 carbohydrate
Cranberry sauce, jellied	1/4 cup	1 1/2 carbohydrates
Gravy, canned or bottled	1/2 cup	1/2 carbohydrate + 1/2 fat
Salad dressing, fat-free, low-fat, cream-based	3 Tbsp	1 carbohydrate
Sweet and sour sauce	3 Tbsp	1 carbohydrate

Doughnuts, Muffins, Pastries, and Sweet Breads

Food	Serving Size	Count as
Banana nut bread	1-inch slice (1 oz)	2 carbohydrates + 1 fat
Doughnut		
cake, plain	1 medium (1 1/2 oz)	1 1/2 carbohydrates + 2 fats
yeast type, glazed	3 3/4 inches across (2 oz)	2 carbohydrates + 2 fats
Muffin (4 oz)	1/4 muffin (1 oz)	1 carbohydrate + 1/2 fat
Sweet roll or Danish	1 (2 1/2 oz)	2 1/2 carbohydrates + 2 fats

Frozen Bars, Frozen Desserts, Frozen Yogurt, and Ice Cream

Food	Serving Size	Count as
Frozen pops	1	1/2 carbohydrate
Fruit juice bars, frozen, 100% juice	1 bar (3 oz)	1 carbohydrate
Ice cream		
fat-free	1/2 cup	1 1/2 carbohydrates
light	1/2 cup	1 carbohydrate + 1 fat
no sugar added	1/2 cup	1 carbohydrate + 1 fat
regular	1/2 cup	1 carbohydrate + 2 fats
Sherbet, sorbet	1/2 cup	2 carbohydrates
Yogurt, frozen		
fat-free	1/3 cup	1 carbohydrate
regular	1/2 cup	1 carbohydrate + 0–1 fat

KEY

= 480 milligrams or more of sodium per serving.

[a] You can also check the Fats list and Free Foods list for other condiments.

TABLE G-5 Sweets, Desserts, and Other Carbohydrates—*continued*

Granola Bars, Meal Replacement Bars/Shakes, and Trail Mix

Food	Serving Size	Count as
Granola or snack bar, regular or low-fat	1 bar (1 oz)	1 1/2 carbohydrates
Meal replacement bar	1 bar (1 1/3 oz)	1 1/2 carbohydrates + 0–1 fat
Meal replacement bar	1 bar (2 oz)	2 carbohydrates + 1 fat
Meal replacement shake, reduced kcalorie	1 can (10–11 oz)	1 1/2 carbohydrates + 0–1 fat
Trail mix		
candy/nut-based	1 oz	1 carbohydrate + 2 fats
dried fruit-based	1 oz	1 carbohydrate + 1 fat

TABLE G-6 Nonstarchy Vegetables

The Nonstarchy Vegetables list includes vegetables that have few grams of carbohydrates or kcalories; starchy vegetables are found on the Starch list. 1 nonstarchy vegetable choice = 5 g carbohydrate, 2 g protein, 0 g fat, and 25 kcal.
Note: In general, one nonstarchy vegetable choice is 1/2 cup cooked vegetables or vegetable juice or 1 cup raw vegetables. Count 3 cups of raw vegetables or 1 1/2 cups of cooked vegetables as one carbohydrate choice.

Nonstarchy Vegetables[a]

Amaranth or Chinese spinach
Artichoke
Artichoke hearts
Asparagus
Baby corn
Bamboo shoots
Beans (green, wax, Italian)
Bean sprouts
Beets
Borscht
Broccoli
Brussels sprouts
Cabbage (green, bok choy, Chinese)
Carrots
Cauliflower
Celery
Chayote
Coleslaw, packaged, no dressing
Cucumber
Eggplant
Gourds (bitter, bottle, luffa, bitter melon)
Green onions or scallions
Greens (collard, kale, mustard, turnip)
Hearts of palm
Jicama
Kohlrabi
Leeks
Mixed vegetables (without corn, peas, or pasta)
Mung bean sprouts
Mushrooms, all kinds, fresh
Okra
Onions
Oriental radish or daikon
Pea pods
Peppers (all varieties)
Radishes
Rutabaga
Sauerkraut
Soybean sprouts
Spinach
Squash (summer, crookneck, zucchini)
Sugar pea snaps
Swiss chard
Tomato
Tomatoes, canned
Tomato sauce
Tomato/vegetable juice
Turnips
Water chestnuts
Yard-long beans

KEY

= More than 3 grams of dietary fiber per serving.
= 480 milligrams or more of sodium per serving.

[a]Salad greens (like chicory, endive, escarole, lettuce, romaine, spinach, arugula, radicchio, watercress) are on the Free Foods list.

TABLE G-7 Meat and Meat Substitutes

The Meat and Meat Substitutes list groups foods based on the amount of fat they have (lean meat, medium-fat meat, high-fat meat, and plant-based proteins).

Lean Meats and Meat Substitutes

1 lean meat choice = 0 g carbohydrate, 7 g protein, 0–3 g fat, and 100 kcal.

Food	Amount
Beef: Select or Choice grades trimmed of fat: ground round, roast (chuck, rib, rump), round, sirloin, steak (cubed, flank, porterhouse, T-bone), tenderloin	1 oz
Beef jerky	1 oz
Cheeses with 3 grams of fat or less per oz	1 oz
Cottage cheese	1/4 cup
Egg substitutes, plain	1/4 cup
Egg whites	2
Fish, fresh or frozen, plain: catfish, cod, flounder, haddock, halibut, orange roughy, salmon, tilapia, trout, tuna	1 oz
Fish, smoked: herring or salmon (lox)	1 oz
Game: buffalo, ostrich, rabbit, venison	1 oz
Hot dog with 3 grams of fat or less per oz (8 dogs per 14 oz package) *Note: May be high in carbohydrate.*	1
Lamb: chop, leg, or roast	1 oz
Organ meats: heart, kidney, liver *Note: May be high in cholesterol.*	1 oz
Oysters, fresh or frozen	6 medium
Pork, lean	
Canadian bacon	1 oz
rib or loin chop/roast, ham, tenderloin	1 oz
Poultry, without skin: Cornish hen, chicken, domestic duck or goose (well-drained of fat), turkey	1 oz
Processed sandwich meats with 3 grams of fat or less per oz: chipped beef, deli thin-sliced meats, turkey ham, turkey kielbasa, turkey pastrami	1 oz
Salmon, canned	1 oz
Sardines, canned	2 medium
Sausage with 3 grams of fat or less per oz	1 oz
Shellfish: clams, crab, imitation shellfish, lobster, scallops, shrimp	1 oz
Tuna, canned in water or oil, drained	1 oz
Veal, lean chop, roast	1 oz

Medium-Fat Meat and Meat Substitutes

1 medium-fat meat choice = 0 g carbohydrate, 7 g protein, 4–7 g fat, and 130 kcal.

Food	Amount
Beef: corned beef, ground beef, meatloaf, Prime grades trimmed of fat (prime rib), short ribs, tongue	1 oz
Cheeses with 4–7 grams of fat per oz: feta, mozzarella, pasteurized processed cheese spread, reduced-fat cheeses, string	1 oz
Egg *Note: High in cholesterol, so limit to 3 per week.*	1
Fish, any fried product	1 oz
Lamb: ground, rib roast	1 oz
Pork: cutlet, shoulder roast	1 oz
Poultry: chicken with skin; dove, pheasant, wild duck, or goose; fried chicken; ground turkey	1 oz
Ricotta cheese	2 oz or 1/4 cup
Sausage with 4–7 grams of fat per oz	1 oz
Veal, cutlet (no breading)	1 oz

High-Fat Meat and Meat Substitutes

1 high-fat meat choice = 0 g carbohydrate, 7 g protein, 8+ g fat, and 150 kcal. These foods are high in saturated fat, cholesterol, and kcalories and may raise blood cholesterol levels if eaten on a regular basis. Try to eat 3 or fewer servings from this group per week.

Food	Amount
Bacon	
pork	2 slices (16 slices per lb or 1 oz each, before cooking)
turkey	3 slices (1/2 oz each before cooking)
Cheese, regular: American, bleu, brie, cheddar, hard goat, Monterey jack, queso, and Swiss	1 oz
Hot dog: beef, pork, or combination (10 per lb-sized package)	1
Hot dog: turkey or chicken (10 per lb-sized package)	1
Pork: ground, sausage, spareribs	1 oz
Processed sandwich meats with 8 grams of fat or more per oz: bologna, pastrami, hard salami	1 oz
Sausage with 8 grams fat or more per oz: bratwurst, chorizo, Italian, knockwurst, Polish, smoked, summer	1 oz

(continued)

TABLE G-7 Meats and Meat Substitutes—*continued*

Plant-Based Proteins

1 plant-based protein choice = variable grams carbohydrate, 7g protein, variable grams fat, and variable kcalories.
Because carbohydrate content varies among plant-based proteins, you should read the food label.

Food	Serving Size	Count as
"Bacon" strips, soy-based	3 strips	1 medium-fat meat
Baked beans	1/3 cup	1 starch + 1 lean meat
Beans, cooked: black, garbanzo, kidney, lima, navy, pinto, white[a]	1/2 cup	1 starch + 1 lean meat
"Beef" or "sausage" crumbles, soy-based	2 oz	1/2 carbohydrate + 1 lean meat
"Chicken" nuggets, soy-based	2 nuggets (1 1/2 oz)	1/2 carbohydrate + 1 medium-fat meat
Edamame	1/2 cup	1/2 carbohydrate + 1 lean meat
Falafel (spiced chickpea and wheat patties)	3 patties (about 2 inches across)	1 carbohydrate + 1 high-fat meat
Hog dog, soy-based	1 (1 1/2 oz)	1/2 carbohydrate + 1 lean meat
Hummus	1/3 cup	1 carbohydrate + 1 high-fat meat
Lentils, brown, green, or yellow	1/2 cup	1 carbohydrate + 1 lean meat
Meatless burger, soy-based	3 oz	1/2 carbohydrate + 2 lean meats
Meatless burger, vegetable- and starch-based	1 patty (about 2 1/2 oz)	1 carbohydrate + 2 lean meats
Nut spreads: almond butter, cashew butter, peanut butter, soy nut butter	1 Tbsp	1 high-fat meat
Peas, cooked: black-eyed and split peas	1/2 cup	1 starch + 1 lean meat
Refried beans, canned	1/2 cup	1 starch + 1 lean meat
"Sausage" patties, soy-based	1 (1 1/2 oz)	1 medium-fat meat
Soy nuts, unsalted	3/4 oz	1/2 carbohydrate + 1 medium-fat meat
Tempeh	1/4 cup	1 medium-fat meat
Tofu	4 oz (1/2 cup)	1 medium-fat meat
Tofu, light	4 oz (1/2 cup)	1 lean meat

KEY

= More than 3 grams of dietary fiber per serving.
= Extra fat, or prepared with added fat. (Add an additional fat choice to this food.)
= 480 milligrams or more of sodium per serving (based on the sodium content of a typical 3-oz serving of meat, unless 1 or 2 oz is the normal serving size).

[a]Beans, peas, and lentils are also found on the Starch list; nut butters in smaller amounts are found in the Fats list.

TABLE G-8 Fats

Fats and oils have mixtures of unsaturated (polyunsaturated and monounsaturated) and saturated fats. Foods on the Fats list are grouped together based on the major type of fat they contain. 1 fat choice = 0 g carbohydrate, 0 g protein, 5 g fat, and 45 kcal.
Note: In general, one fat exchange is 1 teaspoon of regular margarine, vegetable oil, or butter; 1 tablespoon of regular salad dressing.

When used in large amounts, bacon and peanut butter are counted as high-fat meat choices (see Meat and Meat Substitutes list). Fat-free salad dressings are found on the Sweets, Desserts, and Other Carbohydrates list. Fat-free products such as margarines, salad dressings, mayonnaise, sour cream, and cream cheese are found on the Free Foods list.

Monounsaturated Fats

Food	Serving Size
Avocado, medium	2 Tbsp (1 oz)
Nut butters (*trans* fat-free): almond butter, cashew butter, peanut butter (smooth or crunchy)	1 1/2 tsp
Nuts	
almonds	6 nuts
Brazil	2 nuts
cashews	6 nuts
filberts (hazelnuts)	5 nuts
macadamia	3 nuts
mixed (50% peanuts)	6 nuts
peanuts	10 nuts
pecans	4 halves
pistachios	16 nuts
Oil: canola, olive, peanut	1 tsp
Olives	
black (ripe)	8 large
green, stuffed	10 large

Polyunsaturated Fats

Food	Serving Size
Margarine: lower-fat spread (30%–50% vegetable oil, *trans* fat-free)	1 Tbsp
Margarine: stick, tub (*trans* fat-free) or squeeze (*trans* fat-free)	1 tsp
Mayonnaise	
reduced-fat	1 Tbsp
regular	1 tsp
Mayonnaise-style salad dressing	
reduced-fat	1 Tbsp
regular	2 tsp
Nuts	
Pignolia (pine nuts)	1 Tbsp
walnuts, English	4 halves
Oil: corn, cottonseed, flaxseed, grape seed, safflower, soybean, sunflower	1 tsp
Oil: made from soybean and canola oil—Enova	1 tsp
Plant stanol esters	
light	1 Tbsp
regular	2 tsp

Polyunsaturated Fats

Food	Serving Size
Salad dressing	
reduced-fat	2 Tbsp
Note: May be high in carbohydrate.	
regular	1 Tbsp
Seeds	
flaxseed, whole	1 Tbsp
pumpkin, sunflower	1 Tbsp
sesame seeds	1 Tbsp
Tahini or sesame paste	2 tsp

Saturated Fats

Food	Serving Size
Bacon, cooked, regular or turkey	1 slice
Butter	
reduced-fat	1 Tbsp
stick	1 tsp
whipped	2 tsp
Butter blends made with oil	
reduced-fat or light	1 Tbsp
regular	1 1/2 tsp
Chitterlings, boiled	2 Tbsp (1/2 oz)
Coconut, sweetened, shredded	2 Tbsp
Coconut milk	
light	1/3 cup
regular	1 1/2 Tbsp
Cream	
half and half	2 Tbsp
heavy	1 Tbsp
light	1 1/2 Tbsp
whipped	2 Tbsp
whipped, pressurized	1/4 cup
Cream cheese	
reduced-fat	1 1/2 Tbsp (3/4 oz)
regular	1 Tbsp (1/2 oz)
Lard	1 tsp
Oil: coconut, palm, palm kernel	1 tsp
Salt pork	1/4 oz
Shortening, solid	1 tsp
Sour cream	
reduced-fat or light	3 Tbsp
regular	2 Tbsp

KEY

= 480 milligrams or more of sodium per serving.

TABLE G-9 Free Foods

A "free" food is any food or drink choice that has less than 20 kcalories and 5 grams or less of carbohydrate per serving.

- Most foods on this list should be limited to 3 servings (as listed here) per day. Spread out the servings throughout the day. If you eat all 3 servings at once, it could raise your blood glucose level.
- Food and drink choices listed here without a serving size can be eaten whenever you like.

Low Carbohydrate Foods

Food	Serving Size
Cabbage, raw	1/2 cup
Candy, hard (regular or sugar-free)	1 piece
Carrots, cauliflower, or green beans, cooked	1/4 cup
Cranberries, sweetened with sugar substitute	1/2 cup
Cucumber, sliced	1/2 cup
Gelatin	
dessert, sugar-free	
unflavored	
Gum	
Jam or jelly, light or no sugar added	2 tsp
Rhubarb, sweetened with sugar substitute	1/2 cup
Salad greens	
Sugar substitutes (artificial sweeteners)	
Syrup, sugar-free	2 Tbsp

Modified Fat Foods with Carbohydrate

Food	Serving Size
Cream cheese, fat-free	1 Tbsp (1/2 oz)
Creamers	
nondairy, liquid	1 Tbsp
nondairy, powdered	2 tsp
Margarine spread	
fat-free	1 Tbsp
reduced-fat	1 tsp
Mayonnaise	
fat-free	1 Tbsp
reduced-fat	1 tsp
Mayonnaise-style salad dressing	
fat-free	1 Tbsp
reduced-fat	1 tsp
Salad dressing	
fat-free or low-fat	1 Tbsp
fat-free, Italian	2 Tbsp
Sour cream, fat-free or reduced-fat	1 Tbsp
Whipped topping	
light or fat-free	2 Tbsp
regular	1 Tbsp

Condiments

Food	Serving Size
Barbecue sauce	2 tsp
Catsup (ketchup)	1 Tbsp
Honey mustard	1 Tbsp
Horseradish	

Condiments

Food	Serving Size
Lemon juice	
Miso	1 1/2 tsp
Mustard	
Parmesan cheese, freshly grated	1 Tbsp
Pickle relish	1 Tbsp
Pickles	
dill	1 1/2 medium
sweet, bread and butter	2 slices
sweet, gherkin	3/4 oz
Salsa	1/4 cup
Soy sauce, light or regular	1 Tbsp
Sweet and sour sauce	2 tsp
Sweet chili sauce	2 tsp
Taco sauce	1 Tbsp
Vinegar	
Yogurt, any type	2 Tbsp

Drinks/Mixes

Any food on the list—without a serving size listed—can be consumed in any moderate amount.

- Bouillon, broth, consommé
- Bouillon or broth, low-sodium
- Carbonated or mineral water
- Club soda
- Cocoa powder, unsweetened (1 Tbsp)
- Coffee, unsweetened or with sugar substitute
- Diet soft drinks, sugar-free
- Drink mixes, sugar-free
- Tea, unsweetened or with sugar substitute
- Tonic water, diet
- Water
- Water, flavored, carbohydrate free

Seasonings

Any food on this list can be consumed in any moderate amount.

- Flavoring extracts (for example, vanilla, almond, peppermint)
- Garlic
- Herbs, fresh or dried
- Nonstick cooking spray
- Pimento
- Spices
- Hot pepper sauce
- Wine, used in cooking
- Worcestershire sauce

KEY

= 480 milligrams or more of sodium per serving.

TABLE G-10 Combination Foods

Many foods are eaten in various combinations, such as casseroles. Because "combination" foods do not fit into any one choice list, this list of choices provides some typical combination foods.

Entrees

Food	Serving Size	Count as
Casserole type (tuna noodle, lasagna, spaghetti with meatballs, chili with beans, macaroni and cheese)	1 cup (8 oz)	2 carbohydrates + 2 medium-fat meats
Stews (beef/other meats and vegetables)	1 cup (8 oz)	1 carbohydrate + 1 medium-fat meat + 0–3 fats
Tuna salad or chicken salad	1/2 cup (3 1/2 oz)	1/2 carbohydrate + 2 lean meats + 1 fat

Frozen Meals/Entrees

Food	Serving Size	Count as
Burrito (beef and bean)	1 (5 oz)	3 carbohydrates + 1 lean meat + 2 fats
Dinner-type meal	generally 14–17 oz	3 carbohydrates + 3 medium-fat meats + 3 fats
Entrée or meal with less than 340 kcalories	about 8–11 oz	2–3 carbohydrates + 1–2 lean meats
Pizza		
cheese/vegetarian, thin crust	1/4 of a 12 inch (4 1/2–5 oz)	2 carbohydrates + 2 medium-fat meats
meat topping, thin crust	1/4 of a 12 inch (5 oz)	2 carbohydrates + 2 medium-fat meats + 1 1/2 fats
Pocket sandwich	1 (4 1/2 oz)	3 carbohydrates + 1 lean meat + 1–2 fats
Pot pie	1 (7 oz)	2 1/2 carbohydrates + 1 medium-fat meat + 3 fats

Salads (Deli-Style)

Food	Serving Size	Count as
Coleslaw	1/2 cup	1 carbohydrate + 1 1/2 fats
Macaroni/pasta salad	1/2 cup	2 carbohydrates + 3 fats
Potato salad	1/2 cup	1 1/2–2 carbohydrates + 1–2 fats

Soups

Food	Serving Size	Count as
Bean, lentil, or split pea	1 cup	1 carbohydrate + 1 lean meat
Chowder (made with milk)	1 cup (8 oz)	1 carbohydrate + 1 lean meat + 1 1/2 fats
Cream (made with water)	1 cup (8 oz)	1 carbohydrate + 1 fat
Instant	6 oz prepared	1 carbohydrate
with beans or lentils	8 oz prepared	2 1/2 carbohydrates + 1 lean meat
Miso soup	1 cup	1/2 carbohydrate + 1 fat
Oriental noodle	1 cup	2 carbohydrates + 2 fats
Rice (congee)	1 cup	1 carbohydrate
Tomato (made with water)	1 cup (8 oz)	1 carbohydrate
Vegetable beef, chicken noodle, or other broth-type	1 cup (8 oz)	1 carbohydrate

KEY

= More than 3 grams of dietary fiber per serving.
= Extra fat, or prepared with added fat.
= 600 milligrams or more of sodium per serving (for combination food main dishes/meals).

TABLE G-11 Fast Foods

The choices in the Fast Foods list are not specific fast-food meals or items, but are estimates based on popular foods. Ask the restaurant or check its website for nutrition information about your favorite fast foods.

Breakfast Sandwiches

Food	Serving Size	Count as
Egg, cheese, meat, English muffin	1 sandwich	2 carbohydrates + 2 medium-fat meats
Sausage biscuit sandwich	1 sandwich	2 carbohydrates + 2 high-fat meats + 3 1/2 fats

Main Dishes/Entrees

Food	Serving Size	Count as
Burrito (beef and beans)	1 (about 8 oz)	3 carbohydrates + 3 medium-fat meats + 3 fats
Chicken breast, breaded and fried	1 (about 5 oz)	1 carbohydrate + 4 medium-fat meats
Chicken drumstick, breaded and fried	1 (about 2 oz)	2 medium-fat meats
Chicken nuggets	6 (about 3 1/2 oz)	1 carbohydrate + 2 medium-fat meats + 1 fat
Chicken thigh, breaded and fried	1 (about 4 oz)	1/2 carbohydrate + 3 medium-fat meats + 1 1/2 fats
Chicken wings, hot	6 (5 oz)	5 medium-fat meats + 1 1/2 fats

Oriental

Food	Serving Size	Count as
Beef/chicken/shrimp with vegetables in sauce	1 cup (about 5 oz)	1 carbohydrate + 1 lean meat + 1 fat
Egg roll, meat	1 (about 3 oz)	1 carbohydrate + 1 lean meat + 1 fat
Fried rice, meatless	1/2 cup	1 1/2 carbohydrates + 1 1/2 fats
Meat and sweet sauce (orange chicken)	1 cup	3 carbohydrates + 3 medium-fat meats + 2 fats
Noodles and vegetables in sauce (chow mein, lo mein)	1 cup	2 carbohydrates + 1 fat

Pizza

Food	Serving Size	Count as
Pizza		
cheese, pepperoni, regular crust	1/8 of a 14 inch (about 4 oz)	2 1/2 carbohydrates + 1 medium-fat meat + 1 1/2 fats
cheese/vegetarian, thin crust	1/4 of a 12 inch (about 6 oz)	2 1/2 carbohydrates + 2 medium-fat meats + 1 1/2 fats

Sandwiches

Food	Serving Size	Count as
Chicken sandwich, grilled	1	3 carbohydrates + 4 lean meats
Chicken sandwich, crispy	1	3 1/2 carbohydrates + 3 medium-fat meats + 1 fat
Fish sandwich with tartar sauce	1	2 1/2 carbohydrates + 2 medium-fat meats + 2 fats
Hamburger		
large with cheese	1	2 1/2 carbohydrates + 4 medium-fat meats + 1 fat
regular	1	2 carbohydrates + 1 medium-fat meat + 1 fat
Hot dog with bun	1	1 carbohydrate + 1 high-fat meat + 1 fat
Submarine sandwich		
less than 6 grams fat	6-inch sub	3 carbohydrates + 2 lean meats
regular	6-inch sub	3 1/2 carbohydrates + 2 medium-fat meats + 1 fat
Taco, hard or soft shell (meat and cheese)	1 small	1 carbohydrate + 1 medium-fat meat + 1 1/2 fats

KEY

= More than 3 grams of dietary fiber per serving.
= Extra fat, or prepared with added fat.
= 600 milligrams or more of sodium per serving (for fast-food main dishes/meals).

(continued)

TABLE G-11 Fast Foods—*continued*

Salads

Food	Serving Size	Count as
Salad, main dish (grilled chicken type, no dressing or croutons)		1 carbohydrate + 4 lean meats
Salad, side, no dressing or cheese	Small (about 5 oz)	1 vegetable

Sides/Appetizers

Food	Serving Size	Count as
French fries, restaurant style	small	3 carbohydrates + 3 fats
	medium	4 carbohydrates + 4 fats
	large	5 carbohydrates + 6 fats
Nachos with cheese	small (about $4^1/_2$ oz)	$2^1/_2$ carbohydrates + 4 fats
Onion rings	1 serving (about 3 oz)	$2^1/_2$ carbohydrates + 3 fats

Desserts

Food	Serving Size	Count as
Milkshake, any flavor	12 oz	6 carbohydrates + 2 fats
Soft-serve ice cream cone	1 small	$2^1/_2$ carbohydrates + 1 fat

KEY

= More than 3 grams of dietary fiber per serving.
= Extra fat, or prepared with added fat.
= 600 milligrams or more of sodium per serving (for fast-food main dishes/meals).

TABLE G-12 Alcohol

1 alcohol equivalent = variable grams carbohydrate, 0 g protein, 0 g fat, and 100 kcal.
Note: In general, one alcohol choice ($^1/_2$ oz absolute alcohol) has about 100 kcalories. For those who choose to drink alcohol, guidelines suggest limiting alcohol intake to 1 drink or less per day for women, and 2 drinks or less per day for men. To reduce your risk of low blood glucose (hypoglycemia), especially if you take insulin or a diabetes pill that increases insulin, always drink alcohol with food. While alcohol, by itself, does not directly affect blood glucose, be aware of the carbohydrate (for example, in mixed drinks, beer, and wine) that may raise your blood glucose.

Alcoholic Beverage	Serving Size	Count as
Beer		
light (4.2%)	12 fl oz	1 alcohol equivalent + $^1/_2$ carbohydrate
regular (4.9%)	12 fl oz	1 alcohol equivalent + 1 carbohydrate
Distilled spirits: vodka, rum, gin, whiskey		
80 or 86 proof	$1^1/_2$ fl oz	1 alcohol equivalent
Liqueur, coffee (53 proof)	1 fl oz	1 alcohol equivalent + 1 carbohydrate
Sake	1 fl oz	$^1/_2$ alcohol equivalent
Wine		
dessert (sherry)	$3^1/_2$ fl oz	1 alcohol equivalent + 1 carbohydrate
dry, red or white (10%)	5 fl oz	1 alcohol equivalent

CONTENTS

Table of Food Composition

Table of Food Composition

This edition of the table of food composition includes a wide variety of foods. It is updated with each edition to reflect current nutrient data for foods, to remove outdated foods, and to add foods that are new to the marketplace.* The nutrient database for this appendix is compiled from a variety of sources, including the USDA Standard Release database and manufacturers' data. The USDA database provides data for a wider variety of foods and nutrients than other sources. Because laboratory analysis for each nutrient can be quite costly, manufacturers tend to provide data only for those nutrients mandated on food labels. Consequently, data for their foods are often incomplete; any missing information on this table is designated as a dash. Keep in mind that a dash means only that the information is unknown and should not be interpreted as a zero. A zero means that the nutrient is not present in the food.

Whenever using nutrient data, remember that many factors influence the nutrient contents of foods. These factors include the mineral content of the soil, the diet fed to the animal or the fertilizer used on the plant, the season of harvest, the method of processing, the length and method of storage, the method of cooking, the method of analysis, and the moisture content of the sample analyzed. With so many influencing factors, users should view nutrient data as a close approximation of the actual amount.

For updates, corrections, and a list of more than 8000 foods and codes found in the diet analysis software that accompanies this text, visit www.thomsonedu.com/nutrition and click on Diet Analysis Plus.

- ***Fats*** Total fats, as well as the breakdown of total fats to saturated, monounsaturated, polyunsaturated, and *trans* fats, are listed in the table. The fatty acids seldom add up to the total in part due to rounding but also because values are derived from a variety of laboratories.
- ***Trans Fats*** *Trans* fat data has been listed in the table. Because food manufacturers have only been required to report *trans* fats on food labels since January 2006, much of the data is incomplete. Missing *trans* fat data is designated with a dash. As additional *trans* fat data becomes available, the table will be updated.
- ***Vitamin A and Vitamin E*** In keeping with the 2001 RDA for vitamin A, this appendix presents data for vitamin A in micrograms (μg) RAE. Similarly, because the 2000 RDA for vitamin E is based only on the alpha-tocopherol form of vitamin E, this appendix reports vitamin E data in milligrams (mg) alpha-tocopherol, listed on the table as Vit E (mg α).
- ***Bioavailability*** Keep in mind that the availability of nutrients from foods depends not only on the quantity provided by a food, but also on the amount absorbed and used by the body—the bioavailability. The bioavailability of folate from fortified foods, for example, is greater than from naturally occurring sources. Similarly, the body can make niacin from the amino acid tryptophan, but niacin values in this table (and most databases) report preformed niacin only. Chapter 10 provides conversion factors and additional details.
- ***Using the Table*** The foods and beverages in this table are organized into several categories, which are listed at the head of each right-hand page. Page numbers are provided, and each group is color-coded to make it easier to find individual foods.
- ***Caffeine Sources*** Caffeine occurs in several plants, including the familiar coffee bean, the tea leaf, and the cocoa bean from which chocolate is made.

*This food composition table has been prepared by Wadsworth Publishing Company. The nutritional data are supplied by Axxya Systems.

Most human societies use caffeine regularly, most often in beverages, for its stimulant effect and flavor. Caffeine contents of beverages vary depending on the plants they are made from, the climates and soils where the plants are grown, the grind or cut size, the method and duration of brewing, and the amounts served. The accompanying table shows that, in general, a cup of coffee contains the most caffeine; a cup of tea, less than half as much; and cocoa or chocolate, less still. As for cola beverages, they are made from kola nuts, which contain caffeine, but most of their caffeine is added, using the purified compound obtained from decaffeinated coffee beans. The FDA lists caffeine as a multipurpose GRAS substance ◆ that may be added to foods and beverages. Drug manufacturers use caffeine in many products.

◆ Reminder: A GRAS substance is one that is "generally recognized as safe."

TABLE Caffeine Content of Selected Beverages, Foods, and Medications

Beverages and Foods	Serving Size	Average (mg)
Coffee		
Brewed	8 oz	95
Decaffeinated	8 oz	2
Instant	8 oz	64
Tea		
Brewed, green	8 oz	30
Brewed, herbal	8 oz	0
Brewed, leaf or bag	8 oz	47
Instant	8 oz	26
Lipton Brisk iced tea	12 oz	7
Nestea Cool iced tea	12 oz	12
Snapple iced tea (all flavors)	16 oz	42
Soft drinks		
A & W Creme Soda	12 oz	29
Barq's Root Beer	12 oz	18
Coca-Cola	12 oz	30
Dr. Pepper, Mr. Pibb, Sunkist Orange	12 oz	36
A&W Root Beer, club soda, Fresca, ginger ale, 7-Up, Sierra Mist, Sprite, Squirt, tonic water, caffeine-free soft drinks	12 oz	0
Mello Yello	12 oz	51
Mountain Dew	12 oz	45
Pepsi	12 oz	32
Energy drinks		
Amp	8.4 oz	70
Aqua Blast	.5 L	90
Aqua Java	.5 L	55
E Maxx	8.4 oz	74
Java Water	.5 L	125
KMX	8.4 oz	33
Krank	.5 L	100
Red Bull	8.3 oz	67
Red Devil	8.4 oz	42
Sobe Adrenaline Rush	8.3 oz	77
Sobe No Fear	16 oz	141
Water Joe	.5 L	65

Beverages and Foods	Serving Size	Average (mg)
Other beverages		
Chocolate milk or hot cocoa	8 oz	5
Starbucks Frappuccino Mocha	9.5 oz	72
Starbucks Frappuccino Vanilla	9.5 oz	64
Yoohoo chocolate drink	9 oz	3
Candies		
Baker's chocolate	1 oz	26
Dark chocolate covered coffee beans	1 oz	235
Dark chocolate, semisweet	1 oz	18
Milk chocolate	1 oz	6
Milk chocolate covered coffee beans	1 oz	224
White chocolate	1 oz	0
Foods		
Frozen yogurt, Ben & Jerry's coffee fudge	1 cup	85
Frozen yogurt, Häagen-Dazs coffee	1 cup	40
Ice cream, Starbucks coffee	1 cup	50
Ice cream, Starbucks Frappuccino bar	1 bar	15
Yogurt, Dannon coffee flavored	1 cup	45
Drugs[a]	**Serving Size**	**Average (mg)**
Cold remedies		
Coryban-D, Dristan	1 tablet	30
Diuretics		
Aqua-Ban	1 tablet	100
Pre-Mens Forte	1 tablet	100
Pain relievers		
Anacin, BC Fast Pain Reliever	1 tablet	32
Excedrin, Midol, Midol Max Strength	1 tablet	65
Stimulants		
Awake, NoDoz	1 tablet	100
Awake Maximum Strength, Caffedrine, NoDoz Maximum Strength, Stay Awake, Vivarin	1 tablet	200
Weight-control aids		
Dexatrim	1 tablet	200

[a]A pharmacologically active dose of caffiene is defined as 200 milligrams.

NOTE: The FDA suggests a maximum of 65 milligrams per 12-ounce cola beverage but does not regulate the caffeine contents of other beverages. Because products change, contact the manufacturer for an update on products you use regularly.

TABLE H–1

Food Composition (DA+ code is for Wadsworth Diet Analysis program) (For purposes of calculations, use "0" for t, <1, <.1, <.01, etc.)

DA + Code	Food Description	Quantity	Measure	Wt (g)	H_2O (g)	Ener (kcal)	Prot (g)	Carb (g)	Fiber (g)	Fat (g)	Fat Breakdown (g) Sat	Mono	Poly	*Trans*
	VEGETABLES, LEGUMES —Continued													
	Bamboo shoots													
1048	Boiled, drained	½	cup(s)	60	58	7	1	1	1	<1	0.03	0.00	0.06	—
1049	Canned, drained	½	cup(s)	65	62	12	1	2	1	<1	0.06	0.01	0.12	—
	Beans													
1801	Adzuki beans, boiled	½	cup(s)	115	76	147	9	28	8	<1	0.04	—	—	—
511	Baked beans w/franks, canned	½	cup(s)	129	89	182	9	20	9	8	3.02	3.64	1.07	—
512	Baked beans w/pork in tomato sauce, canned	½	cup(s)	127	92	124	7	25	6	1	0.50	0.56	0.17	—
513	Baked beans w/pork in sweet sauce, canned	½	cup(s)	127	89	140	7	27	7	2	0.71	0.80	0.24	0
1805	Black beans, boiled	½	cup(s)	86	57	114	8	20	7	<1	0.12	0.04	0.20	—
14597	Chickpeas, garbanzo beans, or bengal gram, boiled	½	cup(s)	82	49	134	7	22	6	2	0.22	0.48	0.95	—
569	Fordhook lima beans, frozen, boiled, drained	½	cup(s)	85	62	88	5	16	5	<1	0.07	0.02	0.14	—
1806	French beans, boiled	½	cup(s)	89	59	114	6	21	8	1	0.07	0.05	0.40	—
2773	Great northern beans, boiled	½	cup(s)	89	61	104	7	19	6	<1	0.12	0.02	0.17	—
2736	Hyacinth beans, boiled, drained	½	cup(s)	44	38	22	1	4	0	<1	0.05	0.06	0.00	—
515	Lima beans, boiled, drained	½	cup(s)	85	57	105	6	20	5	<1	0.06	0.02	0.13	—
570	Lima beans, baby, frozen, boiled, drained	½	cup(s)	90	65	95	6	18	5	<1	0.06	0.02	0.13	—
579	Mung beans, sprouted, boiled, drained	½	cup(s)	62	62	13	1	3	<1	<.1	0.02	0.00	0.02	—
510	Navy beans, boiled	½	cup(s)	91	57	129	8	24	6	1	0.13	0.05	0.22	0
32816	Pinto beans, boiled, drained, no salt added	½	cup(s)	114	106	25	2	5	0	<1	0.04	0.03	0.21	—
1052	Pinto beans, frozen, boiled, drained	½	cup(s)	47	27	76	4	15	4	<1	0.03	0.02	0.13	—
514	Red kidney beans, canned	½	cup(s)	128	99	109	7	20	8	<1	0.06	0.03	0.24	—
1810	Refried beans, canned	½	cup(s)	127	96	119	7	20	7	2	0.60	0.71	0.19	—
1053	Shell beans, canned	½	cup(s)	123	111	37	2	8	4	<1	0.03	0.02	0.13	—
1670	Soybeans, boiled	½	cup(s)	86	54	149	14	9	5	8	1.12	1.70	4.36	—
1108	Soybeans, green, boiled, drained	½	cup(s)	90	62	127	11	10	4	6	0.67	1.09	2.71	—
1807	White beans, small, boiled	½	cup(s)	90	57	127	8	23	9	1	0.15	0.05	0.25	—
574	Green string beans, canned, fat added in cooking	½	cup(s)	93	63	41	1	4	2	3	0.51	1.23	0.75	—
575	Yellow snap, string or wax beans, boiled, drained	½	cup(s)	62	56	22	1	5	2	<1	0.04	0.00	0.09	—
576	Yellow snap, string or wax beans, frozen, boiled, drained	½	cup(s)	68	62	19	1	4	2	<1	0.02	0.00	0.05	—
	Beets													
580	Whole, boiled, drained	2	item(s)	100	87	44	2	10	2	<1	0.03	0.04	0.06	—
581	Sliced, boiled, drained	½	cup(s)	85	74	37	1	8	2	<1	0.02	0.03	0.05	—
583	Sliced, canned, drained	½	cup(s)	85	77	26	1	6	1	<1	0.02	0.02	0.04	—
2730	Pickled, canned with liquid	½	cup(s)	114	93	74	1	18	3	<1	0.01	0.02	0.03	—
584	Beet greens, boiled, drained	½	cup(s)	72	64	19	2	4	2	<1	0.02	0.03	0.05	—

WHO: Nutrition Recommendations Canada: Guidelines and Meal Planning

This appendix presents nutrition recommendations from the World Health Organization (WHO) and details for Canadians on the *Eating Well with Canada's Food Guide* and the *Beyond the Basics* meal planning system.

CONTENTS

Nutrition Recommendations from WHO
Eating Well with Canada's Food Guide
Canada's Meal Planning for Healthy Eating

Nutrition Recommendations from WHO

The World Health Organization (WHO) has assessed the relationships between diet and the development of chronic diseases. Its recommendations include:

- Energy: sufficient to support growth, physical activity, and a healthy body weight (BMI between 18.5 and 24.9) and to avoid weight gain greater than 11 pounds (5 kilograms) during adult life
- Total fat: 15 to 30 percent of total energy
- Saturated fatty acids: <10 percent of total energy
- Polyunsaturated fatty acids: 6 to 10 percent of total energy
- Omega-6 polyunsaturated fatty acids: 5 to 8 percent of total energy
- Omega-3 polyunsaturated fatty acids: 1 to 2 percent of total energy
- *Trans*-fatty acids: <1 percent of total energy
- Total carbohydrate: 55 to 75 percent of total energy
- Sugars: <10 percent of total energy
- Protein: 10 to 15 percent of total energy
- Cholesterol: <300 mg per day
- Salt (sodium): <5 g salt per day (<2 g sodium per day), appropriately iodized
- Fruits and vegetables: ≥400 g per day (about 1 pound)
- Total dietary fiber: >25 g per day from foods
- Physical activity: one hour of moderate-intensity activity, such as walking, on most days of the week

Eating Well with Canada's Food Guide

Figure I-1 presents the 2007 *Eating Well with Canada's Food Guide,* which interprets Canada's *Guidelines for Healthy Eating* (see Table 2-2 on p. 40) for consumers and recommends a range of servings to consume daily from each of the four food groups. Additional publications, which are available from Health Canada ◆ through its website, provide many more details.

◆ Search for "Canada's food guide" at Health Canada: **www.hc-sc.gc.ca**

FIGURE I-1 *Eating Well with Canada's Food Guide*

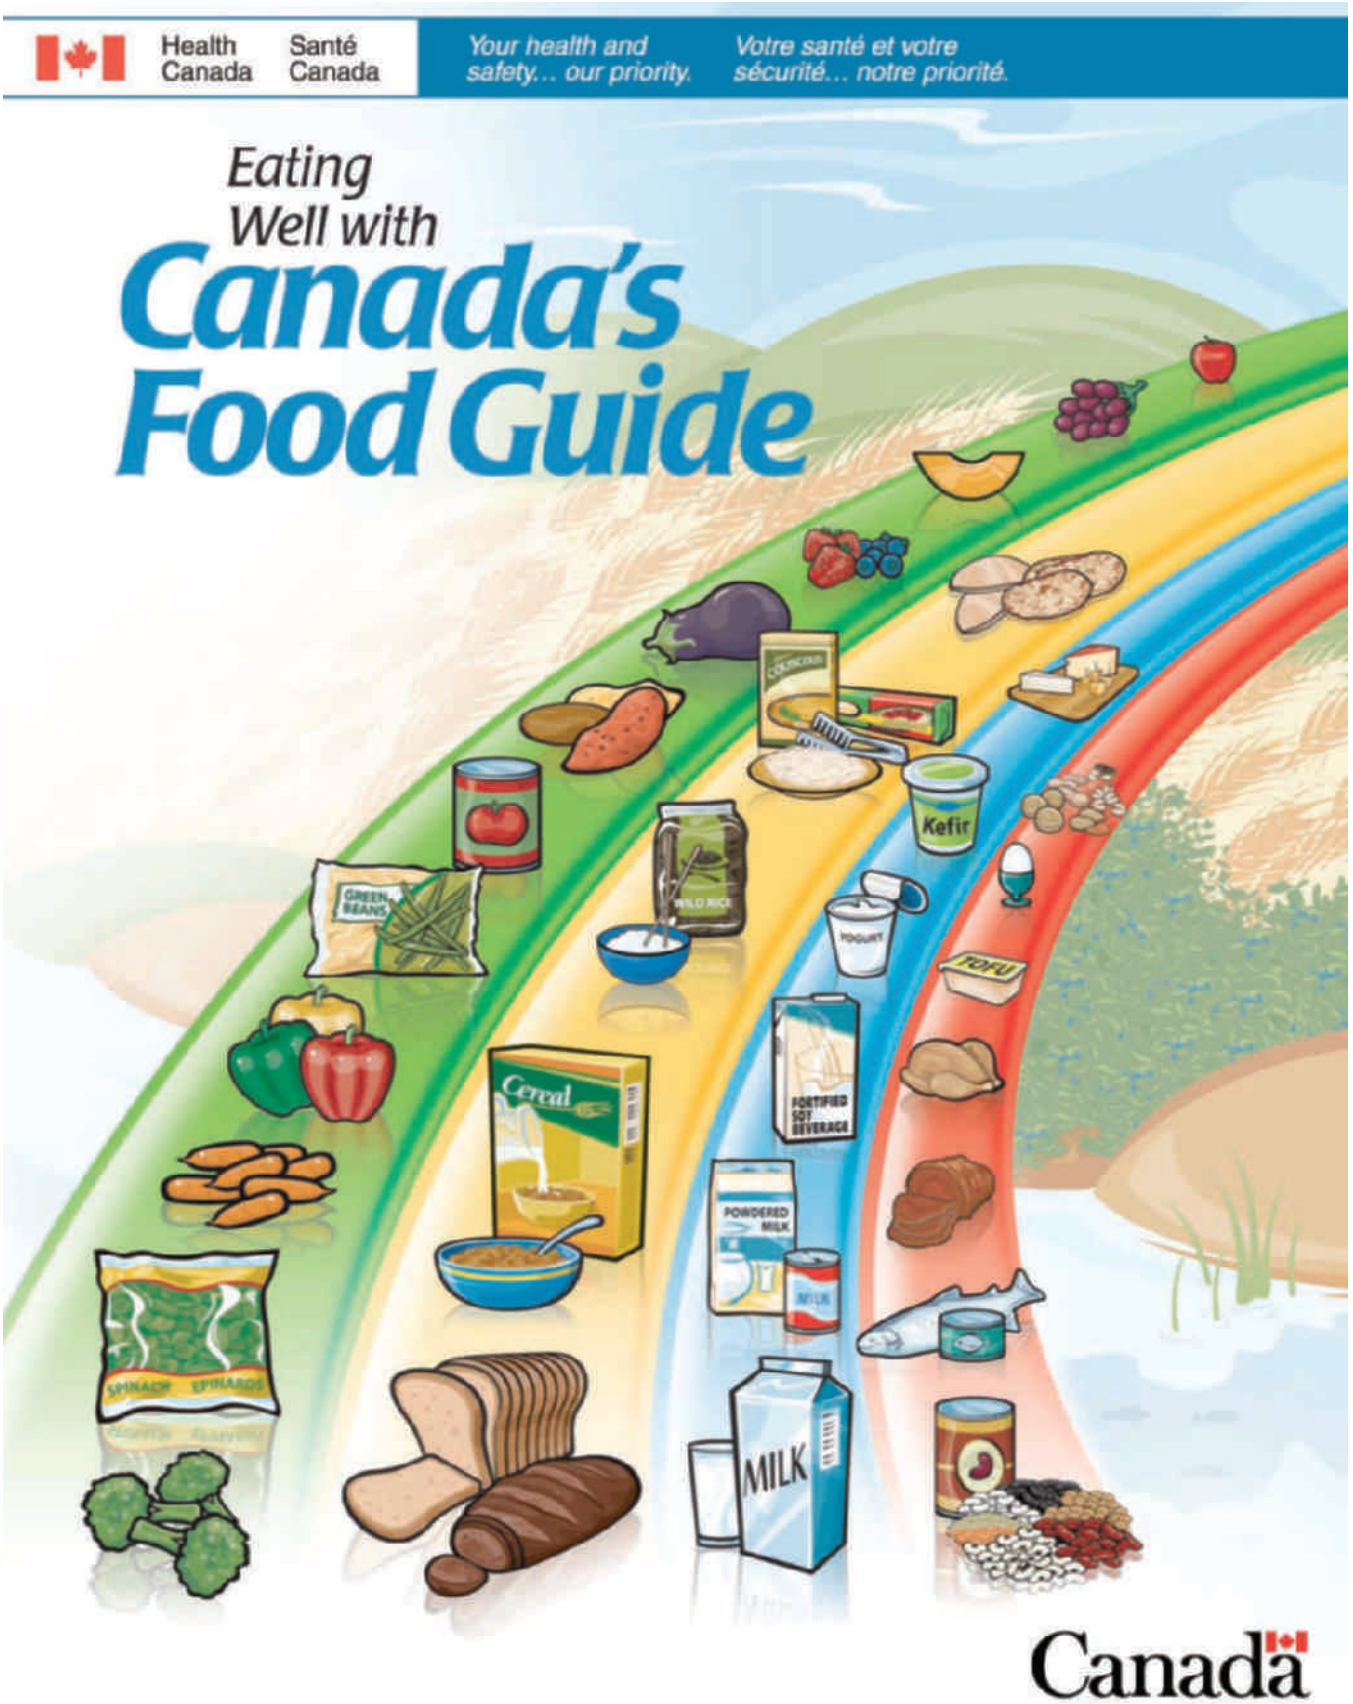

FIGURE I-1 *Eating Well with Canada's Food Guide*—continued

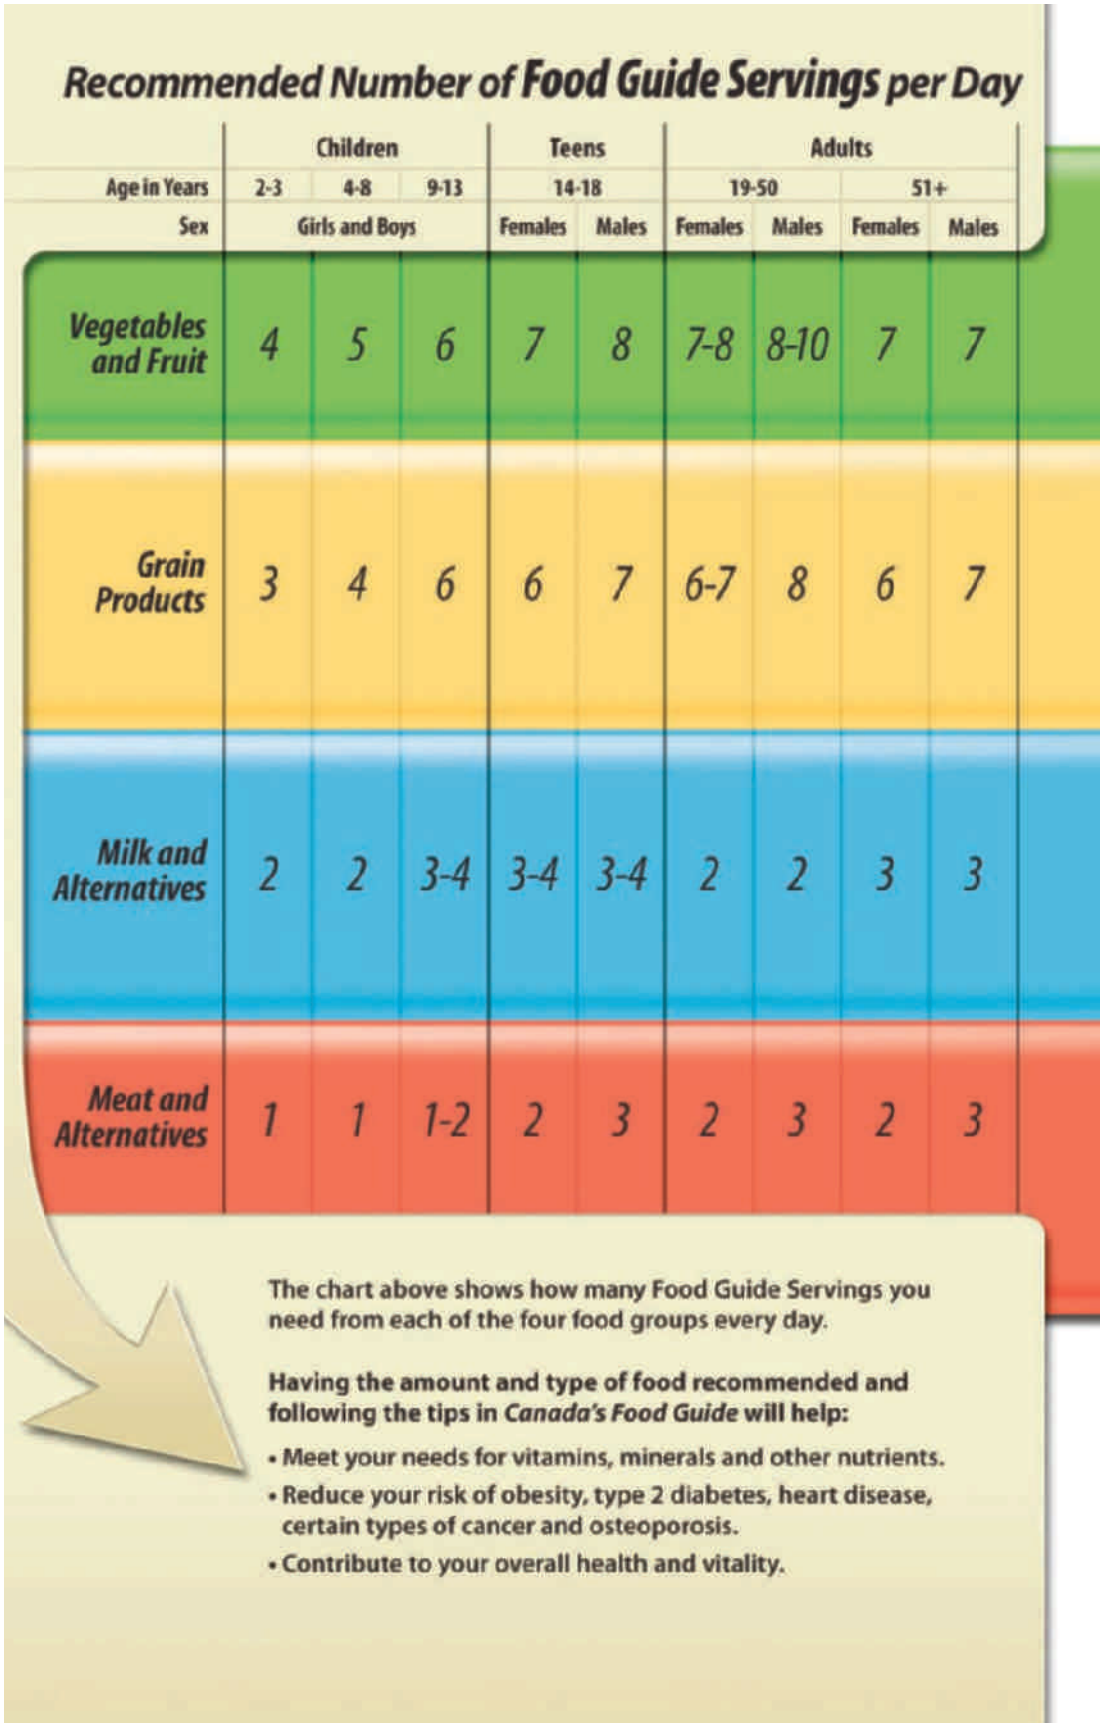

Recommended Number of Food Guide Servings per Day

	Children			Teens		Adults			
Age in Years	2-3	4-8	9-13	14-18		19-50		51+	
Sex	Girls and Boys			Females	Males	Females	Males	Females	Males
Vegetables and Fruit	4	5	6	7	8	7-8	8-10	7	7
Grain Products	3	4	6	6	7	6-7	8	6	7
Milk and Alternatives	2	2	3-4	3-4	3-4	2	2	3	3
Meat and Alternatives	1	1	1-2	2	3	2	3	2	3

The chart above shows how many Food Guide Servings you need from each of the four food groups every day.

Having the amount and type of food recommended and following the tips in *Canada's Food Guide* will help:

- Meet your needs for vitamins, minerals and other nutrients.
- Reduce your risk of obesity, type 2 diabetes, heart disease, certain types of cancer and osteoporosis.
- Contribute to your overall health and vitality.

FIGURE I-1 *Eating Well with Canada's Food Guide*—continued

FIGURE I-1 *Eating Well with Canada's Food Guide*—continued

Make each Food Guide Serving count...
wherever you are – at home, at school, at work or when eating out!

- **Eat at least one dark green and one orange vegetable each day.**
  - Go for dark green vegetables such as broccoli, romaine lettuce and spinach.
  - Go for orange vegetables such as carrots, sweet potatoes and winter squash.
- **Choose vegetables and fruit prepared with little or no added fat, sugar or salt.**
  - Enjoy vegetables steamed, baked or stir-fried instead of deep-fried.
- **Have vegetables and fruit more often than juice.**

- **Make at least half of your grain products whole grain each day.**
  - Eat a variety of whole grains such as barley, brown rice, oats, quinoa and wild rice.
  - Enjoy whole grain breads, oatmeal or whole wheat pasta.
- **Choose grain products that are lower in fat, sugar or salt.**
  - Compare the Nutrition Facts table on labels to make wise choices.
  - Enjoy the true taste of grain products. When adding sauces or spreads, use small amounts.

- **Drink skim, 1%, or 2% milk each day.**
  - Have 500 mL (2 cups) of milk every day for adequate vitamin D.
  - Drink fortified soy beverages if you do not drink milk.
- **Select lower fat milk alternatives.**
  - Compare the Nutrition Facts table on yogurts or cheeses to make wise choices.

- **Have meat alternatives such as beans, lentils and tofu often.**
- **Eat at least two Food Guide Servings of fish each week.***
  - Choose fish such as char, herring, mackerel, salmon, sardines and trout.
- **Select lean meat and alternatives prepared with little or no added fat or salt.**
  - Trim the visible fat from meats. Remove the skin on poultry.
  - Use cooking methods such as roasting, baking or poaching that require little or no added fat.
  - If you eat luncheon meats, sausages or prepackaged meats, choose those lower in salt (sodium) and fat.

Enjoy a variety of foods from the four food groups.

Satisfy your thirst with water!

Drink water regularly. It's a calorie-free way to quench your thirst. Drink more water in hot weather or when you are very active.

* Health Canada provides advice for limiting exposure to mercury from certain types of fish. Refer to www.healthcanada.gc.ca for the latest information.

FIGURE I-1 *Eating Well with Canada's Food Guide*—continued

Advice for different ages and stages...

Children

Following *Canada's Food Guide* helps children grow and thrive.

Young children have small appetites and need calories for growth and development.

- Serve small nutritious meals and snacks each day.
- Do not restrict nutritious foods because of their fat content. Offer a variety of foods from the four food groups.
- Most of all... be a good role model.

Women of childbearing age

All women who could become pregnant and those who are pregnant or breastfeeding need a multivitamin containing **folic acid** every day. Pregnant women need to ensure that their multivitamin also contains **iron**. A health care professional can help you find the multivitamin that's right for you.

Pregnant and breastfeeding women need more calories. Include an extra 2 to 3 Food Guide Servings each day.

Here are two examples:

- Have fruit and yogurt for a snack, or
- Have an extra slice of toast at breakfast and an extra glass of milk at supper.

Men and women over 50

The need for **vitamin D** increases after the age of 50.

In addition to following *Canada's Food Guide*, everyone over the age of 50 should take a daily vitamin D supplement of 10 µg (400 IU).

How do I count Food Guide Servings in a meal?

Here is an example:

Vegetable and beef stir-fry with rice, a glass of milk and an apple for dessert		
250 mL (1 cup) mixed broccoli, carrot and sweet red pepper	=	2 **Vegetables and Fruit** Food Guide Servings
75 g (2 ½ oz.) lean beef	=	1 **Meat and Alternatives** Food Guide Serving
250 mL (1 cup) brown rice	=	2 **Grain Products** Food Guide Servings
5 mL (1 tsp) canola oil	=	part of your **Oils and Fats** intake for the day
250 mL (1 cup) 1% milk	=	1 **Milk and Alternatives** Food Guide Serving
1 apple	=	1 **Vegetables and Fruit** Food Guide Serving

FIGURE I-1 *Eating Well with Canada's Food Guide*—continued

Eat well and be active today and every day!

The benefits of eating well and being active include:

- Better overall health.
- Lower risk of disease.
- A healthy body weight.
- Feeling and looking better.
- More energy.
- Stronger muscles and bones.

Be active

To be active every day is a step towards better health and a healthy body weight.

Canada's Physical Activity Guide recommends building 30 to 60 minutes of moderate physical activity into daily life for adults and at least 90 minutes a day for children and youth. You don't have to do it all at once. Add it up in periods of at least 10 minutes at a time for adults and five minutes at a time for children and youth.

Start slowly and build up.

Eat well

Another important step towards better health and a healthy body weight is to follow *Canada's Food Guide* by:

- Eating the recommended amount and type of food each day.
- Limiting foods and beverages high in calories, fat, sugar or salt (sodium) such as cakes and pastries, chocolate and candies, cookies and granola bars, doughnuts and muffins, ice cream and frozen desserts, french fries, potato chips, nachos and other salty snacks, alcohol, fruit flavoured drinks, soft drinks, sports and energy drinks, and sweetened hot or cold drinks.

Read the label

- Compare the Nutrition Facts table on food labels to choose products that contain less fat, saturated fat, trans fat, sugar and sodium.
- Keep in mind that the calories and nutrients listed are for the amount of food found at the top of the Nutrition Facts table.

Nutrition Facts

Per 0 mL (0 g)

Amount	% Daily Value
Calories 0	
Fat 0 g	**0 %**
Saturates 0 g	**0 %**
+ Trans 0 g	
Cholesterol 0 mg	
Sodium 0 mg	**0 %**
Carbohydrate 0 g	**0 %**
Fibre 0 g	**0 %**
Sugars 0 g	
Protein 0 g	

Vitamin A	0 %	Vitamin C	0 %
Calcium	0 %	Iron	0 %

Limit trans fat

When a Nutrition Facts table is not available, ask for nutrition information to choose foods lower in trans and saturated fats.

Take a step today…

- ✓ Have breakfast every day. It may help control your hunger later in the day.
- ✓ Walk wherever you can – get off the bus early, use the stairs.
- ✓ Benefit from eating vegetables and fruit at all meals and as snacks.
- ✓ Spend less time being inactive such as watching TV or playing computer games.
- ✓ Request nutrition information about menu items when eating out to help you make healthier choices.
- ✓ Enjoy eating with family and friends!
- ✓ Take time to eat and savour every bite!

Canada's *Meal Planning for Healthy Eating*

Beyond the Basics: Meal Planning for Healthy Eating, Diabetes Prevention and Management is Canada's system of meal planning.[1] Similar to the U.S. exchange system, *Beyond the Basics* sorts foods into groups and defines portion sizes to help people manage their blood glucose and maintain a healthy weight. Because foods that contain carbohydrate raise blood glucose, the food groups are organized into two sections—those that contain carbohydrate (presented in Table I-1) and those that contain little or no carbohydrate (shown in Table I-2). One portion from any of the food groups listed in Table I-1 provides about 15 grams of available carbohydrate (total carbohydrate minus fiber) and counts as one carbohydrate choice. Within each group, foods are identified as those to "choose more often" (generally higher in vitamins, minerals, and fiber) and those to "choose less often" (generally higher in sugar, saturated fat, or *trans* fat).

[1]The tables for the Canadian meal planning system are adapted from *Beyond the Basics: Meal Planning for Healthy Eating, Diabetes Prevention and Management,* copyright 2005, with permission of the Canadian Diabetes Association. Additional information is available from **www.diabetes.ca**.

Key:
● Choose more often
▲ Choose less often

TABLE I-1 Food Groups That Contain Carbohydrate

1 serving = 15 g carbohydrate or 1 carbohydrate choice

Food	Measure
Grains and starches: 15 g carbohydrate, 2 g protein, 0 g fat, 286 kJ (68 kcal)	
▲ Bagel, large	¼
▲ Bagel, small	½
▲ Bannock, fried	1.5″ × 2.5″
● Bannock, whole grain baked	1.5″ × 2.5″
● Barley, cooked	125 mL (½ c)
▲ Bread, white	30 g (1 oz)
● Bread, whole grain	30 g (1 oz)
● Bulgur, cooked	125 mL (½ c)
▲ Bun, hamburger or hotdog	½
▲ Cereal, flaked unsweetened	125 mL (½ c)
● Cereal, hot	¾ c
● Chapati, whole wheat (6″)	1
● Corn	125 mL (½ c)
● Couscous, cooked	125 mL (½ c)
▲ Crackers, soda type	7
▲ Croutons	⅔ c
● English muffin, whole grain	½
▲ French fries	10
● Millet, cooked	⅓ c
▲ Naan bread (6″)	¼
▲ Pancake (4″)	1
● Pasta, cooked	125 mL (½ c)
▲ Pita bread, white (6″)	1
● Pita bread, whole wheat (6″)	1
▲ Pizza crust (12″)	½
● Plantain, mashed	⅓ c
● Potatoes, boiled or baked	½ medium

(continued)

TABLE I-1 Food Groups That Contain Carbohydrate—continued

1 serving = 15 g carbohydrate or 1 carbohydrate choice

Food	Measure
Grains and starches: 15 g carbohydrate, 2 g protein, 0 g fat, 286 kJ (68 kcal)	
● Rice, cooked	⅓ c
● Roti, whole wheat (6″)	1
● Soup, thick type	250 mL (1 c)
● Sweet potato, mashed	⅓ c
▲ Taco shells (5″)	2
● Tortilla, whole wheat (6″)	1
▲ Waffle (4″)	1
Fruits:15 g carbohydrate, 1 g protein, 0 g fat, 269 kJ (64 kcal)	
● Apple	1 medium
● Apple sauce, unsweetened	125 mL (½ c)
● Banana	1 small
● Blackberries	500 mL (2 c)
● Cherries	15
● Fruit, canned in juice	125 mL (½ c)
▲ Fruit, dried	50 mL (¼ c)
● Grapefruit	1 small
● Grapes	15
● Kiwi	2 medium
▲ Juice	125 mL (½ c)
● Mango	½ medium
● Melon	250 mL (1 c)
● Orange	1 medium
● Other berries	250 mL (1 c)
● Pear	1 medium
● Pineapple	¾ c
● Plum	2 medium
● Raspberries	500 mL (2 c)
● Strawberries	500 mL (2 c)
Milk and alternatives: 15 g carbohydrate, 8 g protein, variable fat, 386–651 kJ (92–155 kcal)	
● Chocolate milk, 1%	125 mL (½ c)
● Evaporated milk, canned	125 mL (½ c)
● Milk, fluid	250 mL (1 c)
● Milk powder, skim	30 mL (2 tbs)
● Soy beverage, flavored	125 mL (½ c)
● Soy beverage, plain	250 mL (1 c)
● Soy yogurt, flavored	⅓ c
● Yogurt, nonfat, plain	¾ c
● Yogurt, skim, artificially sweetened	250 mL (1 c)
Other choices (sweet foods and snacks): 15 g carbohydrate, variable protein and fat	
▲ Brownies, unfrosted	2″ × 2″
▲ Cake, unfrosted	2″ × 2″
▲ Cookies, arrowroot or gingersnap	3–4
▲ Jam, jelly, marmalade	15 mL (1 tbs)
● Milk pudding, skim, no sugar added	125 mL (½ c)
▲ Muffin	1 small (2″)
▲ Oatmeal granola bar	1 (28 g)
● Popcorn, low fat	750 mL (3 c)
▲ Pretzels, low fat, large	7
▲ Pretzels, low fat, sticks	30
▲ Sugar, white	15 mL (3 tsp or packets)

TABLE I-2 Food Groups That Contain Little or No Carbohydrate

Food	Measure
Vegetables: To encourage consumption, most vegetables are considered "free"	
● Asparagus	
● Beans, yellow or green	
● Bean sprouts	
● Beets	
● Broccoli	
● Cabbage	
● Carrots	
● Cauliflower	
● Celery	
● Cucumber	
● Eggplant	
● Greens	
● Leeks	
● Mushrooms	
● Okra	
▲ Parsnips[a]	
▲ Peas[a]	
● Peppers	
▲ Rutabagas (turnips)[a]	
● Salad vegetables	
● Snow peas	
▲ Squash, winter[a]	
● Tomatoes	
Meat and alternatives: 0 g carbohydrate, 7 g protein, 3–5 g fat, 307 kJ (73 kcal)	
● Cheese, skim (<7% milk fat)	30 g (1 oz)
● Cheese, light (<17% milk fat)	30 g (1 oz)
▲ Cheese, regular (17–33% milk fat)	30 g (1 oz)
● Cottage cheese (1–2% milk fat)	50 mL (¼ c)
● Egg	1 large
▲ Fish, canned in oil	50 mL (¼ c)
● Fish, canned in water	50 mL (¼ c)
● Fish, fresh, cooked	30 g (1 oz)
● Hummus[b]	⅓ c
● Legumes, cooked[b]	125 mL (½ c)
● Meat, game, cooked	30 g (1 oz)

[a]These vegetables provide significant carbohydrate when more than 125 mL (½ c) is eaten.
[b]Legumes contain 15 g carbohydrate in a 125 mL (½ c) serving.

(continued)

TABLE I-2 Food Groups That Contain Little or No Carbohydrate—continued

Food	Measure
Meat and alternatives: 0 g carbohydrate, 7 g protein, 3–5 g fat, 307 kJ (73 kcal)	
● Meat, ground, lean, cooked	30 g (1 oz)
▲ Meat, ground, medium-regular, cooked	30 g (1 oz)
● Meat, lean, cooked	30 g (1 oz)
● Meat, organ or tripe, cooked	30 g (1 oz)
● Meat, prepared, low fat	30 g (1 oz)
▲ Meat, prepared, regular fat	30 g (1 oz)
▲ Meat, regular, cooked	30 g (1 oz)
● Peameal/back bacon, cooked	30 g (1 oz)
● Poultry, ground, lean, cooked	30 g (1 oz)
● Poultry, skinless, cooked	30 g (1 oz)
▲ Poultry/wings, skin on, cooked	30 g (1 oz)
● Shellfish, cooked	30 g (1 oz)
● Tofu (soybean)	½ block (100 g)
● Vegetarian meat alternatives	30 g (1 oz)
Fats: 0 g carbohydrate, 0 g protein, 5 g fat, 189 kJ (45 kcal)	
● Avocado	⅛
▲ Bacon	30 g (1 oz)
● Butter	5 mL (1 tsp)
▲ Cheese, spreadable	15 mL (1 tbs)
● Margarine, non-hydrogenated	5 mL (1 tsp)
▲ Mayonnaise, light	30 mL (2 tbs)
● Nuts	15 mL (1 tbs)
● Oil, canola or olive	5 mL (1 tsp)
● Salad dressing, regular	15 mL (1 tbs)
● Seeds	15 mL (1 tbs)
● Tahini	7.5 mL (½ tbs)
Extras: <5 g carbohydrate, 84 kJ (20 kcal)	
Broth	
Coffee	
Herbs and spices	
Ketchup	
Mustard	
Sugar-free soft drinks	
Sugar-free gelatin	
Tea

Healthy People 2010

Table 1-4 (p. 23) lists the objectives from the Nutrition and Overweight focus area of the Healthy People 2010 initiative. This table presents additional nutrition-related objectives from other focus areas.

TABLE J-1 Nutrition-Related Objectives from Other Focus Areas

Access to Quality Health Services

- Increase the proportion of persons appropriately counseled about health behaviors.

Arthritis, Osteoporosis, and Chronic Back Conditions

- Reduce the proportion of adults with osteoporosis.

Cancer

- Reduce the overall cancer death rate.
- Reduce the breast cancer death rate.
- Reduce the colorectal cancer death rate.
- Increase the proportion of physicians and dentists who counsel their at-risk patients about tobacco-use cessation, physical activity, and cancer screening.

Chronic Kidney Disease

- Increase the proportion of treated chronic kidney failure patients who have received counseling on nutrition, treatment choices, and cardiovascular care 12 months before the start of renal replacement therapy.

Diabetes

- Increase the proportion of persons with diabetes who receive formal diabetes education.
- Prevent diabetes.
- Reduce diabetes-related deaths among persons with diabetes.

Educational and Community-Based Programs

- Increase the proportion of middle, junior high, and senior high schools that provide school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol and other drug use; unintended pregnancy, HIV/AIDS, and STD infection; unhealthy dietary patterns; inadequate physical activity; and environmental health.
- Increase the proportion of worksites that offer a comprehensive employee health promotion program to their employees.
- Increase the proportion of employees who participate in employer-sponsored health promotion activities.
- Increase the proportion of community health promotion programs that address multiple Healthy People 2010 focus areas.
- Increase the proportion of local health departments that have established culturally appropriate and linguistically competent community health promotion and disease prevention programs.

Health Communication

- Increase the proportion of health-related World Wide Web sites that disclose information that can be used to assess the quality of the site.

Heart Disease and Stroke

- Reduce coronary heart disease deaths.
- Reduce stroke deaths.
- Reduce the proportion of adults with high blood pressure.

(continued)

TABLE J-1 Nutrition-Related Objectives from Other Focus Areas—continued

Heart Disease and Stroke, *continued*

- Increase the proportion of adults with high blood pressure who are taking action (for example, losing weight, increasing physical activity, or reducing sodium intake) to help control their blood pressure.
- Reduce the mean total blood cholesterol levels among adults.
- Reduce the proportion of adults with high total blood cholesterol levels.

Maternal, Infant, and Child Health

- Reduce low birthweight (LBW) and very low birthweight (VLBW).
- Increase the proportion of mothers who achieve a recommended weight gain during pregnancy.
- Reduce the occurrence of spina bifida and other neural tube defects.
- Increase the proportion of pregnancies begun with an optimum folate level.
- Increase abstinence from alcohol, cigarettes, and illicit drugs among pregnant women.
- Reduce the occurrence of fetal alcohol syndrome (FAS).
- Increase the proportion of mothers who breastfeed their babies.

Mental Health and Mental Disorders

- Reduce the relapse rates for persons with eating disorders, including anorexia nervosa and bulimia nervosa.

Physical Activity and Fitness

- Reduce the proportion of adults who engage in no leisure-time physical activity.
- Increase the proportion of adults who engage regularly, preferably daily, in moderate physical activity for at least 30 minutes per day.
- Increase the proportion of adults who engage in vigorous physical activity that promotes the development and maintenance of cardiorespiratory fitness 3 or more days per week for 20 or more minutes per occasion.
- Increase the proportion of adolescents who engage in moderate physical activity for at least 30 minutes on 5 or more of the previous 7 days.
- Increase the proportion of adolescents who engage in vigorous physical activity that promotes cardiorespiratory fitness 3 or more days per week for 20 or more minutes per occasion.
- Increase the proportion of adolescents who participate in daily school physical education.
- Increase the proportion of worksites offering employer-sponsored physical activity and fitness programs.

Substance Abuse

- Reduce average annual alcohol consumption.

Enteral Formulas

The large number of enteral formulas available allows patients to meet a wide variety of medical needs. The first step in narrowing the choice of formulas is to determine the patient's ability to digest and absorb nutrients. Table K–1 on pp. K-2 through K-3 lists examples of standard formulas for patients who can adequately digest and absorb nutrients, and Table K–2 on p. K-4 provides examples of elemental formulas for patients with a limited ability to digest or absorb nutrients. Each formula is listed only once, although a formula may have more than one use. A high-protein formula, for example, may also be a fiber-containing formula. Tables K–3 through K–5 on p. K-5 list modules that can be used to prepare modular formulas or enhance enteral formulas.

The information shown in this appendix reflects the literature provided by manufacturers and does not suggest endorsement by the authors. Manufacturers frequently add new formulas, discontinue old ones, and change formula composition. Consult the manufacturers' literature and websites for updates and additional examples of enteral formulas.* The following products are listed in this appendix:

- *Abbott Nutrition:* Glucerna, Jevity 1 Cal, Jevity 1.5 Cal, Nepro with Carb Steady, Optimental, Osmolite, Perative, Polycose Liquid, Polycose Powder, Promote, Promote with Fiber, Pulmocare
- *Mead Johnson Nutritionals:* Kindercal TF
- *Nestlé Nutrition:* Crucial, Nutren 1.0, Nutren 1.0 Fiber, Nutren 1.5, Nutren 2.0, Nutren Glytrol, Nutren Junior, Nutren ProBalance, Nutren Pulmonary, Nutren Renal, Nutren Replete, NutriHep, Peptamen, Peptamen Junior
- *Novartis Medical Nutrition:* Compleat Pediatric, Impact, Impact 1.5, Impact Glutamine, Isosource, Isosource HN, Isosource VHN, MCT Oil, Microlipid, Novasource Pulmonary, Novasource Renal, Resource Beneprotein Instant Protein Powder, Resource Diabetic TF, Vivonex Pediatric, Vivonex Plus, Vivonex T.E.N.

*Sources for the information in this appendix: Abbott Nutrition, www.abbottnutrition.com, Mead Johnson Nutritionals, www.meadjohnson.com, Nestlé Nutrition, www.nestle-nutrition.com, Novartis Medical Nutrition, www.novartisnutrition.com.

TABLE K-1 Standard Formulas

Product	Volume to Meet 100% RDI[a] (mL)	Energy (kcal/mL)	Protein or Amino Acids (g/L)	Carbohydrate (g/L)	Fat (g/L)	Notes
Lactose-Free, Standard Formulas						
Isosource	1165	1.20	43	170	39	20% fat from MCT
Nutren 1.0	1500	1.00	40	127	38	25% fat from MCT
Osmolite 1 Cal	1321	1.06	44	144	35	20% fat from MCT
Lactose-Free, Fiber-Containing Formulas						
Jevity 1 Cal	1321	1.06	44	155	35	14 g fiber/L
Nutren 1.0 Fiber	1500	1.00	40	127	38	14 g fiber/L
Nutren ProBalance	1000	1.20	54	156	41	10 g fiber/L
Promote with Fiber	1000	1.00	63	138	28	14 g fiber/L
Lactose-Free, High-kCalorie Formulas						
Jevity 1.5 Cal	1500	1.50	64	216	50	22 g fiber/L
Nutren 1.5	1000	1.50	60	169	68	50% fat from MCT
Nutren 2.0	750	2.00	80	196	104	75% fat from MCT
Lactose-Free, High-Protein Formulas						
Isosource HN	1165	1.20	53	160	39	20% fat from MCT, low residue
Isosource VHN	1250	1.00	62	130	29	50% fat from MCT, low residue
Promote	1000	1.00	63	130	26	20% fat from MCT, low residue
Special-Use Formulas: Pediatric (1 to 10 years)						
Compleat Pediatric	Varies[b]	1.00	38	130	39	Blenderized formula, 6.8 g fiber/L
Kindercal TF	Varies[b]	1.06	30	135	44	20% fat from MCT
Nutren Junior	Varies[b]	1.00	30	110	50	21% fat from MCT
Special-Use Formulas: Glucose Intolerance						
Glucerna	1420	1.00	42	96	54	14 g fiber/L
Nutren Glytrol	1400	1.00	45	100	48	15 g fiber/L, 20% fat from MCT
Resource Diabetic TF	1250	1.00	50	82	49	15 g fiber/L
Special-Use Formulas: Immune System Support						
Impact	1500	1.00	56	130	28	Enriched with arginine, nucleic acids, and omega-3 fatty acids
Impact 1.5	1250	1.50	84	140	69	Same as above
Impact Glutamine	1000	1.30	78	150	43	Same as above, and enriched with glutamine
Special-Use Formulas: Renal Failure						
Nepro with Carb Steady	948	1.80	81	167	96	Low potassium, low phosphorus; to be used after dialysis has been instituted
Novasource Renal	1000	2.00	74	200	100	Low in electrolytes; to be used after dialysis has been instituted
Nutren Renal	1000	2.00	70	205	104	50% fat from MCT; enriched with vitamins C and B_6, folate, zinc, and selenium; to be used after dialysis has been instituted

(continued)

TABLE K-1 Standard Formulas—*continued*

Product	Volume to Meet 100% RDI[a] (mL)	Energy (kcal/mL)	Protein or Amino Acids (g/L)	Carbohydrate (g/L)	Fat (g/L)	Notes
Special-Use Formulas: Respiratory Insufficiency						
Novasource Pulmonary	933	1.50	75	150	68	8 g fiber/L
Nutren Pulmonary	1000	1.50	68	100	95	55% kcal from fat, 40% fat from MCT
Pulmocare	947	1.50	63	106	93	55% kcal from fat, 20% fat from MCT, enriched with antioxidant nutrients
Special-Use Formulas: Wound Healing						
Isosource VHN	1250	1.00	62	130	29	10 g fiber/L, enriched with vitamins A and C and zinc
Nutren Replete	1000	1.00	62	113	34	Enriched with vitamins A and C and zinc; 25% fat from MCT
TwoCal HN	948	2.00	84	219	91	Enriched with prebiotic fibers

NOTE: MCT = Medium-chain triglycerides
[a]RDI = Reference Daily Intakes, which are labeling standards for vitamins, minerals, and protein. Consuming 100 percent of the RDI will meet the nutrient needs of most people using the product.
[b]Depends on age of child

TABLE K-2 Elemental Formulas

Product	Volume to Meet 100% RDI[a] (mL)	Energy (kcal/mL)	Protein or Amino Acids (g/L)	Carbohydrate (g/L)	Fat (g/L)	Notes
Special-Use Elemental Formula: Hepatic Insufficiency						
NutriHep	1000	1.50	40	290	21	Free amino acids, high in branched-chain amino acids and low in aromatic amino acids
Special-Use Elemental Formulas: Immune System Support						
Crucial	1000	1.50	94	134	68	Enriched with arginine, antioxidant nutrients, and zinc
Perative	1155	1.30	67	180	37	Enriched with arginine and prebiotic fibers
Vivonex Plus	1800	1.00	45	190	7	Powder form; 100% free amino acids, enriched with glutamine, arginine, and branched-chain amino acids

NOTE: MCT = Medium-chain triglycerides
[a]RDI = Reference Daily Intakes, which are labeling standards for vitamins, minerals, and protein. Consuming 100 percent of the RDI will meet the nutrient needs of most people using the product.
[b]Depends on age of child

(continued)

TABLE K-2 Elemental Formulas—*continued*

Product	Volume to Meet 100% RDI[a] (mL)	Energy (kcal/mL)	Protein or Amino Acids (g/L)	Carbohydrate (g/L)	Fat (g/L)	Notes
Special-Use Elemental Formulas: Malabsorption						
Optimental	1422	1.00	51	139	28	Contains MCT and arginine, enriched with antioxidants and omega-3 fatty acids
Peptamen	1500	1.00	40	127	39	70% fat from MCT
Vivonex T.E.N.	2000	1.00	38	210	3	Powder form, 100% free amino acids, enriched with glutamine
Special-Use Elemental Formulas: Pediatric (1 to 10 years)						
Peptamen Junior	Varies[b]	1.00	30	138	38	60% fat from MCT
Vivonex Pediatric	Varies[b]	0.80	24	130	24	Powder form, 100% free amino acids

NOTE: MCT = Medium-chain triglycerides
[a]RDI = Reference Daily Intakes, which are labeling standards for vitamins, minerals, and protein. Consuming 100 percent of the RDI will meet the nutrient needs of most people using the product.
[b]Depends on age of child

TABLE K-3 Protein Modules

Product	Form	Major Protein Source	Energy (kcal/g)	Protein (g/100 g)
Resource Beneprotein Instant Protein Powder	Powder	Whey protein	3.6	86

TABLE K-4 Carbohydrate Modules

Product	Form	Major Carbohydrate Source	Energy
Polycose Liquid	Liquid	Hydrolyzed cornstarch	2.0 kcal/mL
Polycose Powder	Powder	Hydrolyzed cornstarch	3.8 kcal/g

TABLE K-5 Fat Modules

Product	Form	Major Fat Source	Energy (kcal/mL)	Fat (g/100 mL)
MCT Oil	Liquid	Coconut oil	7.7	93
Microlipid	Liquid	Safflower oil	4.5	50

Glossary

Many medical terms have their origins in Latin or Greek. By learning a few common derivations, you can glean the meaning of words you have never heard of before. For example, once you know that "hyper" means above normal, "glyc" means glucose, and "emia" means blood, you can easily determine that "hyperglycemia" means high blood glucose. The derivations at left will help you to learn many terms presented in this glossary.

GENERAL

a- or *an-* = not or without
ana- = up
ant- or *anti-* = against
ante- or *pre-* or *pro-* = before
cata- = down
co- = with or together
bi- or *di-* = two, twice
dys- or *mal-* = bad, difficult, painful
endo- = inner or within
epi- = upon
exo- = outside of or without
extra- = outside of, beyond, or in addition
gen- or *-gen* = gives rise to, producing
homeo- = like, similar, constant unchanging state
hyper- = over, above, excessive
hypo- = below, under, beneath
in- = not
inter- = between, in the midst
intra- = within
-itis = infection or inflammation
-lysis = break
macro- = large or long
micro- = small
mono- = one, single
neo- = new, recent
oligo- = few or small
-osis or *-asis* = condition
para- = near
peri- = around, about
poly- = many or much
semi- = half
-stat or *-stasis-* = stationary
tri- = three

BODY

angi- or *vaso-* = vessel
arterio- = artery
cardiac or *cardio-* = heart
-cyte = cell
enteron = intestine
gastro- = stomach
hema- or *-emia* = blood
hepatic = liver
myo- or *sarco-* = muscle
nephr- or *renal* = kidney
neuro- = nerve
osteo- = bone
pulmo- = lung
ure- or *-uria* = urine
vena = vein

CHEMISTRY

-al = aldehyde
-ase = enzyme
-ate = salt
glyc- or *gluc-* = sweet (glucose)
hydro- or *hydrate* = water
lipo- = lipid
-ol = alcohol
-ose = carbohydrate
saccha- = sugar

2-in-1 solution: a parenteral solution that contains dextrose and amino acids, but excludes lipids.

24-hour recall: a record of foods consumed in the previous 24 hours; sometimes modified to include foods consumed in a typical day.

A

abscesses (AB-sess-es): accumulated pus that is surrounded by inflamed tissue.

absorption: the uptake of nutrients by the cells of the small intestine for transport into either the blood or the lymph.

Acceptable Daily Intake (ADI): the estimated amount of a sweetener that individuals can safely consume each day over the course of a lifetime without adverse effect.

Acceptable Macronutrient Distribution Ranges (AMDR): ranges of intakes for the energy nutrients that provide adequate energy and nutrients and reduce the risk of chronic diseases.

accredited: approved; in the case of medical centers or universities, certified by an agency recognized by the U.S. Department of Education.

acesulfame (AY-sul-fame) **potassium:** an artificial sweetener composed of an organic salt that has been approved for use in both the United States and Canada; also known as **acesulfame-K** because K is the chemical symbol for potassium.

acetaldehyde (ass-et-AL-duh-hide): an intermediate in alcohol metabolism.

acetone breath: a distinctive fruity odor on the breath of a person with ketosis.

acetyl CoA (ASS-eh-teel, or ah-SEET-il, coh-AY): a 2-carbon compound (acetate, or acetic acid, shown in Figure 5-1 on p. 140) to which a molecule of CoA is attached.

achalasia (ack-ah-LAY-zhah): an esophageal disorder characterized by weakened peristalsis and impaired relaxation of the lower esophageal sphincter.

achlorhydria (AY-clor-HIGH-dree-ah): absence of gastric acid secretion.

acid controllers: medications used to prevent or relieve indigestion by suppressing production of acid in the stomach; also called *H2 blockers*. Common brands include Pepcid AC, Tagamet HB, Zantac 75, and Axid AR.

acid-base balance: the equilibrium in the body between acid and base concentrations (see Chapter 12).

acidosis (assi-DOE-sis): above-normal acidity in the blood and body tissues; depresses the central nervous system and can lead to disorientation and, eventually, coma.

acids: compounds that release hydrogen ions in a solution.

acne: a chronic inflammation of the skin's follicles and oil-producing glands, which leads to an accumulation of oils inside the ducts that surround hairs; usually associated with the maturation of young adults.

acquired immune deficiency syndrome (AIDS): the late stage of illness caused by infection with the human immunodeficiency virus (HIV); characterized by severe damage to immune function.

acupuncture (AK-you-PUNK-chur): a therapy that involves inserting thin needles into the skin at specific anatomical points, allegedly to correct disruptions in the flow of energy within the body.

acute PEM: protein-energy malnutrition caused by recent severe food restriction; characterized in children by thinness for height (wasting).

acute renal failure: abrupt loss of kidney function over a period of hours or days; also known as *acute kidney injury*.

acute respiratory distress syndrome (ARDS): respiratory failure triggered by severe lung injury; a medical emergency that causes dyspnea and pulmonary edema and usually requires assisted (mechanical) ventilation.

acute-phase proteins: plasma proteins released from the liver at the onset of acute infection. An example is **C-reactive protein**, which is considered one of the main indicators of severe infection and has antimicrobial effects.

acute-phase response: changes in body chemistry resulting from infection, inflammation, or injury; characterized by alterations in plasma proteins.

adaptive immunity: immunity that is specific for particular antigens; it adapts to antigens in an individual's environment and is characterized by "memory" for particular antigens. Also called **acquired immunity**.

adaptive thermogenesis: adjustments in energy expenditure related to changes in environment such as extreme cold and to physiological events such as overfeeding, trauma, and changes in hormone status.

added sugars: sugars and syrups used as an ingredient in the processing and preparation of foods such as breads, cakes, beverages, jellies, and ice cream as well as sugars eaten separately or added to foods at the table.

adequacy (dietary): providing all the essential nutrients, fiber, and energy in amounts sufficient to maintain health.

Adequate Intake (AI): the average daily amount of a nutrient that appears sufficient to maintain a specified criterion; a value used as a guide for nutrient intake when an RDA cannot be determined.

adiponectin (AH-dih-poe-NECK-tin): a hormone produced by adipose cells that improves insulin sensitivity.

adipose (ADD-ih-poce) **tissue:** the body's fat tissue; consists of masses of triglyceride-storing cells.

adolescence: the period from the beginning of puberty until maturity.

adrenal glands: glands adjacent to, and just above, each kidney.

adrenocorticotropin (ad-REE-noh-KORE-tee-koh-TROP-in) or **ACTH:** a hormone, so named because it stimulates (trope) the adrenal cortex. The adrenal gland, like the pituitary, has two parts, in this case an outer portion (cortex) and an inner core (medulla).

advance directive: written or oral instruction regarding one's preferences for medical treatment to be used in the event of becoming incapacitated.

advanced glycation end products (AGEs): reactive compounds formed after glucose combines with protein; AGEs can damage tissues and lead to diabetic complications.

adverse reactions: unusual responses to food (including intolerances and allergies).

aerobic (air-ROE-bic): requiring oxygen.

AIDS-defining illnesses: diseases and complications associated with the later stages of an HIV infection, including wasting, recurrent bacterial pneumonia, opportunistic infections, and certain cancers.

alcohol: a class of organic compounds containing hydroxyl (OH) groups.

alcohol abuse: a pattern of drinking that includes failure to fulfill work, school, or home responsibilities; drinking in situations that are physically dangerous (as in driving while intoxicated); recurring alcohol-related legal problems (as in aggravated assault charges); or continued drinking despite ongoing social problems that are caused by or worsened by alcohol.

alcohol dehydrogenase (dee-high-DROJ-eh-nayz): an enzyme active in the stomach and the liver that converts ethanol to acetaldehyde.

alcoholism: a pattern of drinking that includes a strong craving for alcohol, a loss of control and an inability to stop drinking once begun, withdrawal symptoms (nausea, sweating, shakiness, and anxiety) after heavy drinking, and the need for increasing amounts of alcohol to feel "high."

alcohol-related birth defects (ARBD): malformations in the skeletal and organ systems (heart, kidneys, eyes, ears) associated with prenatal alcohol exposure.

alcohol-related neurodevelopmental disorder (ARND): abnormalities in the central nervous system and cognitive development associated with prenatal alcohol exposure.

aldosterone (al-DOS-ter-own): a hormone secreted by the adrenal glands that regulates blood pressure by increasing the reabsorption of sodium by the kidneys. Aldosterone also regulates chloride and potassium concentrations.

alitame (AL-ih-tame): an artificial sweetener composed of two amino acids (alanine and aspartic acid); FDA approval pending.

alkalosis (alka-LOE-sis): above-normal alkalinity (base) in the blood and body fluids.

allergen: any substance that triggers an inappropriate immune response.

allergy: an excessive and inappropriate immune reaction to a harmless substance.

alpha-lactalbumin (lact-AL-byoo-min): a major protein in human breast milk, as opposed to **casein** (CAY-seen), a major protein in cow's milk.

alpha-tocopherol: the active vitamin E compound.

alveoli (al-VEE-oh-lie): air sacs in the lungs. One sac is an *alveolus.*

Alzheimer's disease: a degenerative disease of the brain involving memory loss and major structural changes in neuron networks; also known as *senile dementia of the Alzheimer's type (SDAT), primary degenerative dementia of senile onset,* or *chronic brain syndrome.*

amenorrhea (ay-MEN-oh-REE-ah): the absence of or cessation of menstruation. **Primary amenorrhea** is menarche delayed beyond 16 years of age. **Secondary amenorrhea** is the absence of three to six consecutive menstrual cycles.

American Dietetic Association (ADA): the professional organization of dietitians in the United States. The Canadian equivalent is Dietitians of Canada, which operates similarly.

amino (a-MEEN-oh) **acids:** building blocks of proteins. Each contains an amino group, an acid group, a hydrogen atom, and a distinctive side group, all attached to a central carbon atom.

amino acid pool: the supply of amino acids derived from either food proteins or body proteins that collect in the cells and circulating blood and stand ready to be incorporated in proteins and other compounds or used for energy.

amino acid scoring: a measure of protein quality assessed by comparing a protein's amino acid pattern with that of a reference protein; sometimes called *chemical scoring.*

ammonia: a compound with the chemical formula NH_3; produced during the deamination of amino acids.

amniotic (am-nee-OTT-ic) **sac:** the "bag of waters" in the uterus, in which the fetus floats.

amylase (AM-ih-lace): an enzyme that hydrolyzes amylose (a form of starch). Amylase is a *carbohydrase*, an enzyme that breaks down carbohydrates.

anabolism (an-AB-o-lism): reactions in which small molecules are put together to build larger ones. Anabolic reactions require energy.

anaerobic (AN-air-ROE-bic): not requiring oxygen.

anaphylactic (ana-fill-LAC-tic) **shock:** a life-threatening, whole-body allergic reaction to an offending substance.

anaphylaxis: a severe allergic reaction that may include gastrointestinal upset, skin reactions, respiratory symptoms, and low blood pressure, potentially leading to shock.

anemia (ah-NEE-me-ah): literally, "too little blood." Anemia is any condition in which too few red blood cells are present, or the red blood cells are immature (and therefore large) or too small or contain too little hemoglobin to carry the normal amount of oxygen to the tissues. It is not a disease itself but can be a symptom of many different disease conditions, including many nutrient deficiencies, bleeding, excessive red blood cell destruction, and defective red blood cell formation.

anemia of chronic disease: anemia that develops in persons with chronic illness; may resemble iron-deficiency anemia even though iron stores are often adequate.

anencephaly (AN-en-SEF-a-lee): an uncommon and always fatal type of neural tube defect; characterized by the absence of a brain.

aneurysm (AN-you-rih-zum): an abnormal enlargement or bulging of a blood vessel (usually an artery) caused by damage to or weakness in the blood vessel wall.

angina (an-JYE-nah or AN-ji-nah) **pectoris:** a condition caused by ischemia in the heart muscle that results in discomfort or dull pain in the chest region. The pain often radiates to the left shoulder and arm or to the back, neck, and lower jaw.

angiotensin (AN-gee-oh-TEN-sin): a hormone involved in blood pressure regulation. Its precursor protein is called *angiotensinogen*; it is activated by *renin*, an enzyme from the kidneys.

anions (AN-eye-uns): negatively charged ions.

anorexia (an-oh-RECK-see-ah) **nervosa:** an eating disorder characterized by a refusal to maintain a minimally normal body weight and a distortion in perception of body shape and weight.

antacids: medications used to relieve indigestion by neutralizing acid in the stomach. Common brands include Alka-Seltzer, Maalox, Rolaids, and Tums.

antagonist: a competing factor that counteracts the action of another factor. When a drug displaces a vitamin from its site of action, the drug renders the vitamin ineffective and thus acts as a vitamin antagonist.

anthropometric (AN-throw-poe-MET-rick): relating to measurement of the physical characteristics of the body, such as height and weight.

antibodies: large proteins of the blood and body fluids, produced by the immune system in response to the invasion of the body by foreign molecules (usually proteins called *antigens*). Antibodies combine with and inactivate the foreign invaders, thus protecting the body.

antidiuretic hormone (ADH): a hormone produced by the pituitary gland in response to dehydration (or a high sodium concentration in the blood). It stimulates the kidneys to reabsorb more water and therefore prevents water loss in urine (also called *vasopressin*). (This ADH should not be confused with the enzyme alcohol dehydrogenase, which is also sometimes abbreviated ADH.)

antigens: substances that elicit the formation of antibodies or an inflammation reaction from the immune system. A bacterium, a virus, a toxin, and a protein in food that causes allergy are all examples of antigens.

antioxidant: in the body, a substance that significantly decreases the adverse effects of free radicals on normal physiological functions.

antioxidants: as a food additive, preservatives that delay or prevent rancidity of fats in foods and other damage to food caused by oxygen.

antiscorbutic (AN-tee-skor-BUE-tik) **factor:** the original name for vitamin C.

anus (AY-nus): the terminal outlet of the GI tract.

aorta (ay-OR-tuh): the large, primary artery that conducts blood from the heart to the body's smaller arteries.

aplastic anemia: anemia characterized by the inability of bone marrow to produce adequate numbers of blood cells. Causes include genetic defects, viruses, radiation treatment, and drug toxicity.

appendix: a narrow blind sac extending from the beginning of the colon that stores lymph cells.

appetite: the integrated response to the sight, smell, thought, or taste of food that initiates or delays eating.

arachidonic (a-RACK-ih-DON-ic) **acid:** an omega-6 polyunsaturated fatty acid with 20 carbons and four double bonds; present in small amounts in meat and other animal products and synthesized in the body from linoleic acid.

aromatherapy: inhalation of oil extracts from plants to cure illness or enhance health.

arteries: vessels that carry blood from the heart to the tissues.

artesian water: water drawn from a well that taps a confined aquifer in which the water is under pressure.

arthritis: inflammation of a joint, usually accompanied by pain, swelling, and structural changes.

artificial fats: zero-energy fat replacers that are chemically synthesized to mimic the sensory and cooking qualities of naturally occurring fats but are totally or partially resistant to digestion.

artificial sweeteners: sugar substitutes that provide negligible, if any, energy; sometimes called **nonnutritive sweeteners**.

ascites (ah-SIGH-teez): an abnormal accumulation of fluid in the abdominal cavity.

ascorbic acid: one of the two active forms of vitamin C (see Figure 10-15). Many people refer to vitamin C by this name.

-ase (ACE): a word ending denoting an enzyme. The word beginning often identifies the compounds the enzyme works on. Examples include:
- **carbohydrase** (KAR-boe-HIGH-drase), an enzyme that hydrolyzes carbohydrates.
- **lipase** (LYE-pase), an enzyme that hydrolyzes lipids (fats).
- **protease** (PRO-tee-ase), an enzyme that hydrolyzes proteins.

aspartame (ah-SPAR-tame or ASS-par-tame): an artificial sweetener composed of two amino acids (phenylalanine and aspartic acid); approved for use in both the United States and Canada.

aspiration: drawing in by suction or breathing; a common complication of enteral feedings in which foreign material enters the lungs, often from GI secretions or the reflux of stomach contents.

aspiration pneumonia: a lung disease resulting from the abnormal entry of foreign material; caused by either bacterial infection or irritation of the lower airways.

atherogenic: able to initiate or promote atherosclerosis.

atherosclerosis (ATH-er-oh-scler-OH-sis): a type of artery disease characterized by plaques (accumulations of lipid-containing material) on the inner walls of the arteries (see Chapter 27).

atoms: the smallest components of an element that have all of the properties of the element.

ATP or **adenosine** (ah-DEN-oh-seen) **triphosphate** (try-FOS-fate): a common high-energy compound composed of a purine (adenine), a sugar (ribose), and three phosphate groups.

atrophic (a-TRO-fik) **gastritis** (gas-TRY-tis): chronic inflammation of the stomach accompanied by a diminished size and functioning of the mucous membrane and glands.

autoimmune: an immune response directed against the body's own tissues.

autoimmune diseases: diseases characterized by an attack of immune defenses on the body's own cells.

autonomic nervous system: the division of the nervous system that controls the body's automatic responses. Its two branches are the **sympathetic** branch, which helps the body respond to stressors from the outside environment, and the **parasympathetic** branch, which regulates normal body activities between stressful times.

ayurveda: a traditional medical system from India that promotes the use of diet, herbs, meditation, massage, and yoga for preventing and treating illness.

B

B cell: a lymphocyte that produces antibodies.

bacterial cholangitis (KOH-lan-JYE-tis): bacterial infection involving the bile ducts.

bacterial overgrowth: excessive bacterial colonization of the stomach and small intestine; may be caused by low gastric acidity, altered gastrointestinal motility, mucosal damage, or contamination.

balance (dietary): providing foods in proportion to each other and in proportion to the body's needs.

bariatric (BAH-ree-AH-trik) **surgery:** surgery that treats severe obesity.

Barrett's esophagus: a condition in which esophageal cells damaged by chronic exposure to stomach acid are replaced by cells that resemble those in the stomach or small intestine, sometimes becoming cancerous.

basal metabolic rate (BMR): the rate of energy use for metabolism under specified conditions: after a 12-hour fast and restful sleep, without any physical activity or emotional excitement, and in a comfortable setting. It is usually expressed as kcalories per kilogram body weight per hour.

basal metabolism: the energy needed to maintain life when a body is at complete digestive, physical, and emotional rest.

bases: compounds that accept hydrogen ions in a solution.

beer: an alcoholic beverage brewed by fermenting malt and hops.

behavior modification: the changing of behavior by the manipulation of antecedents (cues or environmental factors that trigger behavior), the behavior itself, and consequences (the penalties or rewards attached to behavior).

belching: the expulsion of gas from the stomach through the mouth.

beneficence (be-NEF-eh-sense): the act of performing beneficial services rather than harmful ones.

beriberi: the thiamin-deficiency disease.

beta-carotene (BAY-tah KARE-oh-teen): one of the carotenoids; an orange pigment and vitamin A precursor found in plants.

bicarbonate: an alkaline compound with the formula HCO_3 that is secreted from the pancreas as part of the pancreatic juice. (Bicarbonate is also produced in all cell fluids from the dissociation of cabonic acid to help maintain the body's acid-base balance.)

bifidus (BIFF-id-us, or by-FEED-us) **factors:** factors in colostrum and breast milk that favor the growth of the "friendly" bacterium *Lactobacillus* (lack-toh-ba-SILL-us) *bifidus* in the infant's intestinal tract, so that other, less desirable intestinal inhabitants will not flourish.

bile: an emulsifier that prepares fats and oils for digestion; an exocrine secretion made by the liver, stored in the gallbladder, and released into the small intestine when needed.

biliary system: the gallbladder and ducts that deliver bile from the liver and gallbladder to the small intestine.

binders: chemical compounds in foods that combine with nutrients (especially minerals) to form complexes the body cannot absorb. Examples include **phytates** (FYE-tates) and **oxalates** (OCK-sa-lates).

binge-eating disorder: an eating disorder with criteria similar to those of bulimia nervosa, excluding purging or other compensatory behaviors.

bioavailability: the rate at and the extent to which a nutrient is absorbed and used.

bioelectrical or **bioelectromagnetic therapies:** therapies that involve the unconventional use of electric or magnetic fields to cure illness.

biofeedback: a technique in which individuals are trained to gain voluntary control of certain physiological processes, such as skin temperature or brain wave activity, to help reduce stress and anxiety.

biofield therapies: healing methods based on the belief that illnesses can be healed by manipulating energy fields that purportedly surround and penetrate the body. Examples include *acupuncture, qi gong*, and *therapeutic touch.*

biological value (BV): a measure of protein quality assessed by measuring the amount of protein nitrogen that is retained from a given amount of protein nitrogen absorbed.

biotin (BY-oh-tin): a B vitamin that functions as a coenzyme in metabolism.

blenderized formulas: enteral formulas that are prepared by using a food blender to mix and puree whole foods.

blind experiment: an experiment in which the subjects do not know whether they are members of the experimental group or the control group.

blood lipid profile: results of blood tests that reveal a person's total cholesterol, triglycerides, and various lipoproteins.

body composition: the proportions of muscle, bone, fat, and other tissue that make up a person's total body weight.

body mass index (BMI): an index of a person's weight in relation to height; determined by dividing the weight (in kilograms) by the square of the height (in meters).

bolus (BOH-lus): a portion; with respect to food, the amount swallowed at one time.

bolus (BOH-lus) **feeding:** delivery of about 250 to 500 milliliters of formula in less than 20 minutes.

bomb calorimeter (KAL-oh-RIM-eh-ter): an instrument that measures the heat energy released when foods are burned, thus providing an estimate of the potential energy of the foods.

bone density: a measure of bone strength. When minerals fill the bone matrix (making it dense), they give it strength.

bone marrow transplant: a procedure that replaces bone marrow that has been destroyed by cancer treatment; it is also used to treat certain types of cancers and blood disorders. Also called *hematopoietic stem cell transplantation.*

bone meal or **powdered bone:** crushed or ground bone preparations intended to supply calcium to the diet. Calcium from bone is not well absorbed and is often contaminated with toxic minerals such as arsenic, mercury, lead, and cadmium.

bottled water: drinking water sold in bottles.

botulism (BOT-chew-lism): an often fatal foodborne illness caused by the ingestion of foods containing a toxin produced by bacteria that grow without oxygen.

Bowman's (BOE-minz) **capsule:** a cuplike component of the nephron that surrounds the glomerulus and collects the filtrate that is passed to the tubules.

branched-chain amino acids: the essential amino acids leucine, isoleucine, and valine, which are present in large amounts in skeletal muscle tissue; falsely promoted as fuel for exercising muscles.

breast milk bank: a service that collects, screens, processes, and distributes donated human milk.

bronchi (BRON-key), **bronchioles** (BRON-key-oles): the main airways of the lungs. The singular form of bronchi is *bronchus.*

brown adipose tissue: masses of specialized fat cells packed with pigmented mitochondria that produce heat instead of ATP.

brown sugar: refined white sugar crystals to which manufacturers have added molasses syrup with natural flavor and color; 91 to 96% pure sucrose.

buffalo hump: the accumulation of fatty tissue at the base of the neck.

bulimia (byoo-LEEM-ee-ah) **nervosa:** an eating disorder characterized by repeated episodes of binge eating usually followed by self-induced vomiting, misuse of laxatives or diuretics, fasting, or excessive exercise.

C

C-reactive protein: an acute-phase protein released from the liver during acute inflammation or stress.

calcitonin (KAL-seh-TOE-nin): a hormone secreted by the thyroid gland that regulates blood calcium by lowering it when levels rise too high.

calcium: the most abundant mineral in the body; found primarily in the body's bones and teeth.

calcium-binding protein: a protein in the intestinal cells, made with the help of vitamin D, that facilitates calcium absorption.

calcium rigor: hardness or stiffness of the muscles caused by high blood calcium concentrations.

calcium tetany (TET-ah-nee): intermittent spasm of the extremities due to nervous and muscular excitability caused by low blood calcium concentrations.

calories: units by which energy is measured. Food energy is measured in **kilocalories** (1000 calories equal 1 kilocalorie), abbreviated **kcalories** or **kcal.** One kcalorie is the amount of heat necessary to raise the temperature of 1 kilogram (kg) of water 1°C. The scientific use of the term *kcalorie* is the same as the popular use of the term *calorie.*

cancer cachexia (ka-KEK-see-ah): a wasting syndrome associated with cancer that is characterized by anorexia, muscle wasting, weight loss, and fatigue.

cancers: malignant growths or tumors that result from abnormal and uncontrolled cell division.

capillaries (CAP-ill-aries): small vessels that branch from an artery. Capillaries connect arteries to veins. Exchange of oxygen, nutrients, and waste materials takes place across capillary walls.

carbohydrate-to-insulin ratio: the amount of carbohydrate that can be handled per unit of insulin. On average, every 15 g of carbohydrate requires about 1 unit of rapid- or short-acting insulin.

carbohydrates: compounds composed of carbon, oxygen, and hydrogen arranged as monosaccharides or multiples of monosaccharides. Most, but not all, carbohydrates have a ratio of one carbon molecule to one water molecule: $(CH_2O)_n$.

carbonated water: water that contains carbon dioxide gas, either naturally occurring or added, that causes bubbles to form in it; also called *bubbling* or *sparkling water.* Seltzer, soda, and tonic waters are legally soft drinks and are not regulated as water.

carbonic acid: a compound with the formula H_2CO_3 that results from the combination of carbon dioxide (CO_2) and water (H_2O); of particular importance in maintaining the body's acid-base balance.

carcinogenesis (CAR-sin-oh-JEN-eh-sis): the process of cancer development.

carcinogens (CAR-sin-oh-jenz or car-SIN-oh-jenz): substances that can cause cancer (the adjective is *carcinogenic*).

cardiac cachexia: the severe muscle wasting and weight loss that accompany heart failure.

cardiac output: the volume of blood pumped by the heart within a specified period of time.

cardiopulmonary resuscitation (CPR): life-sustaining treatment that supplies oxygen and restores a person's ability to breathe and pump blood.

cardiovascular disease (CVD): a general term for all diseases of the heart and blood vessels. Atherosclerosis is the main cause of CVD. When the arteries that carry blood to the heart muscle become blocked, the heart suffers damage known as **coronary heart disease (CHD).**

carnitine (CAR-neh-teen): a nonessential, nonprotein amino acid made in the body from lysine that helps transport fatty acids across the mitochondrial membrane.

carotenoids (kah-ROT-eh-noyds): pigments commonly found in plants and animals, some of which have vitamin A activity. The carotenoid with the greatest vitamin A activity is beta-carotene.

carpal tunnel syndrome: a pinched nerve at the wrist, causing pain or numbness in the hand. It is often caused by repetitive motion of the wrist.

catabolism (ca-TAB-o-lism): reactions in which large molecules are broken down to smaller ones. Catabolic reactions release energy.

catalyst (CAT-uh-list): a compound that facilitates chemical reactions without itself being changed in the process.

cataracts (KAT-ah-rakts): thickenings of the eye lenses that impair vision and can lead to blindness.

cathartic (ka-THAR-tik): a strong laxative.

catheter: a thin tube placed within a narrow lumen (such as a blood vessel) or body cavity; can be used to infuse or withdraw fluids or keep a passage open.

cations (CAT-eye-uns): positively charged ions.

celiac (SEE-lee-ack) **disease:** a condition characterized by an abnormal immune reaction to wheat gluten that causes severe intestinal damage and nutrient malabsorption; also called *gluten-sensitive enteropathy* or *celiac sprue.*

cell: the basic structural unit of all living things.

cell differentiation (DIF-er-EN-she-AY-shun): the process by which immature cells develop specific functions different from those of the original that are characteristic of their mature cell type.

cell membrane: the thin layer of tissue that surrounds the cell and encloses its contents; made primarily of lipid and protein.

cell-mediated immunity: immunity conferred by T cells and macrophages.

cellulite (SELL-you-light or SELL-you-leet): supposedly, a lumpy form of fat; actually, a fraud. Fatty areas of the body may appear lumpy when the strands of connective tissue that attach the skin to underlying muscles pull tight where the fat is thick. The fat itself is the same as fat anywhere else in the body. If the fat in these areas is lost, the lumpy appearance disappears.

central nervous system: the central part of the nervous system; the brain and spinal cord.

central obesity: excess fat around the trunk of the body; also called **abdominal fat** or **upper-body fat.**

central veins: large-diameter veins located close to the heart.

Certified Diabetes Educator (CDE): a health care professional who specializes in diabetes management education. Certification is obtained from the National Certification Board for Diabetes Educators.

certified nutritionist or **certified nutritional consultant** or **certified nutrition therapist:** a person who has been granted a document declaring his or her authority as a nutrition professional; see also *nutritionist*.

cesarean section: a surgically assisted birth involving removal of the fetus by an incision into the uterus, usually by way of the abdominal wall.

chelate (KEY-late): a substance that can grasp the positive ions of a mineral.

chemotherapy: the use of drugs to arrest or destroy cancer cells; these drugs are called *antineoplastic agents.*

chiropractic (KYE-roh-PRAK-tic): an alternative medical system based on the unproven theory that spinal manipulation can restore health.

chloride (KLO-ride): the major anion in the extracellular fluids of the body. Chloride is the ionic form of chlorine, Cl_2. See Appendix B for a description of the chlorine-to-chloride conversion.

chlorophyll (KLO-row-fil): the green pigment of plants, which absorbs light and transfers the energy to other molecules, thereby initiating photosynthesis.

cholecystectomy (KOH-leh-sis-TEK-toe-mee): surgical removal of the gallbladder.

cholecystitis (KOH-leh-sih-STY-tis): inflammation of the gallbladder, usually caused by obstruction of the cystic duct by gallstones.

cholecystokinin (COAL-ee-SIS-toe-KINE-in), or **CCK:** a hormone produced by cells of the intestinal wall. Target organ: the gallbladder. Response: release of bile and slowing of GI motility.

cholelithiasis (KOH-leh-lih-THIGH-ah-sis): formation of gallstones.

cholesterol (koh-LESS-ter-ol): one of the sterols containing a four ring carbon structure with a carbon side chain.

cholesterol-free: less than 2 mg cholesterol per serving and 2 g or less saturated fat and *trans* fat combined per serving.

choline (KOH-leen): a nitrogen-containing compound found in foods and made in the body from the amino acid methionine. Choline is part of the phospholipid lecithin and the neurotransmitter acetylcholine.

chromosomes: structures within the nucleus of a cell made of DNA and associated proteins. Human beings have 46 chromosomes in 23 pairs. Each chromosome has many genes.

chronic bronchitis (bron-KYE-tis): a lung disorder characterized by persistent inflammation and excessive secretions of mucus in the main airways of the lungs; diagnosis is based on the presence of a chronic, productive cough for at least three months of the year for two successive years.

chronic diseases: diseases characterized by a slow progression and long duration. Examples include heart disease, cancer, and diabetes.

chronic kidney disease: a kidney disease characterized by gradual, irreversible deterioration of the kidneys; also called **chronic renal failure.**

chronic obstructive pulmonary disease (COPD): a group of lung diseases characterized by persistent obstructed airflow through the lungs and airways; includes chronic bronchitis and emphysema.

chronic PEM: protein-energy malnutrition caused by long-term food deprivation; characterized in children by short height for age (stunting).

chronological age: a person's age in years from his or her date of birth.

chylomicrons (kye-lo-MY-cronz): the class of lipoproteins that transport lipids from the intestinal cells to the rest of the body.

chyme (KIME): the semiliquid mass of partly digested food expelled by the stomach into the duodenum.

cirrhosis (sih-ROE-sis): an advanced stage of liver disease in which extensive scarring replaces healthy liver tissue, causing impaired liver function and liver failure; often associated with alcoholism.

claudication (CLAW-dih-KAY-shun): pain in the legs while walking; usually due to an inadequate supply of blood to muscles.

clear liquid diet: a diet that consists of foods that are liquid at body temperature, require minimal digestion, and contribute limited residue (undigested material) in the colon.

clinically severe obesity: a BMI of 40 or greater or a BMI of 35 or greater with additional medical problems. A less preferred term used to describe the same condition is *morbid obesity.*

closed feeding system: a delivery system in which the formula comes prepackaged in a container that is ready to be attached to the feeding tube for administration.

CoA (coh-AY): coenzyme A; the coenzyme derived from the B vitamin pantothenic acid and central to energy metabolism.

coenzymes: complex organic molecules that work with enzymes to facilitate the enzymes' activity. Many coenzymes have B vitamins as part of their structures (Figure 10-1 on p. 327 in Chapter 10 illustrates coenzyme action).

colectomy: removal of a portion or all of the colon.

colitis (ko-LYE-tis): inflammation of the colon.

collagen (KOL-ah-jen): the protein from which connective tissues such as scars, tendons, ligaments, and the foundations of bones and teeth are made.

collaterals: blood vessels that enlarge to allow an alternative pathway for diverted blood.

collecting duct: the last portion of a nephron's tubule, where the final concentration of urine occurs. One collecting duct is shared by several nephrons.

colonic irrigation: the popular, but potentially harmful practice of "washing" the large intestine with a powerful enema machine.

colostomy (co-LAH-stoe-me): a surgical procedure that creates a stoma using a section of the colon.

colostrum (ko-LAHS-trum): a milklike secretion from the breast, present during the first day or so after delivery before milk appears; rich in protective factors.

complement: a group of plasma proteins that assist the activities of antibodies.

complementary and alternative medicine (CAM): diverse medical and health care systems, practices, and products that currently are not considered part of conventional medicine; also called *unconventional* or *unorthodox therapies*.

- *Complementary medicine* refers to unconventional therapies that are used *in addition to,* and not simply as a replacement for, conventional medicine.
- *Alternative medicine* refers to unconventional therapies that are used *in place of* conventional medicine.

complementary proteins: two or more dietary proteins whose amino acid assortments complement each other in such a way that the essential amino acids missing from one are supplied by the other.

complex carbohydrates (starches and fibers): polysaccharides composed of straight or branched chains of monosaccharides.

compound: a substance composed of two or more different atoms—for example, water (H_2O).

conception: the union of the male sperm and the female ovum; fertilization.

condensation: a chemical reaction in which two reactants combine to yield a larger product.

conditionally essential amino acid: an amino acid that is normally nonessential, but must be supplied by the diet in special circumstances when the need for it exceeds the body's ability to produce it.

confectioners' sugar: finely powdered sucrose, 99.9% pure.

congregate meals: nutrition programs that provide food for the elderly in conveniently located settings such as community centers.

conjugated linoleic acid: a collective term for several fatty acids that have the same chemical formula as linoleic acid (18 carbons, two double bonds) but with different configurations.

constipation: the condition of having infrequent or difficult bowel movements.

contamination iron: iron found in foods as the result of contamination by inorganic iron salts from iron cookware, iron-containing soils, and the like.

continuous ambulatory peritoneal dialysis (CAPD): the most common method of peritoneal dialysis; involves frequent exchanges of dialysate, which remains in the peritoneal cavity throughout the day.

continuous feedings: slow delivery of formula at a constant rate over an 8- to 24-hour period.

continuous parenteral nutrition: continuous administration of parenteral solutions over a 24-hour period.

continuous renal replacement therapy (CRRT): a slow, continuous method of removing solutes and/or fluids from blood by gently pumping blood across a filtration membrane over a prolonged time period.

control group: a group of individuals similar in all possible respects to the experimental group except for the treatment. Ideally, the control group receives a placebo while the experimental group receives a real treatment.

conventional medicine: diagnosis and treatment of diseases as practiced by a doctor of medicine (M.D.) or doctor of osteopathy (D.O.) and assisted by allied health professionals such as registered nurses, pharmacists, and physical therapists; also called *Western, mainstream,* or *orthodox medicine.*

Cori cycle: the path from muscle glycogen to glucose to pyruvate to lactate (which travels to the liver) to glucose (which can travel back to the muscle) to glycogen; named after the scientist who elucidated this pathway.

corn sweeteners: corn syrup and sugars derived from corn.

corn syrup: a syrup made from cornstarch that has been treated with acid, high temperatures, and enzymes that produce glucose, maltose, and dextrins. See also *high-fructose corn syrup (HFCS).*

cornea (KOR-nee-uh): the transparent membrane covering the outside of the eye.

coronary heart disease (CHD): a chronic, progressive disease characterized by obstructed blood flow in the coronary arteries; also called *coronary artery disease.*

correlation (CORE-ee-LAY-shun): the simultaneous increase, decrease, or change in two variables. If A increases as B increases, or if A decreases as B decreases, the correlation is **positive.** (This does not mean that A causes B or vice versa.) If A increases as B decreases, or if A decreases as B increases, the correlation is **negative.** (This does not mean that A prevents B or vice versa.) Some third factor may account for both A and B.

correspondence schools: schools that offer courses and degrees by mail. Some correspondence schools are accredited; others are not.

cortical bone: the very dense bone tissue that forms the outer shell surrounding trabecular bone and comprises the shaft of a long bone.

coupled reactions: pairs of chemical reactions in which some of the energy released from the breakdown of one compound is used to create a bond in the formation of another compound.

covert (KOH-vert): hidden, as if under covers.

cretinism (CREE-tin-ism): a congenital disease characterized by mental and physical retardation and commonly caused by maternal iodine deficiency during pregnancy.

critical pathways: coordinated programs of treatment that merge the care plans of different health practitioners; also called *clinical pathways.*

critical periods: finite periods during development in which certain events occur that will have irreversible effects on later developmen-

tal stages; usually a period of rapid cell division.

Crohn's disease: an inflammatory bowel disease that usually occurs in the lower portion of the small intestine and the colon. Inflammation may pervade the entire intestinal wall.

cross-contamination: the contamination of food by bacteria that occurs when the food comes into contact with surfaces previously touched by raw meat, poultry, or seafood.

cross-reactivity: an antibody reaction involving an antigen other than the one that induced the antibody's formation.

cryptosporidiosis (KRIP-toe-spor-ih-dee-OH-sis): a foodborne illness caused by the parasite *Cryptosporidium parvum.*

crypts (KRIPTS): tubular glands that lie between the intestinal villi and secrete intestinal juices into the small intestine.

cyanosis (sigh-ah-NOH-sis): a bluish cast in the skin due to the color of deoxygenated hemoglobin. Cyanosis is most evident in individuals with lighter, thinner skin; it is mostly seen on lips, cheeks, and ears and under the nails.

cyclamate (SIGH-kla-mate): an artificial sweetener that is being considered for approval in the United States and is available in Canada as a tabletop sweetener, but not as an additive.

cyclic parenteral nutrition: administration of a parenteral solution over a 10- to 16-hour period.

cystic fibrosis: an inherited disorder that affects the transport of chloride across epithelial cell membranes; primarily affects the gastrointestinal and respiratory systems.

cystinuria (SIS-tin-NOO-ree-ah): an inherited disorder characterized by elevated urinary excretion of several amino acids, including cystine.

cytokines (SIGH-toe-kines): signaling proteins produced by the body's cells; those produced by white blood cells regulate immune cell development and immune responses.

cytoplasm (SIGH-toh-plazm): the cell contents, except for the nucleus.

cytosol: the fluid of cytoplasm; contains water, ions, nutrients, and enzymes.

D

Daily Values (DV): reference values developed by the FDA specifically for use on food labels.

dawn phenomenon: morning hyperglycemia that is caused by the early-morning release of growth hormone, which counteracts insulin's glucose-lowering effects.

deamination (dee-AM-ih-NAY-shun): removal of the amino (NH_2) group from a compound such as an amino acid.

debridement: the surgical removal of dead, damaged, or contaminated tissue resulting from burns or wounds; helps to prevent infection and hasten healing.

decision-making capacity: the ability to understand pertinent information and make appropriate decisions; known as *decision-making competency* within the legal system.

defecate (DEF-uh-cate): to move the bowels and eliminate waste.

defibrillation: life-sustaining treatment in which an electronic device is used to shock the heart and reestablish a pattern of normal contractions. Defibrillation is used when the heart has arrhythmias or has experienced cardiac arrest.

deficient: the amount of a nutrient below which almost all healthy people can be expected, over time, to experience deficiency symptoms.

dehydration: the condition in which body water output exceeds water input. Symptoms include thirst, dry skin and mucous membranes, rapid heartbeat, low blood pressure, and weakness.

denaturation (dee-NAY-chur-AY-shun): the change in a protein's shape and consequent loss of its function brought about by heat, agitation, acid, base, alcohol, heavy metals, or other agents.

dental calculus: mineralized dental plaque, often associated with inflammation and bleeding.

dental caries: decay of teeth.

dental plaque: a gummy mass of bacteria that grows on teeth and can lead to dental caries and gum disease.

dermatitis herpetiformis (DERM-ah-TYE-tis HER-peh-tih-FOR-mis): a gluten-sensitive disorder characterized by a severe skin rash.

dermis: the connective tissue layer underneath the epidermis that contains the skin's blood vessels and nerves.

dextrose: an older name for glucose.

diabetes (DYE-ah-BEE-teez) **mellitus:** a group of metabolic disorders characterized by hyperglycemia resulting from insufficient or ineffective insulin.

diabetic coma: a coma that occurs in uncontrolled diabetes; may be due to diabetic ketoacidosis, the hyperosmolar hyperglycemic state, or severe hypoglycemia.

diabetic nephropathy (neh-FRAH-pah-thee): damage to the kidneys that results from long-term diabetes.

diabetic neuropathy (nur-RAH-pah-thee): complications of diabetes that cause damage to nerves.

diabetic retinopathy (REH-tih-NAH-pah-thee): retinal damage that results from long-term diabetes.

dialysate (dye-AL-ih-sate): the solution used in dialysis to draw wastes and fluids from the blood.

dialysis (dye-AH-lih-sis): a treatment that removes wastes and excess fluid from the blood after the kidneys have stopped functioning. The most common types of dialysis are *hemodialysis* and *peritoneal dialysis* (see Highlight 28).

dialyzer (DYE-ah-LYE-zer): a machine used in hemodialysis to filter the blood; also called an *artificial kidney.*

diarrhea: the frequent passage of watery bowel movements.

diet: the foods and beverages a person eats and drinks.

diet manual: a resource that specifies the foods allowed and restricted in modified diets and provides sample menus.

diet orders: specific instructions regarding dietary management; also called *diet prescriptions.*

dietary antioxidants: substances typically found in foods that significantly decrease the adverse effects of free radicals on normal functions in the body.

dietary fibers: in plant foods, the *nonstarch polysaccharides* that are not digested by human digestive enzymes, although some are digested by GI tract bacteria. Dietary fibers include cellulose, hemicelluloses, pectins, gums, and mucilages and the nonpolysaccharides lignins, cutins, and tannins.

dietary folate equivalents (DFE): the amount of folate available to the body from naturally occurring sources, fortified foods, and supplements, accounting for differences in the bioavailability from each source.

Dietary Reference Intakes (DRI): a set of nutrient intake values for healthy people in the United States and Canada. These values are used for planning and assessing diets and include:
- Estimated Average Requirements (EAR)
- Recommended Dietary Allowance (RDA)
- Adequate Intakes (AI)
- Tolerable Upper Intake Levels (UL)

dietetic technician: a person who has completed a minimum of an associate's degree from an accredited university or college and an approved dietetic technician program that includes a supervised practice experience. See also *dietetic technician, registered (DTR).*

dietetic technician, registered (DTR): a dietetic technician who has passed a national examination and maintains registration through continuing professional education.

dietitian: a person trained in nutrition, food science, and diet planning. See also *registered dietitian.*

diffusion: movement of solutes from an area of high concentration to one of low concentration.

digestion: the process by which food is broken down into absorbable units.

digestive enzymes: proteins found in digestive juices that act on food substances, causing them to break down into simpler compounds.

digestive system: all the organs and glands associated with the ingestion and digestion of food.

dipeptide (dye-PEP-tide): two amino acids bonded together.

disaccharides (dye-SACK-uh-rides): pairs of monosaccharides linked together. See Appendix C for the chemical structures of the disaccharides.

disclosure: the act of revealing pertinent information. For example, clinicians should accurately describe proposed tests and procedures, their benefits and risks, and alternative approaches.

discretionary kcalorie allowance: the kcalories remaining in a person's energy allowance after consuming enough nutrient-dense foods to meet all nutrient needs for a day.

disordered eating: eating behaviors that are neither normal nor healthy, including restrained eating, fasting, binge eating, and purging.

dissociates (dis-SO-see-aites): physically separates.

distilled liquor or **hard liquor:** an alcoholic beverage made by fermenting and distilling grains; sometimes called *distilled spirits.*

distilled water: water that has been vaporized and recondensed, leaving it free of dissolved minerals.

distributive justice: the equitable distribution of resources.

diuresis (DYE-uh-REE-sis): increased urine production.

diverticula (dye-ver-TIC-you-la): sacs or pouches that develop in the weakened areas of the intestinal wall (like bulges in an inner tube where the tire wall is weak).

diverticulitis (DYE-ver-tic-you-LYE-tis): infected or inflamed diverticula.

diverticulosis (DYE-ver-tic-you-LOH-sis): the condition of having diverticula. About one in every six people in Western countries develops diverticulosis in middle or later life.

DNA (deoxyribonucleic acid): the double helix molecules of which genes are made.

do-not-resuscitate (DNR) order: a request by a patient or surrogate to withhold cardiopulmonary resuscitation.

docosahexaenoic (DOE-cossa-HEXA-ee-NO-ick) **acid (DHA):** an omega-3 polyunsaturated fatty acid with 22 carbons and six double bonds; present in fish and synthesized in limited amounts in the body from linolenic acid.

dolomite: a compound of minerals (calcium magnesium carbonate) found in limestone and marble. Dolomite is powdered and is sold as a calcium-magnesium supplement. However, it may be contaminated with toxic minerals, is not well absorbed, and interacts adversely with absorption of other esssential minerals.

double-blind experiment: an experiment in which neither the subjects nor the researchers know which subjects are members of the experimental group and which are serving as control subjects, until after the experiment is over.

Down syndrome: a genetic abnormality that causes mental retardation, short stature, and flattened facial features.

drink: a dose of any alcoholic beverage that delivers ½ oz of pure ethanol:
- 5 oz of wine
- 10 oz of wine cooler
- 12 oz of beer
- 1½ oz of hard liquor (80 proof whiskey, scotch, rum, or vodka)

drug: a substance that can modify one or more of the body's functions.

DTR: *see dietetic technician, registered.*

dumping syndrome: symptoms that result from the rapid emptying of an osmotic load from the stomach into the small intestine. Early symptoms include nausea, abdominal cramps, weakness, and diarrhea; later symptoms are those of hypoglycemia.

duodenum (doo-oh-DEEN-um, or doo-ODD-num): the top portion of the small intestine (about "12 fingers' breadth" long in ancient terminology).

durable power of attorney: a legal document (sometimes called a *health care proxy*) that gives legal authority to another (a *health care agent*) to make medical decisions in the event of incapacitation.

dysentery (DISS-en-terry): an infection of the digestive tract that causes diarrhea.

dyspepsia: a feeling of pain, bloating, or discomfort in the upper abdominal area, often called **indigestion**; a symptom of illness rather than a disease itself.

dysphagia (dis-FAY-jah): difficulty in swallowing.

dyspnea (DISP-nee-ah): shortness of breath.

E

eating disorders: disturbances in eating behavior that jeopardize a person's physical or psychological health.

eclampsia (eh-KLAMP-see-ah): a severe stage of preeclampsia characterized by convulsions.

edema (eh-DEEM-uh): the swelling of body tissue caused by excessive amounts of fluid in the interstitial spaces; seen in protein deficiency (among other conditions).

eicosanoids (eye-COSS-uh-noyds): derivatives of 20-carbon fatty acids; biologically active compounds that help to regulate blood pressure, blood clotting, and other body functions. They include *prostaglandins* (PROS-tah-GLAND-ins), *thromboxanes* (throm-BOX-ains), and *leukotrienes* (LOO-ko-TRY-eens).

eicosapentaenoic (EYE-cossa-PENTA-ee-NO-ick) **acid (EPA):** an omega-3 polyunsaturated fatty acid with 20 carbons and five double bonds; present in fish and synthesized in limited amounts in the body from linolenic acid.

electrolyte solutions: solutions that can conduct electricity.

electrolytes: salts that dissolve in water and dissociate into charged particles called ions.

electron transport chain: the final pathway in energy metabolism that transports electrons from hydrogen to oxygen and captures the energy released in the bonds of ATP.

element: a substance composed of atoms that are alike—for example, iron (Fe).

elemental formulas: enteral formulas that contain carbohydrates and proteins that are partially or fully hydrolyzed; also called *hydrolyzed, chemically defined,* or *monomeric formulas.*

embolism (EM-boh-lizm): the obstruction of a blood vessel by an embolus, causing sudden tissue death.

embolus (EM-boh-lus): an abnormal particle, such as a blood clot or air bubble, that travels in the blood.

embryo (EM-bree-oh): the developing infant from two to eight weeks after conception.

emergency shelters: facilities that are used to provide temporary housing.

emetic (em-ETT-ic): an agent that causes vomiting.

emphysema (EM-fih-ZEE-mah): a progressive lung condition characterized by the breakdown of the lungs' elastic structure and destruction of the walls of the bronchioles and alveoli, reducing the surface area involved in respiration.

empty-kcalorie foods: a popular term used to denote foods that contribute energy but lack protein, vitamins, and minerals.

emulsifier (ee-MUL-sih-fire): a substance with both water-soluble and fat-soluble portions that promotes the mixing of oils and fats in a watery solution.

end-stage renal disease (ESRD): an advanced stage of chronic kidney disease in which dialysis or a kidney transplant is necessary to sustain life.

endoplasmic reticulum (en-doh-PLAZ-mic reh-TIC-you-lum): a complex network of intracellular membranes. The rough endoplasmic reticulum is dotted with ribosomes, where protein synthesis takes place. The smooth endoplasmic reticulum bears no ribosomes.

endothelial cells: the type of cells that line the blood vessels, lymphatic vessels, and body cavities.

enemas: solutions inserted into the rectum and colon to stimulate a bowel movement and empty the lower large intestine.

energy: the capacity to do work. The energy in food is chemical energy. The body can convert this chemical energy to mechanical, electrical, or heat energy.

energy density: a measure of the energy a food provides relative to the amount of food (kcalories per gram).

energy-yielding nutrients: the nutrients that break down to yield energy the body can use:
- Carbohydrate
- Fat
- Protein

enriched: the addition to a food of nutrients that were lost during processing so that the food will meet a specified standard.

enteral (EN-ter-al) **nutrition:** the provision of nutrients using the GI tract, including the use of tube feedings and oral diets.

enteric coated: refers to medications or enzyme preparations that can withstand gastric acidity and dissolve only at a higher pH.

enteropancreatic (EN-ter-oh-PAN-kree-AT-ik) **circulation:** the circulatory route from the pancreas to the intestine and back to the pancreas.

enterostomy (EN-ter-AH-stoe-mee): an opening into the GI tract through which a feeding tube can be passed.

enzymes: proteins that facilitate chemical reactions without being changed in the process; protein catalysts.

epidemic (ep-ih-DEM-ick): the appearance of a disease (usually infectious) or condition that attacks many people at the same time in the same region.

epidermis (eh-pih-DER-miss): the outer layer of the skin.

epigenetics: the study of heritable changes in gene function that occur without a change in the DNA sequence.

epiglottis (epp-ih-GLOTT-iss): cartilage in the throat that guards the entrance to the trachea and prevents fluid or food from entering it when a person swallows.

epinephrine (EP-ih-NEFF-rin): a hormone of the adrenal gland that modulates the stress response; formerly called **adrenaline**. When administered by injection, epinephrine counteracts anaphylactic shock by opening the airways and maintaining heartbeat and blood pressure.

epithelial (ep-i-THEE-lee-ul) **cells:** cells on the surface of the skin and mucous membranes.

epithelial tissue: the layer of the body that serves as a selective barrier between the body's interior and the environment. (Examples are the cornea of the eyes, the skin, the respiratory lining of the lungs, and the lining of the digestive tract.)

erosive gastritis: erosion of the gastric mucosa, characterized by tissue destruction, ulcers, and hemorrhaging; often caused by the toxic effects of chemical substances or radiation treatment.

erythrocyte (eh-RITH-ro-cite) **hemolysis** (he-MOLL-uh-sis): the breaking open of red blood cells (erythrocytes); a symptom of vitamin E–deficiency disease in human beings.

erythrocyte protoporphyrin (PRO-toe-PORE-fe-rin): a precursor to hemoglobin.

erythropoiesis (eh-RIH-throh-poy-EE-sis): production of red blood cells within the bone marrow.

erythropoietin (eh-RITH-ro-POY-eh-tin): a hormone made by the kidneys that stimulates red blood cell production.

esophageal (eh-SOF-ah-JEE-al): involving the esophagus.

esophageal dysphagia: an inability to move food through the esophagus; usually caused by an obstruction or a motility disorder.

esophageal (ee-SOF-ah-GEE-al) **sphincter:** a sphincter muscle at the upper or lower end of the esophagus. The lower esophageal sphincter is also called the *cardiac sphincter.*

esophagus (ee-SOFF-ah-gus): the food pipe; the conduit from the mouth to the stomach.

essential amino acids: amino acids that the body cannot synthesize in amounts sufficient to meet physiological needs (see Table 6-1 on p. 182).

essential fatty acids: fatty acids needed by the body but not made by it in amounts sufficient to meet physiological needs.

essential nutrients: nutrients a person must obtain from food because the body cannot make them for itself in sufficient quantity to meet physiological needs; also called **indispensable nutrients.** About 40 nutrients are currently known to be essential for human beings.

Estimated Average Requirement (EAR): the average daily amount of a nutrient that will maintain a specific biochemical or physiological function in half the healthy people of a given age and gender group.

Estimated Energy Requirement (EER): the average dietary energy intake that maintains energy balance and good health in a person of a given age, gender, weight, height, and level of physical activity.

estrogens: hormones responsible for the menstrual cycle and other female characteristics.

ethanol: a particular type of alcohol found in beer, wine, and distilled liquor; also called *ethyl alcohol* (see Figure H7-1). Ethanol is the most widely used—and abused—drug in our society. It is also the only legal, nonprescription drug that produces euphoria.

ethical: in accordance with accepted principles of right and wrong.

exchange lists: diet-planning tools that organize foods by their proportions of carbohydrate, fat, and protein. Foods on any single list can be used interchangeably.

exocrine: pertains to external secretions, such as those of the mucous membranes or the skin. Opposite of endocrine, which pertains to hormonal secretions into the blood.

experimental group: a group of individuals similar in all possible respects to the control group except for the treatment. The experimental group receives the real treatment.

extra lean: less than 5 g of fat, 2 g of saturated fat and *trans* fat combined, and 95 mg of cholesterol per serving and per 100 g of meat, poultry, and seafood.

extracellular fluid: fluid outside the cells. Extracellular fluid includes two main components—the interstitial fluid and plasma. Extracellular fluid accounts for approximately one-third of the body's water.

F

fad diets: popular eating plans that promise quick weight loss. Most fad diets severely limit certain foods or overemphasize others (for example, never eat potatoes or pasta or eat cabbage soup daily).

faith healing: the use of prayer or belief in divine intervention to promote healing.

false negative: a test result indicating that a condition is not present (negative) when in fact it is present (therefore false).

false positive: a test result indicating that a condition is present (positive) when in fact it is not (therefore false).

fat replacers: ingredients that replace some or all of the functions of fat and may or may not provide energy.

fat-free: less than 0.5 g of fat per serving (and no added fat or oil); synonyms include "zero-fat," "no-fat," and "nonfat."

fats: lipids that are solid at room temperature (77°F or 25°C).

fatty acid: an organic compound composed of a carbon chain with hydrogens attached and an acid group (COOH) at one end and a methyl group (CH3) at the other end.

fatty acid oxidation: the metabolic breakdown of fatty acids to acetyl CoA; also called **beta oxidation.**

fatty liver: an early stage of liver deterioration seen in several diseases, including kwashiorkor and alcoholic liver disease. Fatty liver is characterized by an accumulation of fat in the liver cells.

fatty streaks: accumulations of cholesterol and other lipids along the walls of the arteries.

FDA (Food and Drug Administration): a part of the Department of Health and Human Services' Public Health Service that is responsible for ensuring the safety and wholesomeness of all dietary supplements and food processed and sold in interstate commerce except meat, poultry, and eggs (which are under the jurisdiction of the USDA); inspecting food plants and imported foods; and setting standards for food composition and product labeling.

female athlete triad: a potentially fatal combination of three medical problems—disordered eating, amenorrhea, and osteoporosis.

fermentable: the extent to which bacteria in the GI tract can break down fibers to fragments that the body can use.

ferritin (FAIR-ih-tin): the iron storage protein.

fertility: the capacity of a woman to produce a normal ovum periodically and of a man to produce normal sperm; the ability to reproduce.

fetal alcohol spectrum disorder: a range of physical, behavioral, and cognitive abnormalities caused by prenatal alcohol exposure.

fetal alcohol syndrome (FAS): a cluster of physical, behavioral, and cognitive abnormalities associated with prenatal alcohol exposure, including facial malformations, growth retardation, and central nervous disorders.

fetal programming: the influence of substances during fetal growth on the development of diseases in later life.

fetus (FEET-us): the developing infant from eight weeks after conception until term.

fibrinogen (fye-BRIN-oh-jen): a liver protein that promotes blood clot formation.

fibrocystic (FYE-bro-SIS-tik) **breast disease:** a harmless condition in which the breasts develop lumps, sometimes associated with caffeine consumption. In some, it responds to abstinence from caffeine; in others, it can be treated with vitamin E.

fibrosis (fye-BROH-sis): an intermediate stage of liver deterioration seen in several diseases, including viral hepatitis and alcoholic liver disease. In fibrosis, the liver cells lose their function and assume the characteristics of connective tissue cells (fibers).

filtered water: water treated by filtration, usually through *activated carbon filters* that reduce the lead in tap water, or by *reverse osmosis* units that force pressurized water across a membrane removing lead, arsenic, and some microorganisms from tap water.

filtrate: the substances that pass through the glomerulus and travel through the nephron's tubules, eventually forming urine.

fistulas (FIST-you-luz): abnormal passages between organs or tissues (or between an internal organ and the body's surface) that permit the passage of fluids or secretions.

flatulence: the condition of having excessive intestinal gas, which causes abdominal discomfort.

flavonoids (FLAY-von-oyds): yellow pigments in foods; phytochemicals that may exert physiological effects on the body.

flaxseeds: the small brown seeds of the flax plant; valued as a source of linseed oil, fiber, and omega-3 fatty acids.

flora: the bacteria that normally reside in a person's body.

fluid balance: maintenance of the proper types and amounts of fluid in each compartment of the body fluids (see also Chapter 12).

fluorapatite (floor-APP-uh-tite): the stabilized form of bone and tooth crystal, in which fluoride has replaced the hydroxyl groups of hydroxyapatite.

fluorosis (floor-OH-sis): discoloration and pitting of tooth enamel caused by excess fluoride during tooth development.

foam cells: swollen cells in the artery wall that accumulate lipids.

folate (FOLE-ate): a B vitamin; also known as folic acid, folacin, or pteroylglutamic (tare-o-EEL-glue-TAM-ick) acid (PGA). The coenzyme forms are **DHF (dihydrofolate)** and **THF (tetrahydrofolate).**

follicle-stimulating hormone (FSH): a hormone that stimulates maturation of the ovarian follicles in females and the production of sperm in males. (The ovarian follicles are part of the female reproductive system where the eggs are produced.) The release of FSH is mediated by *follicle-stimulating hormone releasing hormone (FSH–RH).*

food allergy: an adverse reaction to food that involves an immune response; also called **food-hypersensitivity reaction.**

food and symptom diary: a food record kept by a patient to determine the cause of an adverse reaction; includes the specific foods and beverages consumed, symptoms experienced, and the timing of meals and symptom onset.

food aversions: strong desires to avoid particular foods.

food bank: a facility that collects and distributes food donations to authorized organizations feeding the hungry.

food cravings: strong desires to eat particular foods.

food frequency questionnaire: a survey of foods routinely consumed. Some questionnaires ask about the types of food eaten and yield only qualitative information; others include questions about portions consumed and yield semiquantitative data as well.

food group plans: diet-planning tools that sort foods into groups based on nutrient content and then specify that people should eat certain amounts of foods from each group.

food insecurity: limited or uncertain access to foods of sufficient quality or quantity to sustain a healthy and active life.

food insufficiency: an inadequate amount of food due to a lack of resources.

food intolerances: adverse reactions to foods that do not involve the immune system.

food pantries: programs that provide groceries to be prepared and eaten at home.

food poverty: hunger resulting from inadequate access to available food for various reasons, including inadequate resources, political obstacles, social disruptions, poor weather conditions, and lack of transportation.

food record: a detailed log of food eaten during a specified time period, usually several days; also called a food diary. A food record may also include information regarding disease symptoms, physical activity, and medication use.

food recovery: collecting wholesome food for distribution to low-income people who are hungry. Four common methods of food recovery are:

- *field gleaning:* collecting crops from fields that either have already been harvested or are not profitable to harvest.
- *nonperishable food collection:* collecting processed foods from wholesalers and markets.
- *perishable food rescue or salvage:* collecting perishable produce from wholesalers and markets.
- *prepared food rescue:* collecting prepared foods from commercial kitchens.

food security: certain access to enough food for all people at all times to sustain a healthy and active life.

food substitutes: foods that are designed to replace other foods.

foodborne illness: illness transmitted to human beings through food and water, caused by either an infectious agent (foodborne infection) or a poisonous substance (food intoxication); commonly known as *food poisoning.*

foods: products derived from plants or animals that can be taken into the body to yield energy and nutrients for the maintenance of life and the growth and repair of tissues.

fortified: the addition to a food of nutrients that were either not originally present or present in insignificant amounts. Fortification can be used to correct or prevent a widespread nutrient deficiency or to balance the total nutrient profile of a food.

fraudulent: the promotion, for financial gain, of devices, treatments, services, plans, or products (including diets and supplements) that alter or claim to alter a human condition without proof of safety or effectiveness.

free: "nutritionally trivial" and unlikely to have a physiological consequence; synonyms include "without," "no," and "zero." A food that does not contain a nutrient naturally may make such a claim, but only as it applies to all similar foods (for example, "applesauce, a fat-free food").

free radicals: unstable and highly reactive atoms or molecules that have one or more unpaired electrons in the outer orbital. (See Appendix B for a review of basic chemistry concepts.)

French units: units of measure used to indicate the size of a feeding tube's outer diameter; 1 French unit equals 1/3 millimeter.

fructosamine test: a measurement of glycated serum proteins; used to analyze glycemic control over the preceding two weeks. Also known as the *glycated albumin test* or the *glycated serum protein test.*

fructose (FRUK-tose or FROOK-tose): a monosaccharide; sometimes known as fruit sugar

or **levulose.** Fructose is found abundantly in fruits, honey, and saps.

fuel: compounds that cells can use for energy. The major fuels include glucose, fatty acids, and amino acids; other fuels include ketone bodies, lactate, glycerol, and alcohol.

full liquid diet: a liquid diet that includes clear liquids, milk, yogurt, ice cream, and liquid nutritional supplements (such as Ensure).

functional foods: foods that contain physiologically active compounds that provide health benefits beyond their nutrient contributions; sometimes called *designer foods* or *nutraceuticals.*

futile: medical care that will not improve the medical circumstances of a patient.

G

galactose (ga-LAK-tose): a monosaccharide; part of the disaccharide lactose.

galactosemia (ga-LACK-toe-SEE-me-ah): an inherited disorder that affects galactose metabolism. Accumulated galactose causes damage to the liver, kidneys, and brain in untreated patients.

gallbladder: the organ that stores and concentrates bile. When it receives the signal that fat is present in the duodenum, the gallbladder contracts and squirts bile through the bile duct into the duodenum.

gallstones: stones that form in the gallbladder from crystalline deposits of cholesterol or bilirubin.

gangrene: death of tissue due to a deficient blood supply and/or infection.

gastrectomy (gah-STREK-ta-mee): the surgical removal of part of the stomach (partial gastrectomy) or the entire stomach (total gastrectomy).

gastric decompression: the removal of the stomach contents (swallowed saliva, stomach secretions, and gas) of patients who have motility disorders or obstructions that prevent stomach emptying.

gastric glands: exocrine glands in the stomach wall that secrete gastric juice into the stomach.

gastric juice: the digestive secretion of the gastric glands of the stomach.

gastric residual volume: the volume of formula remaining in the stomach from a previous feeding.

gastrin: a hormone secreted by cells in the stomach wall. Target organ: the glands of the stomach. Response: secretion of gastric acid.

gastritis: inflammation of stomach tissue.

gastroesophageal reflux: the backflow of stomach acid into the esophagus, causing damage to the cells of the esophagus and the sensation of heartburn. **Gastroesophageal reflux disease (GERD)** is characterized by symptoms of reflux occurring two or more times a week.

gastrointestinal (GI) tract: the digestive tract. The principal organs are the stomach and intestines.

gastroparesis (GAS-troe-pah-REE-sis): delayed stomach emptying.

gastrostomy (gah-STRAH-stoe-mee): an opening into the stomach through which a feeding tube can be passed. A nonsurgical technique for creating a gastrostomy under local anesthesia is called *percutaneous endoscopic gastrostomy (PEG).*

gatekeepers: with respect to nutrition, key people who control other people's access to foods and thereby exert profound impacts on their nutrition. Examples are the spouse who buys and cooks the food, the parent who feeds the children, and the caregiver in a day-care center.

gene expression: the process by which a cell converts the genetic code into RNA and protein.

gene pool: all the genetic information of a population at a given time.

gene therapy: treatment for inherited disorders, in which DNA sequences are introduced into the chromosomes of affected cells, prompting the cells to express the protein needed to correct the disease.

genes: sections of chromosomes that contain the instructions needed to make one or more proteins.

genetic counseling: support for families at risk of genetic disorders; involves diagnosis of disease, identification of inheritance patterns within the family, and review of reproductive options.

genetics: the study of genes and inheritance.

genome (GEE-nome): the full complement of genetic material (DNA) in the chromosomes of a cell. In human beings, the genome consists of 46 chromosomes. The study of genomes is called **genomics.**

genomics: the study of all the genes in an organism and their interactions with environmental factors.

gestation (jes-TAY-shun): the period from conception to birth. For human beings, the average length of a healthy gestation is 40 weeks. Pregnancy is often divided into three-month periods, called **trimesters.**

gestational diabetes: abnormal glucose tolerance during pregnancy.

ghrelin (GRELL-in): a protein produced by the stomach cells that enhances appetite and decreases energy expenditure.

gingiva (jin-JYE-va, or JIN-jeh-va): the gums.

gingivitis (jin-jeh-VYE-tus): inflammation of the gums; characterized by redness, swelling, and bleeding.

glands: cells or groups of cells that secrete materials for special uses in the body. Glands may be **exocrine** (EKS-oh-crin) **glands,** secreting their materials "out" (into the digestive tract or onto the surface of the skin), or **endocrine** (EN-doe-crin) **glands,** secreting their materials "in" (into the blood).

glomerular filtration rate (GFR): the rate at which filtrate is formed within the kidneys, normally approximately 125 mL/min.

glomerulus (gloh-MEHR-yoo-lus): a tuft of capillaries within the nephron that filters water and solutes from blood as urine production begins (plural: *glomeruli*).

glucagon (GLOO-ka-gon): a hormone that is secreted by special cells in the pancreas in response to low blood glucose concentration and elicits release of glucose from liver glycogen stores.

glucocorticoids: hormones from the adrenal cortex that affect the body's management of glucose.

gluconeogenesis (gloo-ko-nee-oh-JEN-ih-sis): the making of glucose from a noncarbohydrate source (described in more detail in Chapter 7).

glucose (GLOO-kose): a monosaccharide; sometimes known as blood sugar or **dextrose.**

glycated hemoglobin (HbA_{1c}): hemoglobin molecules to which glucose has been nonenzymatically attached; the level of HbA_{1c} in blood helps to evaluate long-term glycemic control. Also called *glycosylated hemoglobin.*

glycemic (gly-SEE-mic): pertaining to blood glucose.

glycemic index: a method of classifying foods according to their potential for raising blood glucose.

glycemic (gly-SEEM-ic) **response:** the extent to which a food raises the blood glucose concentration and elicits an insulin response.

glycerol (GLISS-er-ol): an alcohol composed of a three-carbon chain, which can serve as the backbone for a triglyceride.

glycogen (GLY-ko-jen): an animal polysaccharide composed of glucose; manufactured and stored in the liver and muscles as a storage form of glucose. Glycogen is not a significant food source of carbohydrate and is not counted as one of the complex carbohydrates in foods.

glycolysis (gly-COLL-ih-sis): the metabolic breakdown of glucose to pyruvate. Glycolysis does not require oxygen (anaerobic).

glycosuria (GLY-co-SOOR-ee-ah): an abnormal amount of glucose in urine.

goblet cells: cells of the GI tract (and lungs) that secrete mucus.

goiter (GOY-ter): an enlargement of the thyroid gland due to an iodine deficiency, malfunction of the gland, or overconsumption of a goitrogen. Goiter caused by iodine deficiency is **simple goiter.**

goitrogen (GOY-troh-jen): a substance that enlarges the thyroid gland and causes **toxic goiter.** Goitrogens occur naturally in such

foods as cabbage, kale, brussels sprouts, cauliflower, broccoli, and kohlrabi.

Golgi (GOAL-gee) **apparatus:** a set of membranes within the cell where secretory materials are packaged for export.

good source of: the product provides between 10 and 19% of the Daily Value for a given nutrient per serving.

gout (GOWT): a metabolic disorder characterized by elevated uric acid levels in the blood and urine and the deposition of uric acid in and around the joints, causing acute joint inflammation.

granulated sugar: crystalline sucrose; 99.9% pure.

growth hormone (GH): a hormone secreted by the pituitary that regulates the cell division and protein synthesis needed for normal growth (also called **somatotropin**). The release of GH is mediated by **GH-releasing hormone (GHRH)** and **GH-inhibiting hormone (GHIH).**

H

HACCP (Hazard Analysis and Critical Control Points): systems of food or formula preparation that identify food safety hazards and critical control points during foodservice procedures.

hard water: water with a high calcium and magnesium content.

HDL (high-density lipoprotein): the type of lipoprotein that transports cholesterol back to the liver from the cells; composed primarily of protein.

health care agent: a person given legal authority to make medical decisions for another in the event of incapacitation.

health claims: statements that characterize the relationship between a nutrient or other substance in a food and a disease or health-related condition.

healthy: a food that is low in fat, saturated fat, cholesterol, and sodium and that contains at least 10% of the Daily Values for vitamin A, vitamin C, iron, calcium, protein, or fiber.

Healthy People: a national public health initiative under the jurisdiction of the U.S. Department of Health and Human Services (DHHS) that identifies the most significant preventable threats to health and focuses efforts toward eliminating them.

heart failure: a condition with multiple causes characterized by the heart's inability to pump adequate blood to the body's cells, resulting in fluid accumulation in the tissues; also called *congestive heart failure.*

heartburn: a burning sensation in the chest area caused by backflow of stomach acid into the esophagus.

heavy metals: mineral ions such as mercury and lead, so called because they are of relatively high atomic weight. Many heavy metals are poisonous.

Heimlich (HIME-lick) **maneuver (abdominal thrust maneuver):** a technique for dislodging an object from the trachea of a choking person (see Figure H3-2); named for the physician who developed it.

Helicobacter pylori: a species of bacterium that colonizes gastric mucosa; a primary cause of gastritis and peptic ulcer disease.

helper T cells: lymphocytes that have a specific protein called CD4 on their surfaces and therefore are also known as *CD4+ T cells*; the cells most affected in HIV infection.

hematocrit (hee-MAT-oh-krit): measurement of the volume of the red blood cells packed by centrifuge in a given volume of blood.

hematuria (HE-mah-TOO-ree-ah): blood in the urine.

heme (HEEM): the iron-holding part of the hemoglobin and myoglobin proteins. About 40% of the iron in meat, fish, and poultry is bound into heme; the other 60% is **nonheme iron.**

hemochromatosis (HE-moh-KRO-ma-toe-sis): a genetically determined failure to prevent absorption of unneeded dietary iron that is characterized by iron overload and tissue damage.

hemodialysis (HE-moe-dye-AL-ih-sis): a treatment that removes fluids and wastes from the blood by passing the blood through a dialyzer.

hemofiltration: removal of fluid and solutes by pumping blood across a membrane; no osmotic gradients are created during the process.

hemoglobin (HE-moh-GLO-bin): the globular protein of the red blood cells that carries oxygen from the lungs to the cells throughout the body.

hemolytic (HE-moh-LIT-ick) **anemia:** the condition of having too few red blood cells as a result of erythrocyte hemolysis.

hemophilia (HE-moh-FEEL-ee-ah): inherited bleeding disorders characterized by deficiency or malfunction of plasma proteins needed for clotting blood.

hemorrhagic (hem-oh-RAJ-ik) **disease:** a disease characterized by excessive bleeding.

hemorrhagic strokes: strokes caused by bleeding within the brain, which destroys or compresses brain tissue.

hemorrhoids (HEM-oh-royds): painful swelling of the veins surrounding the rectum.

hemosiderin (heem-oh-SID-er-in): an iron storage protein primarily made in times of iron overload.

hemosiderosis (HE-moh-sid-er-OH-sis): a condition characterized by the deposition of hemosiderin in the liver and other tissues.

hepatic coma: loss of consciousness resulting from severe liver disease.

hepatic encephalopathy (en-sef-ah-LOP-ah-thie): a condition in advanced liver disease characterized by altered neurological functioning, including personality changes, reduced mental abilities, and disturbances in motor function.

hepatic portal vein: the vein that collects blood from the GI tract and conducts it to capillaries in the liver.

hepatic vein: the vein that collects blood from the liver capillaries and returns it to the heart.

hepatitis (hep-ah-TYE-tis): inflammation of the liver.

hepatomegaly (HEP-ah-toe-MEG-ah-lee): enlargement of the liver.

hepcidin: a hormone produced by the liver that regulates iron balance.

herpes simplex virus: a common virus that can cause blisterlike lesions on the lips and in the mouth.

hiatal hernia: a condition in which the upper portion of the stomach protrudes above the diaphragm; most cases are asymptomatic.

hiccups (HICK-ups): repeated cough-like sounds and jerks that are produced when an involuntary spasm of the diaphragm muscle sucks air down the windpipe; also spelled hiccoughs.

high fiber: 5 g or more fiber per serving. A high-fiber claim made on a food that contains more than 3 g fat per serving and per 100 g of food must also declare total fat.

high potency: 100% or more of the Daily Value for the nutrient in a single supplement and for at least two-thirds of the nutrients in a multinutrient supplement.

high-fructose corn syrup (HFCS): a syrup made from cornstarch that has been treated with an enzyme that converts some of the glucose to the sweeter fructose; made especially for use in processed foods and beverages, where it is the predominant sweetener. With a chemical structure similar to sucrose, HFCS has a fructose content of 42, 55, or 90%, with glucose making up the remainder.

high-quality proteins: dietary proteins containing all the essential amino acids in relatively the same amounts that human beings require. They may also contain nonessential amino acids.

high-risk pregnancy: a pregnancy characterized by indicators that make it likely the birth will be surrounded by problems such as premature delivery, difficult birth, retarded growth, birth defects, and early infant death.

high: 20% or more of the Daily Value for a given nutrient per serving; synonyms include "rich in" or "excellent source."

histamine (HISS-tah-mean or HISS-tah-men): a substance produced by cells of the immune system as part of a local immune reaction to an antigen; participates in causing inflammation.

histamine-2 receptor blockers: a class of drugs that suppress acid secretion by inhibit-

ing receptors on acid-producing cells; commonly called **H2 blockers**. Examples include cimetidine (Tagamet), ranitidine (Zantac), and famotidine (Pepcid).

HIV (human immunodeficiency virus): the virus that causes acquired immune deficiency syndrome (AIDS). HIV destroys immune cells and progressively impedes the body's ability to fight infections and certain cancers.

HIV-lipodystrophy (LIP-oh-DIS-tro-fee) **syndrome:** a group of abnormalities in fat and glucose metabolism that may result from drug treatments for HIV infection; changes include body fat redistribution, abnormal blood lipid levels, and insulin resistance. The accumulation of abdominal fat is sometimes called *protease paunch.*

hives: an allergic reaction characterized by raised, swollen patches of skin or mucous membranes that are associated with intense itching; also called *urticaria.*

homeopathic (HO-mee-oh-PATH-ic) **medicine:** a practice based on the theory that "like cures like"; that is, substances believed to cause certain symptoms are prescribed for curing the same symptoms, but are given in extremely diluted amounts.

homeostasis (HOME-ee-oh-STAY-sis): the maintenance of constant internal conditions (such as blood chemistry, temperature, and blood pressure) by the body's control systems. A homeostatic system is constantly reacting to external forces to maintain limits set by the body's needs.

honey: sugar (mostly sucrose) formed from nectar gathered by bees. An enzyme splits the sucrose into glucose and fructose. Composition and flavor vary, but honey always contains a mixture of sucrose, fructose, and glucose.

hormone: a chemical messenger. Hormones are secreted by a variety of endocrine glands in response to altered conditions in the body. Each hormone travels to one or more specific target tissues or organs, where it elicits a specific response to maintain homeostasis.

hormone-sensitive lipase: an enzyme inside adipose cells that responds to the body's need for fuel by hydrolyzing triglycerides so that their parts (glycerol and fatty acids) escape into the general circulation and thus become available to other cells for fuel. The signals to which this enzyme responds include epinephrine and glucagon, which oppose insulin (see Chapter 4).

human genome (GEE-nome): the full complement of genetic material in the chromosomes of a person's cells.

humoral immunity: immunity conferred by B cells, which produce and release antibodies into body fluids.

hunger: the painful sensation caused by a lack of food that initiates food-seeking behavior.

hydrochloric acid: an acid composed of hydrogen and chloride atoms (HCl) that is normally produced by the gastric glands.

hydrogenation (HIGH-dro-jen-AY-shun or high-DROJ-eh-NAY-shun): a chemical process by which hydrogens are added to monounsaturated or polyunsaturated fatty acids to reduce the number of double bonds, making the fats more saturated (solid) and more resistant to oxidation (protecting against rancidity). Hydrogenation produces *trans*-fatty acids.

hydrolysis (high-DROL-ih-sis): a chemical reaction in which a major reactant is split into two products, with the addition of a hydrogen atom (H) to one and a hydroxyl group (OH) to the other (from water, H_2O). (The noun is **hydrolysis;** the verb is **hydrolyze.**

hydrophilic (high-dro-FIL-ick): a term referring to water-loving, or water-soluble, substances.

hydrophobic (high-dro-FOE-bick): a term referring to water-fearing, or non-water-soluble, substances; also known as **lipophilic** (fat loving).

hydroxyapatite (high-drox-ee-APP-ah-tite): crystals made of calcium and phosphorus.

hyperactivity: inattentive and impulsive behavior that is more frequent and severe than is typical of others a similar age; professionally called **attention-deficit/hyperactivity disorder (ADHD).**

hypercalcemia (HIGH-per-kal-SEE-me-ah): elevated serum calcium levels.

hypercalciuria (HIGH-per-kal-see-YOO-ree-ah): elevated urinary calcium levels.

hypercapnia (high-per-CAP-nee-ah): excessive carbon dioxide in the blood.

hyperglycemia: elevated blood glucose concentrations. Normal fasting plasma glucose is less than 100 mg/dL. Fasting plasma glucose from 100 to 125 mg/dL suggests prediabetes; values of 126 mg/dL and above suggest diabetes.

hyperinsulinemia: abnormally high levels of insulin in the blood.

hyperkalemia (HIGH-per-ka-LEE-me-ah): elevated serum potassium levels.

hypermetabolism: a higher-than-normal metabolic rate.

hyperosmolar hyperglycemic state: extreme hyperglycemia associated with hyperosmolar blood, dehydration, and altered mental status; formerly called **hyperglycemic hyperosmolar nonketotic coma.**

hyperoxaluria (HIGH-per-ox-ah-LOO-ree-ah): elevated urinary oxalate levels.

hyperphosphatemia (HIGH-per-fos-fa-TEE-me-ah): elevated serum phosphate levels.

hypersensitivity: immune responses that are excessive or inappropriate. One type of hypersensitivity is *allergy*.

hypertonic formula: a formula with an osmolality greater than that of blood serum.

hypnotherapy: a technique that uses hypnosis and the power of suggestion to improve health behaviors, relieve pain, and promote healing.

hypoallergenic formulas: clinically tested infant formulas that support infant growth and development but do not provoke reactions in 90% of infants or children with confirmed cow's milk allergy.

hypochlorhydria (HIGH-poe-clor-HIGH-dree-ah): a reduction in gastric acid secretion.

hypoglycemia (HIGH-po-gly-SEE-me-ah): an abnormally low blood glucose concentration.

hypokalemia (HIGH-po-ka-LEE-me-ah): low serum potassium levels.

hypothalamus (high-po-THAL-ah-mus): a brain center that controls activities such as maintenance of water balance, regulation of body temperature, and control of appetite.

hypothesis (hi-POTH-eh-sis): an unproven statement that tentatively explains the relationships between two or more variables.

hypovolemia (HIGH-poe-voe-LEE-me-ah): low blood volume.

hypoxemia (high-pock-SEE-me-ah): a low level of oxygen in the blood.

hypoxia (high-POCK-see-ah): a low amount of oxygen in body tissues.

I

ileocecal (ill-ee-oh-SEEK-ul) valve: the sphincter separating the small and large intestines.

ileostomy (ill-ee-AH-stoe-me): a surgical procedure that creates a stoma using the ileum.

ileum (ILL-ee-um): the last segment of the small intestine.

imagery: the use of mental images of things or events to aid relaxation or promote self-healing.

imitation foods: foods that substitute for and resemble another food, but are nutritionally inferior to it with respect to vitamin, mineral, or protein content. If the substitute is not inferior to the food it resembles and if its name provides an accurate description of the product, it need not be labeled "imitation."

immune system: the body's defense system against foreign substances.

immunity: the body's ability to defend itself against diseases (see also Highlight 17).

immunoglobulins (IM-you-no-GLOB-you-linz): large globular proteins produced by B cells that function as antibodies.

implantation: the stage of development in which the zygote embeds itself in the wall of the uterus and begins to develop; occurs during the first two weeks after conception.

inborn error of metabolism: an inherited trait (one that is present at birth) that causes the absence, deficiency, or malfunction of a protein that has a critical metabolic role.

indigestion: incomplete or uncomfortable digestion, usually accompanied by pain, nausea, vomiting, heartburn, intestinal gas, or belching.

inflammation: a nonspecific response to injury or infection; a type of innate immune response.

inflammatory response: a group of nonspecific immune responses to infection or injury.

informed consent: a patient's or caregiver's agreement to undergo a treatment that has been adequately disclosed. Persons must be mentally competent in order to make the decision.

innate immunity: immunity that is present at birth, unchanging throughout life, and nonspecific for particular antigens; also called **natural immunity.**

inorganic: not containing carbon or pertaining to living things.

inositol (in-OSS-ih-tall): a nonessential nutrient that can be made in the body from glucose. Inositol is a part of cell membrane structures.

insoluble fibers: indigestible food components that do not dissolve in water. Examples include the tough, fibrous structures found in the strings of celery and the skins of corn kernels.

insulin (IN-suh-lin): a hormone secreted by special cells in the pancreas in response to (among other things) increased blood glucose concentration. The primary role of insulin is to control the transport of glucose from the bloodstream into the muscle and fat cells.

insulin resistance: the condition in which a normal amount of insulin produces a subnormal effect in muscle, adipose, and liver cells, resulting in an elevated fasting glucose; a metabolic consequence of obesity that precedes type 2 diabetes.

integrative medicine: medical care that combines mainstream medical treatments and referrals to practitioners of CAM therapies.

intermittent claudication (claw-dih-KAY-shun): severe pain and weakness in the legs (especially the calves) that is caused by inadequate blood supply to the muscles; it usually occurs with walking and subsides during rest.

intermittent feedings: delivery of about 250 to 400 milliliters of formula over 20 to 40 minutes.

Internet (the net): a worldwide network of millions of computers linked together to share information.

interstitial (IN-ter-STISH-al) fluid: fluid between the cells (intercellular), usually high in sodium and chloride. Interstitial fluid is a large component of extracellular fluid.

intestinal adaptation: after resection, the process of intestinal recovery that leads to improved absorptive capacity.

intra-abdominal fat: fat stored within the abdominal cavity in association with the internal abdominal organs, as opposed to the fat stored directly under the skin (subcutaneous fat).

intracellular fluid: fluid within the cells, usually high in potassium and phosphate. Intracellular fluid accounts for approximately two-thirds of the body's water.

intractable: not easily managed or controlled.

intractable vomiting: vomiting that is not easily managed or controlled.

intradialytic parenteral nutrition: the infusion of nutrients during hemodialysis, often providing amino acids, dextrose, lipids, and some trace minerals.

intravenous feedings: the provision of nutrients through a vein, bypassing the intestine; also called **parenteral nutrition.**

intrinsic factor: a glycoprotein (a protein with short polysaccharide chains attached) secreted by the stomach cells that binds with vitamin B_{12} in the small intestine to aid in the absorption of vitamin B_{12}.

invert sugar: a mixture of glucose and fructose formed by the hydrolysis of sucrose in a chemical process; sold only in liquid form and sweeter than sucrose. Invert sugar is used as a food additive to help preserve freshness and prevent shrinkage.

ions (EYE-uns): atoms or molecules that have gained or lost electrons and therefore have electrical charges. Examples include the positively charged sodium ion (Na^+) and the negatively charged chloride ion (Cl^-). For a closer look at ions, see Appendix B.

iron deficiency: the state of having depleted iron stores.

iron overload: toxicity from excess iron.

iron-deficiency anemia: severe depletion of iron stores that results in low hemoglobin and small, pale red blood cells. Anemias that impair hemoglobin synthesis are **microcytic** (small cell).

irritable bowel syndrome: an intestinal disorder of unknown cause that affects the functioning of the lower bowel; symptoms include abdominal pain, flatulence, diarrhea, and constipation.

ischemia (iss-KEE-mee-a): inadequate blood supply within tissues due to obstructed blood flow in the arteries.

ischemic strokes: strokes caused by the obstruction of blood flow to brain tissue.

isotonic formula: a formula with an osmolality similar to that of blood serum (about 300 milliosmoles per kilogram).

J

jaundice (JAWN-dis): yellow discoloration of the skin and eyes due to an accumulation of bilirubin, a breakdown product of hemoglobin that normally exits the body via bile secretions.

jejunostomy (JE-ju-NAH-stoe-mee): an opening in the jejunum through which a feeding tube can be passed. A nonsurgical technique for creating a jejunostomy is called *percutaneous endoscopic jejunostomy (PEJ)*. The tube can either be guided into the jejunum via a gastrostomy or passed directly into the jejunum *(direct PEJ)*.

jejunum (je-JOON-um): the first two-fifths of the small intestine beyond the duodenum.

K

Kaposi's (cap-OH-seez) **sarcoma:** a common cancer in HIV-infected persons that is characterized by lesions in the skin, lungs, and GI tract.

kcalorie (energy) control: management of food energy intake.

kcalorie counts: the determination of food energy (and often, protein) consumed by patients for one or more days.

kcalorie-free: fewer than 5 kcal per serving.

kefir (keh-FUR): a fermented milk created by adding *Lactobacillus acidophilus* and other bacteria that break down lactose to glucose and galactose, producing a sweet, lactose-free product.

keratin (KARE-uh-tin): a water-insoluble protein; the normal protein of hair and nails.

keratinization: accumulation of keratin in a tissue; a sign of vitamin A deficiency.

keratomalacia (KARE-ah-toe-ma-LAY-shuh): softening of the cornea that leads to irreversible blindness; seen in severe vitamin A deficiency.

keto (KEY-toe) **acid:** an organic acid that contains a carbonyl group (C=O).

ketoacidosis (KEY-toe-ass-ih-DOE-sis): an acidosis (lowering of blood pH) that results from the excessive production of ketone bodies.

ketone (KEE-tone) **bodies:** the product of the incomplete breakdown of fat when glucose is not available in the cells.

ketonuria (KEY-toe-NOOR-ee-ah): the presence of ketone bodies in the urine.

ketosis (kee-TOE-sis): an undesirably high concentration of ketone bodies in the blood and urine.

kidney stones: crystalline masses that form in the urinary tract; also called *renal calculi* and *nephrolithiasis.*

kwashiorkor (kwash-ee-OR-core, kwash-ee-or-CORE): a form of PEM that results either from inadequate protein intake or, more commonly, from infections.

L

lactadherin (lack-tad-HAIR-in): a protein in breast milk that attacks diarrhea-causing viruses.

lactase: an enzyme that hydrolyzes lactose.

lactase deficiency: a lack of the enzyme required to digest the disaccharide lactose

into its component monosaccharides (glucose and galactose).

lactate: a 3-carbon compound produced from pyruvate during anaerobic metabolism.

lactation: production and secretion of breast milk for the purpose of nourishing an infant.

lacto-ovo-vegetarians: people who include milk, milk products, and eggs, but exclude meat, poultry, fish, and seafood from their diets.

lactoferrin (lack-toh-FERR-in): a protein in breast milk that binds iron and keeps it from supporting the growth of the infant's intestinal bacteria.

lactose (LAK-tose): a disaccharide composed of glucose and galactose; commonly known as milk sugar.

lactose intolerance: a condition that results from inability to digest the milk sugar lactose; characterized by bloating, gas, abdominal discomfort, and diarrhea. Lactose intolerance differs from milk allergy, which is caused by an immune reaction to the protein in milk.

lactovegetarians: people who include milk and milk products, but exclude meat, poultry, fish, seafood, and eggs from their diets.

laparoscopic: pertaining to procedures that use a laparoscope for internal examination or surgery. A laparoscope is a narrow surgical telescope that is inserted into the body through a small incision. A video camera is usually attached so that the procedure can be viewed on a television monitor.

large intestine or **colon** (COAL-un): the lower portion of intestine that completes the digestive process. Its segments are the ascending colon, the transverse colon, the descending colon, and the sigmoid colon.

larynx: the upper part of the air passageway that contains the vocal cords; also called the voice box (see Figure H3-1).

laxatives: substances that loosen the bowels and thereby prevent or treat constipation.

LDL (low-density lipoprotein): the type of lipoprotein derived from very-low-density lipoproteins (VLDL) as VLDL triglycerides are removed and broken down; composed primarily of cholesterol.

lean: less than 10 g of fat, 4.5 g of saturated fat and *trans* fat combined, and 95 mg of cholesterol per serving and per 100 g of meat, poultry, and seafood.

lean body mass: the body minus its fat content.

lecithin (LESS-uh-thin): one of the phospholipids. Both nature and the food industry use lecithin as an emulsifier to combine water-soluble and fat-soluble ingredients that do not ordinarily mix, such as water and oil.

legumes (lay-GYOOMS, or LEG-yooms): plants of the bean and pea family, with seeds that are rich in protein compared with other plant-derived foods.

leptin: a protein produced by fat cells under direction of the *ob* gene that decreases appetite and increases energy expenditure; sometimes called the ***ob* protein.**

less: at least 25% less of a given nutrient or kcalories than the comparison food (see individual nutrients); synonyms include "fewer" and "reduced."

less cholesterol: 25% or less cholesterol than the comparison food (reflecting a reduction of at least 20 mg per serving), and 2 g or less saturated fat and *trans* fat combined per serving.

less fat: 25% or less fat than the comparison food.

less saturated fat: 25% or less saturated fat and *trans* fat combined than the comparison food.

let-down reflex: the reflex that forces milk to the front of the breast when the infant begins to nurse.

leukocytes: blood cells that function in immunity; also called *white blood cells.*

levulose: an older name for fructose.

license to practice: permission under state or federal law, granted on meeting specified criteria, to use a certain title (such as dietitian) and offer certain services. **Licensed dietitians** may use the initials **LD** after their names.

life expectancy: the average number of years lived by people in a given society.

life span: the maximum number of years of life attainable by a member of a species.

light or **lite:** one-third fewer kcalories than the comparison food; 50% or less of the fat or sodium than the comparison food; any use of the term other than as defined must specify what it is referring to (for example, "light in color" or "light in texture").

lignans: phytochemicals present in flaxseed, but not in flax oil, that are converted to phytosterols by intestinal bacteria and are under study as possible anticancer agents.

limiting amino acid: the essential amino acid found in the shortest supply relative to the amounts needed for protein synthesis in the body. Four amino acids are most likely to be limiting:
- Lysine
- Methionine
- Threonine
- Tryptophan

linoleic (lin-oh-LAY-ick) **acid:** an essential fatty acid with 18 carbons and two double bonds.

linolenic (lin-oh-LEN-ick) **acid:** an essential fatty acid with 18 carbons and three double bonds.

lipids: a family of compounds that includes triglycerides, phospholipids, and sterols. Lipids are characterized by their insolubility in water. (Lipids also include the fat-soluble vitamins, described in Chapter 11.)

lipomas (lih-POE-muz): benign tumors composed of fatty tissue.

lipoprotein lipase (LPL): an enzyme that hydrolyzes triglycerides passing by in the bloodstream and directs their parts into the cells, where they can be metabolized for energy or reassembled for storage.

lipoproteins (LIP-oh-PRO-teenz): clusters of lipids associated with proteins that serve as transport vehicles for lipids in the lymph and blood.

listeriosis: an infection caused by eating food contaminated with the bacterium *Listeria monocytogenes,* which can be killed by pasteurization and cooking but can survive at refrigerated temperatures; certain ready-to-eat foods, such as hot dogs and deli meats, may become contaminated after cooking or processing, but before packaging.

liver: the organ that manufactures bile. (The liver's many other functions are described in Chapter 7.)

living will: a written statement that specifies the medical procedures desired or not desired in the event that a person is unable to communicate or is incapacitated; also called a *medical directive.*

longevity: long duration of life.

low: an amount that would allow frequent consumption of a food without exceeding the Daily Value for the nutrient. A food that is naturally low in a nutrient may make such a claim, but only as it applies to all similar foods (for example, "fresh cauliflower, a low-sodium food"); synonyms include "little," "few," and "low source of."

low birthweight (LBW): a birthweight of $5\frac{1}{2}$ lb (2500 g) or less; indicates probable poor health in the newborn and poor nutrition status in the mother during pregnancy, before pregnancy, or both. Normal birthweight for a full-term baby is $6\frac{1}{2}$ to $8\frac{3}{4}$ lb (about 3000 to 4000 g).

low cholesterol: 20 mg or less cholesterol per serving and 2 g or less saturated fat and *trans* fat combined per serving.

low fat: 3 g or less fat per serving.

low kcalorie: 40 kcal or less per serving.

low saturated fat: 1 g or less saturated fat and less than 0.5 g of *trans* fat per serving.

low sodium: 140 mg or less per serving.

low-residue diet: a diet low in fiber and other food constituents that contribute to colonic residue.

low-risk pregnancy: a pregnancy characterized by indicators that make a normal outcome likely.

lumen (LOO-men): the space within a vessel, such as the intestine.

lutein (LOO-teen): a plant pigment of yellow hue; a phytochemical believed to play roles in eye functioning and health.

luteinizing (LOO-tee-in-EYE-zing) **hormone (LH):** a hormone that stimulates ovulation and the development of the corpus luteum (the small tissue that develops from a ruptured ovarian follicle and secretes hormones); so called because the follicle turns yellow as it matures. In men, LH stimulates testosterone secretion. The release of LH is mediated by **luteinizing hormone–releasing hormone (LH–RH).**

lycopene (LYE-koh-peen): a pigment responsible for the red color of tomatoes and other red-hued vegetables; a phytochemical that may act as an antioxidant in the body.

lymph (LIMF): a clear yellowish fluid that is similar to blood except that it contains no red blood cells or platelets. Lymph from the GI tract transports fat and fat-soluble vitamins to the bloodstream via lymphatic vessels.

lymphatic (lim-FAT-ic) **system:** a loosely organized system of vessels and ducts that convey fluids toward the heart. The GI part of the lymphatic system carries the products of fat digestion into the bloodstream.

lymphatic vessels: vessels through which lymph travels.

lymphocytes (LIM-foe-sites): white blood cells that recognize specific antigens and therefore function in adaptive immunity; include *T cells* and *B cells.*

lymphoid tissues: tissues that have roles in immunity.

lysosomes (LYE-so-zomes): cellular organelles; membrane-enclosed sacs of degradative enzymes.

lysozyme (LYE-so-zyme): an enzyme with antibacterial properties; found in immune cells and body secretions such as tears, saliva, and sweat.

M

macrobiotic diets: extremely restrictive diets limited to a few grains and vegetables; based on metaphysical beliefs and not on nutrition. A macrobiotic diet might consist of brown rice, miso soup, and sea vegetables, for example.

macrocytic anemia: anemia characterized by large red blood cells, as occurs in folate and vitamin B_{12} deficiency; also called **megaloblastic anemia.**

macrophages (MAK-roe-fay-jez): monocytes that have left circulation and settled in a tissue, where they serve as scavengers and activate the immune response.

macrosomia (MAK-roh-SOH-mee-ah): the condition of having an abnormally large body; in infants, refers to birth weights of 4000 g (8 lb 13 oz) and above.

macrovascular complications: disorders that affect the large blood vessels, including the coronary arteries and arteries of the limbs.

macular (MACK-you-lar) **degeneration:** deterioration of the macular area of the eye that can lead to loss of central vision and eventual blindness. The **macula** is a small, oval, yellowish region in the center of the retina that provides the sharp, straight-ahead vision so critical to reading and driving.

magnesium: a cation within the body's cells, active in many enzyme systems.

major minerals: essential mineral nutrients found in the human body in amounts larger than 5 g; sometimes called **macrominerals.**

maleficence (mah-LEF-eh-sense): the act of doing evil or harm.

malignant (ma-LIG-nent): describes a cancerous cell or tumor, which can injure healthy tissue and spread cancer to other regions of the body.

malnutrition: any condition caused by excess or deficient food energy or nutrient intake or by an imbalance of nutrients.

maltase: an enzyme that hydrolyzes maltose

maltose (MAWL-tose): a disaccharide composed of two glucose units; sometimes known as *malt sugar.*

mammary glands: glands of the female breast that secrete milk.

maple sugar: a sugar (mostly sucrose) purified from the concentrated sap of the sugar maple tree.

marasmus (ma-RAZ-mus): a form of PEM that results from a severe deprivation, or impaired absorption, of energy, protein, vitamins, and minerals.

massage therapy: manual manipulation of muscles to reduce tension, increase blood circulation, improve joint mobility, and promote healing of injuries.

mast cells: cells within connective tissue that produce and release histamine.

matrix (MAY-tricks): the basic substance that gives form to a developing structure; in the body, the formative cells from which teeth and bones grow.

matter: anything that takes up space and has mass.

Meals on Wheels: a nutrition program that delivers food for the elderly to their homes.

meat replacements: products formulated to look and taste like meat, fish, or poultry; usually made of textured vegetable protein.

mechanical ventilation: life-sustaining treatment in which a mechanical ventilator is used to substitute for a patient's failing lungs.

medical nutrition therapy: nutrition care provided by a registered dietitian; includes assessing nutrition status, diagnosing nutrition problems, and providing nutrition care.

meditation: a self-directed technique of calming the mind and relaxing the body.

medium-chain triglycerides (MCT): triglycerides that contain fatty acids that are 8 to 10 carbons in length. MCT do not require digestion and can be absorbed in the absence of lipase or bile.

MEOS or **microsomal** (my-krow-SO-mal) **ethanol-oxidizing system:** a system of enzymes in the liver that oxidize not only alcohol but also several classes of drugs.

metabolic stress: a disruption in the body's chemical environment due to the effects of disease or injury. Metabolic stress is characterized by changes in metabolic rate, heart rate, blood pressure, hormonal status, and nutrient metabolism.

metabolic syndrome: a cluster of interrelated clinical symptoms, including obesity, insulin resistance, high blood pressure, and abnormal blood lipids, which together increase cardiovascular disease risk twofold to threefold; also known as *syndrome X* or *insulin resistance syndrome.*

metabolism: the sum total of all the chemical reactions that go on in living cells. Energy metabolism includes all the reactions by which the body obtains and expends the energy from food.

metabolites: products of metabolism; compounds produced by a biochemical pathway.

metalloenzymes (meh-TAL-oh-EN-zimes): enzymes that contain one or more minerals as part of their structures.

metallothionein (meh-TAL-oh-THIGH-oh-neen): a sulfur-rich protein that avidly binds with and transports metals such as zinc.

metastasize (meh-TAS-tah-size): the spread of cancer cells from one part of the body to another.

MFP factor: a peptide released during the digestion of **m**eat, **f**ish, and **p**oultry that enhances nonheme iron absorption.

micelles (MY-cells): tiny spherical complexes of emulsified fat that arise during digestion; most contain bile salts and the products of lipid digestion, including fatty acids, monoglycerides, and cholesterol.

microalbuminuria: the presence of albumin (a blood protein) in the urine, a sign of diabetic nephropathy.

microarray technology: research tools that analyze the expression of thousands of genes simultaneously and search for particular gene changes associated with a disease. DNA microarrays are also called *DNA chips.*

microcytic anemia: anemia characterized by small, hypochromic (pale) red blood cells, as occurs in iron deficiency.

microvascular complications: disorders that affect the small blood vessels and capillaries, including those in the retinas and kidneys.

microvilli (MY-cro-VILL-ee, MY-cro-VILL-eye): tiny, hairlike projections on each cell of every villus that can trap nutrient particles and transport them into the cells; singular **microvillus.**

milk anemia: iron-deficiency anemia that develops when an excessive milk intake displaces iron-rich foods from the diet.

milliequivalents (mEq): the concentration of electrolytes in a volume of solution. Milliequivalents are a useful measure when considering ions because the number of charges reveals characteristics about the solution that are not evident when the concentration is expressed in terms of weight.

mineral oil: a purified liquid derived from petroleum and used to treat constipation.

mineral water: water from a spring or well that typically contains 250 to 500 parts per million (ppm) of minerals. Minerals give water a distinctive flavor. Many mineral waters are high in sodium.

mineralization: the process in which calcium, phosphorus, and other minerals crystallize on the collagen matrix of a growing bone, hardening the bone.

minerals: inorganic elements. Some minerals are essential nutrients required in small amounts by the body for health.

misinformation: false or misleading information.

mitochondria (my-toh-KON-dree-uh); singular **mitochondrion:** the cellular organelles responsible for producing ATP aerobically; made of membranes (lipid and protein) with enzymes mounted on them.

moderation: in relation to alcohol consumption, not more than two drinks a day for the average-size man and not more than one drink a day for the average-size woman.

moderation (dietary): providing enough but not too much of a substance.

modified diet: a diet that is altered by changing food consistency or nutrient content or by including or eliminating specific foods; also called a *therapeutic diet.*

modular formulas: enteral formulas prepared in the hospital from *modules* that contain single macronutrients; used for people with unique nutrient needs.

molasses: the thick brown syrup produced during sugar refining. Molasses retains residual sugar and other by-products and a few minerals; blackstrap molasses contains significant amounts of calcium and iron.

molecule: two or more atoms of the same or different elements joined by chemical bonds. Examples are molecules of the element oxygen, composed of two oxygen atoms (O_2), and molecules of the compound water, composed of two hydrogen atoms and one oxygen atom (H_2O).

molybdenum (mo-LIB-duh-num): a trace element.

monocytes (MON-oh-sites): cells released from the bone marrow that move into tissues and mature into macrophages.

monoglycerides: molecules of glycerol with one fatty acid attached. A molecule of glycerol with two fatty acids attached is a **diglyceride.**

monosaccharides (mon-oh-SACK-uh-rides): carbohydrates of the general formula $C_nH_{2n}O_n$ that typically form a single ring. See Appendix C for the chemical structures of the monosaccharides.

monounsaturated fatty acid (MUFA): a fatty acid that lacks two hydrogen atoms and has one double bond between carbons—for example, oleic acid. A **monounsaturated fat** is composed of triglycerides in which most of the fatty acids are monounsaturated.

more: at least 10% more of the Daily Value for a given nutrient than the comparison food; synonyms include "added" and "extra."

mouth: the oral cavity containing the tongue and teeth.

mucous (MYOO-kus) **membranes:** the membranes, composed of mucus-secreting cells, that line the surfaces of body tissues.

mucus (MYOO-kus): a slippery substance secreted by cells of the GI lining (and other body linings) that protects the cells from exposure to digestive juices (and other destructive agents). The lining of the GI tract with its coat of mucus is a **mucous membrane.** (The noun is **mucus**; the adjective is **mucous**.)

multiple organ dysfunction syndrome: the dysfunction of two or more organ systems that develops during intensive care; often results in death.

muscle dysmorphia (dis-MORE-fee-ah): a psychiatric disorder characterized by a preoccupation with building body mass.

muscular dystrophy (DIS-tro-fee): a hereditary disease in which the muscles gradually weaken. Its most debilitating effects arise in the lungs.

mutation: an inheritable alteration in the DNA sequence of a gene.

myocardial (MY-oh-CAR-dee-al) **infarction** (in-FARK-shun), or **MI:** death of heart muscle caused by a sudden reduction in coronary blood flow; also called a *heart attack* or *cardiac arrest.*

myoglobin: the oxygen-holding protein of the muscle cells.

N

NAD (nicotinamide adenine dinucleotide): the main coenzyme form of the vitamin niacin. Its reduced form is NADH.

narcotic (nar-KOT-ic): a drug that dulls the senses, induces sleep, and becomes addictive with prolonged use.

nasoduodenal (ND): tube is placed into the duodenum via the nose.

nasoenteric: tube is placed into the GI tract via the nose. (*Nasoenteric feedings* usually refer to *nasoduodenal* and *nasojejunal* feedings.)

nasogastric (NG): tube is placed into the stomach via the nose.

nasojejunal (NJ): tube is placed into the jejunum via the nose.

National Center for Complementary and Alternative Medicine (NCCAM): a federal agency that researches and provides information about complementary and alternative therapies.

natural killer cells: lymphocytes that confer nonspecific immunity by destroying a wide array of viruses and tumor cells.

natural water: water obtained from a spring or well that is certified to be safe and sanitary. The mineral content may not be changed, but the water may be treated in other ways such as with ozone or by filtration.

naturopathic (NAY-chur-oh-PATH-ic) **medicine:** an approach to medical care using practices alleged to enhance the body's natural healing abilities. Treatments may include a variety of alternative therapies including dietary supplements, herbal remedies, exercise, and homeopathy.

neotame (NEE-oh-tame): an artificial sweetener composed of two amino acids (phenylalanine and aspartic acid); approved for use in the United States.

nephron (NEF-ron): the functional unit of the kidneys, consisting of a glomerulus and tubules.

nephrotic (neh-FROT-ik) **syndrome:** a syndrome associated with kidney disorders that cause urinary protein losses exceeding 3.0 to 3.5 g/day; symptoms include low serum albumin, elevated blood lipids, and edema.

nephrotoxic: toxic to the kidneys.

net protein utilization (NPU): a measure of protein quality assessed by measuring the amount of protein nitrogen that is retained from a given amount of protein nitrogen eaten.

neural tube: the embryonic tissue that forms the brain and spinal cord.

neural tube defects: malformations of the brain, spinal cord, or both during embryonic development that often result in lifelong disability or death.

neurofibrillary tangles: snarls of the thread-like strands that extend from the nerve cells, commonly found in the brains of people with Alzheimer's dementia.

neurons: nerve cells; the structural and functional units of the nervous system. Neurons initiate and conduct nerve impulse transmissions.

neuropeptide Y: a chemical produced in the brain that stimulates appetite, diminishes energy expenditure, and increases fat storage.

neurotransmitters: chemicals that are released at the end of a nerve cell when a nerve impulse arrives there. They diffuse

across the gap to the next cell and alter the membrane of that second cell to either inhibit or excite it.

neutrophils (NEW-tro-fills): the most common type of white blood cell. Neutrophils destroy antigens by phagocytosis.

niacin (NIGH-a-sin): a B vitamin. The coenzyme forms are **NAD (nicotinamide adenine dinucleotide)** and **NADP (the phosphate form of NAD).** Niacin can be eaten preformed or made in the body from its precursor, tryptophan, one of the amino acids.

niacin equivalents (NE): the amount of niacin present in food, including the niacin that can theoretically be made from its precursor, tryptophan, present in the food.

niacin flush: a temporary burning, tingling, and itching sensation that occurs when a person takes a large dose of nicotinic acid; often accompanied by a headache and reddened face, arms, and chest.

night blindness: slow recovery of vision after flashes of bright light at night or an inability to see in dim light; an early symptom of vitamin A deficiency.

nitric oxide: a compound produced by blood vessel cells that helps to regulate blood vessel activity, including dilation and constriction.

nitrogen balance: the amount of nitrogen consumed (N in) as compared with the amount of nitrogen excreted (N out) in a given period of time.

nonessential amino acids: amino acids that the body can synthesize (see Table 6-1).

nonnutrients: compounds in foods that do not fit into the six classes of nutrients.

nonnutritive sweeteners: sweeteners that yield no energy (or insignificant energy in the case of aspartame).

nonpathogenic: not capable of causing disease.

nonprotein kcalorie-to-nitrogen ratio: a ratio between the nonprotein kcalories and nitrogen content of the diet; used to assess whether the nitrogen intake is sufficient for maintaining muscle tissue.

nonselective menus: menus that do not allow choices and list only preselected food items.

nucleotide bases: the nitrogen-containing building blocks of DNA and RNA—cytosine (C), thymine (T), uracil (U), guanine (G), and adenine (A). In DNA, the base pairs are A–T and C–G and in RNA, the base pairs are A–U and C–G.

nucleotides: the subunits of DNA and RNA molecules, composed of a phosphate group, a 5-carbon sugar (deoxyribose for DNA and ribose for RNA), and a nitrogen-containing base.

nucleus: a major membrane-enclosed body within every cell, which contains the cell's genetic material, DNA, embedded in chromosomes.

nursing bottle tooth decay: extensive tooth decay due to prolonged tooth contact with formula, milk, fruit juice, or other carbohydrate-rich liquid offered to an infant in a bottle.

nursing diagnoses: clinical judgments about actual or potential health problems that provide the basis for selecting appropriate nursing interventions.

nutrient claims: statements that characterize the quantity of a nutrient in a food.

nutrient density: a measure of the nutrients a food provides relative to the energy it provides. The more nutrients and the fewer kcalories, the higher the nutrient density.

nutrients: chemical substances obtained from food and used in the body to provide energy, structural materials, and regulating agents to support growth, maintenance, and repair of the body's tissues. Nutrients may also reduce the risks of some diseases.

nutrition: the science of foods and the nutrients and other substances they contain, and of their actions within the body (including ingestion, digestion, absorption, transport, metabolism, and excretion). A broader definition includes the social, economic, cultural, and psychological implications of food and eating.

nutrition assessment: a comprehensive analysis of a person's nutrition status that uses health, socioeconomic, drug, and diet histories; anthropometric measurements; physical examinations; and laboratory tests.

nutrition care plans: strategies for meeting an individual's nutritional needs.

nutrition care process: a problem-solving method that dietetics professionals use to evaluate and treat nutrition-related problems.

nutrition prescription: specific dietary recommendations related to food, nutrient, or energy intake or feeding method.

nutrition screening: a brief assessment of health-related variables to identify patients who are malnourished or at risk for malnutrition.

nutrition support: the delivery of formulated nutrients via a feeding tube or intravenous infusion.

nutrition support teams: health care professionals responsible for the provision of nutrients by tube feeding or intravenous infusion.

nutritional genomics: the science of how food (and its components) interacts with the genome. The study of how nutrients affect the activities of genes is called *nutrigenomics.* The study of how genes affect the activities of nutrients is called *nutrigenetics.*

nutritionist: a person who specializes in the study of nutrition. Note that this definition does not specify qualifications and may apply not only to registered dietitians but also to self-described experts whose training is questionable. Most states have licensing laws that define the scope of practice for those calling themselves nutritionists.

nutritive sweeteners: sweeteners that yield energy, including both sugars and sugar replacers.

O

obese: overweight with adverse health effects; BMI 30 or higher.

oils: lipids that are liquid at room temperature (77°F or 25°C).

olestra: a synthetic fat made from sucrose and fatty acids that provides 0 kcalories per gram; also known as **sucrose polyester.**

oliguria (OL-lih-GOO-ree-ah): an abnormally low amount of urine, often less than 400 mL/day.

omega: the last letter of the Greek alphabet (Ω), used by chemists to refer to the position of the first double bond from the methyl (CH_3) end of a fatty acid.

omega-3 fatty acid: a polyunsaturated fatty acid in which the first double bond is three carbons away from the methyl (CH_3) end of the carbon chain.

omega-6 fatty acid: a polyunsaturated fatty acid in which the first double bond is six carbons from the methyl (CH_3) end of the carbon chain.

omnivores: people who have no formal restriction on the eating of any foods.
oncotic pressure: the pressure exerted by fluid on one side of a membrane as a result of osmosis.

open feeding system: a delivery system that requires the formula to be transferred from its original packaging to a feeding container before being administered through the feeding tube.

opportunistic infections: infections from microorganisms that normally do not cause disease in healthy people, but are damaging to persons with compromised immune function.

opsin (OP-sin): the protein portion of the visual pigment molecule.

oral allergy syndrome: an allergic response in which symptoms of hives, swelling, or itching occur only in the mouth and throat; usually a short-lived response that resolves quickly.

oral glucose tolerance test: a test that evaluates a person's ability to tolerate an oral glucose load.

organelles: subcellular structures such as ribosomes, mitochondria, and lysosomes.

organic: in chemistry, a substance or molecule containing carbon-carbon bonds or carbon-hydrogen bonds. This definition excludes coal, diamonds, and a few carbon-containing compounds that contain only a single carbon and no hydrogen, such as carbon dioxide (CO_2), calcium carbonate ($CaCO_3$).

magnesium carbonate ($MgCO_3$), and sodium cyanide (NaCN).

organic: on food labels, that at least 95% of the product's ingredients have been grown and processsed according to USDA regulations defining the use of fertilizers, herbicides, insecticides, fungicides, preservatives, and other chemical ingredients.

orlistat (OR-leh-stat): a drug used in the treatment of obesity that inhibits the absorption of fat in the GI tract, thus limiting kcaloric intake.

orogastric: tube is placed into the stomach via the mouth. This method is often used to feed infants because a nasogastric tube can hinder the infant's breathing.

oropharyngeal (OR-oh-fah-ren-JEE-al): involving the mouth and pharynx.

oropharyngeal dysphagia: an inability to transfer food from the mouth and pharynx to the esophagus; usually caused by a neurological or muscular disorder.

osmolality (OZ-moe-LAL-ih-tee): the concentration of osmotically active solutes in a solution, expressed as milliosmoles (mOsm) per kilogram of solvent.

osmolarity: the concentration of osmotically active particles in a solution, expressed as milliosmoles per liter (mOsm/L). *Osmolality* is an alternative expression of a solution's osmotic properties that is used in clinical practice and is expressed as milliosmoles per kilogram (mOsm/kg).

osmosis: the movement of water across a membrane toward the side where the solutes are more concentrated.

osmotic pressure: the amount of pressure needed to prevent the movement of water across a membrane.

osteoarthritis: a painful, degenerative disease of the joints that occurs when the cartilage in a joint deteriorates; joint structure is damaged, with loss of function; also called **degenerative arthritis.**

osteomalacia (OS-tee-oh-ma-LAY-shuh): a bone disease characterized by softening of the bones. Symptoms include bending of the spine and bowing of the legs. The disease occurs most often in adult women.

osteopathic (OS-tee-oh-PATH-ic) **manipulation:** a CAM technique performed by a doctor of osteopathy (D.O., or osteopath) that includes deep tissue massage and manipulation of the joints, spine, and soft tissues. A D.O. is a fully trained and licensed medical physician, although osteopathic manipulation has not been proved to be an effective treatment.

osteoporosis (OS-tee-oh-pore-OH-sis): a disease in which the bones become porous and fragile due to a loss of minerals; also called **adult bone loss.**

overnutrition: excess energy or nutrients.

overt (oh-VERT): out in the open and easy to observe.

overweight: body weight above some standard of acceptable weight that is usually defined in relation to height (such as BMI); BMI 25 to 29.9.

ovum (OH-vum): the female reproductive cell, capable of developing into a new organism upon fertilization; commonly referred to as an egg.

oxaloacetate (OKS-ah-low-AS-eh-tate): a carbohydrate intermediate of the TCA cycle.

oxidants (OKS-ih-dants): compounds (such as oxygen itself) that oxidize other compounds. Compounds that prevent oxidation are called *antioxidants,* whereas those that promote it are called *prooxidants*.

oxidation (OKS-ee-day-shun): the process of a substance combining with oxygen; oxidation reactions involve the loss of electrons.

oxidative stress: a condition in which the production of oxidants and free radicals exceeds the body's ability to handle them and prevent damage.

oxytocin (OCK-see-TOH-sin): a hormone that stimulates the mammary glands to eject milk during lactation and the uterus to contract during childbirth.

oyster shell: a product made from the powdered shells of oysters that is sold as a calcium supplement, but it is not well absorbed by the digestive system.

P

pancreas: a gland that secretes digestive enzymes and juices into the duodenum. (The pancreas also secretes hormones into the blood that help to maintain glucose homeostasis.)

pancreatic (pank-ree-AT-ic) **juice:** the exocrine secretion of the pancreas, containing enzymes for the digestion of carbohydrate, fat, and protein as well as bicarbonate, a neutralizing agent. The juice flows from the pancreas into the small intestine through the pancreatic duct. (The pancreas also has an endocrine function, the secretion of insulin and other hormones.)

pantothenic (PAN-toe-THEN-ick) **acid:** a B vitamin. The principal active form is part of coenzyme A, called "CoA" throughout Chapter 7.

paracentesis (pah-rah-sen-TEE-sis): a surgical puncture of a body cavity with an aspirator to draw out excess fluid.

parathyroid hormone: a hormone from the parathyroid glands that regulates blood calcium by raising it when levels fall too low; also known as **parathormone** (PAIR-ah-THOR-moan).

parenteral (par-EN-ter-al) **nutrition:** the intravenous provision of nutrients that bypasses the GI tract.

pasteurization: heat processing of food that inactivates some, but not all, microorganisms in the food; not a sterilization process. Bacteria that cause spoilage are still present.

pathogen (PATH-oh-jen): a microorganism capable of producing disease.

pathogenic: capable of causing disease.

patient autonomy: a principle of self-determination, such that patients (or surrogate decision makers) are free to choose the medical interventions that are acceptable to them, even if they choose to refuse interventions that may extend their lives.

PDCAAS (protein digestibility–corrected amino acid score): a measure of protein quality assessed by comparing the amino acid score of a food protein with the amino acid requirements of preschool-age children and then correcting for the true digestibility of the protein; recommended by the FAO/WHO and used to establish protein quality of foods for Daily Value percentages on food labels.

peak bone mass: the highest attainable bone density for an individual, developed during the first three decades of life.

peer review: a process in which a panel of scientists rigorously evaluates a research study to assure that the scientific method was followed.

pellagra (pell-AY-gra): the niacin-deficiency disease.

pepsin: a gastric enzyme that hydrolyzes protein. Pepsin is secreted in an inactive form, **pepsinogen,** which is activated by hydrochloric acid in the stomach.

peptic ulcer: an erosion in the gastrointestinal mucosa resulting from the destructive effects of gastric acid and pepsin; may develop in the esophagus, stomach, or duodenum.

peptidase: a digestive enzyme that hydrolyzes peptide bonds. *Tripeptidases* cleave tripeptides; *dipeptidases* cleave dipeptides. *Endopeptidases* cleave peptide bonds within the chain to create smaller fragments, whereas *exopeptidases* cleave bonds at the ends to release free amino acids.

peptide bond: a bond that connects the acid end of one amino acid with the amino end of another, forming a link in a protein chain.

percent fat-free: may be used only if the product meets the definition of *low fat* or *fat-free* and must reflect the amount of fat in 100 g (for example, a food that contains 2.5 g of fat per 50 g can claim to be "95 percent fat free").

periodontal disease: a disease that affects the connective tissue structures that support the teeth.

periodontitis: inflammation or degeneration of the tissues that support the teeth.

periodontium: the tissues that support the teeth, including the gums, cementum (bone-like material covering the dentin layer of the tooth), periodontal ligament, and underlying bone.

peripheral blood smear: a blood sample spread on a glass slide and stained for

analysis under a microscope. *Peripheral* refers to the use of circulating blood rather than tissue blood.

peripheral (puh-RIFF-er-ul) **nervous system:** the peripheral (outermost) part of the nervous system; the vast complex of wiring that extends from the central nervous system to the body's outermost areas. It contains both somatic and autonomic components.

peripheral parenteral nutrition (PPN): a type of nutrition support in which intravenous feedings are delivered into peripheral veins.

peripheral veins: small-diameter veins that carry blood from the arms and legs.

peristalsis (per-ih-STALL-sis): wavelike muscular contractions of the GI tract that push its contents along.

peritoneal (PEH-rih-toe-NEE-al) **dialysis:** a treatment that removes fluids and wastes from the blood by using the peritoneal membrane as a filter.

peritoneovenous (PEH-rih-toe-NEE-oh-VEE-nus) **shunt:** a surgical passage created between the peritoneum and the jugular vein to divert fluid and relieve ascites. The peritoneum is the membrane that surrounds the abdominal cavity.

peritonitis: inflammation of the peritoneal membrane, which lines the abdominal cavity.

pernicious (per-NISH-us) **anemia:** a blood disorder that reflects a vitamin B_{12} deficiency caused by lack of intrinsic factor and characterized by abnormally large and immature red blood cells. Other symptoms include muscle weakness and irreversible neurological damage.

persistent vegetative state (PVS): a vegetative mental state resulting from brain injury that persists for at least one month. Individuals lose awareness and the ability to think but retain noncognitive brain functions, such as motor reflexes and normal sleep patterns.

pH: the unit of measure expressing a substance's acidity or alkalinity.

phagocytes (FAG-oh-sites): white blood cells (primarily neutrophils and macrophages) that have the ability to engulf and destroy antigens.

phagocytosis (FAG-oh-sigh-TOE-sis): the process by which phagocytes engulf and destroy antigens.

pharynx (FAIR-inks): the passageway leading from the nose and mouth to the larynx and esophagus, respectively.

phenylketonuria (FEN-il-KEY-toe-NEW-ree-ah) or **PKU:** an inherited disorder characterized by failure to metabolize the amino acid phenylalanine to tyrosine.

phospholipid (FOS-foe-LIP-id): a compound similar to a triglyceride but having a phosphate group (a phosphorus-containing salt) and choline (or another nitrogen-containing compound) in place of one of the fatty acids.

phosphorus: a major mineral found mostly in the body's bones and teeth.

photosynthesis: the process by which green plants use the sun's energy to make carbohydrates from carbon dioxide and water.

physiological age: a person's age as estimated from her or his body's health and probable life expectancy.

phytic (FYE-tick) **acid:** a nonnutrient component of plant seeds; also called **phytate** (FYE-tate). Phytic acid occurs in the husks of grains, legumes, and seeds and is capable of binding minerals such as zinc, iron, calcium, magnesium, and copper in insoluble complexes in the intestine, which the body excretes unused.

phytochemicals (FIE-toe-KEM-ih-cals): nonnutrient compounds found in plant-derived foods that have biological activity in the body.

phytoestrogens: plant-derived compounds that have structural and functional similarities to human estrogen. Phytoestrogens include the isoflavones genistein, daidzein, and glycitein.

phytosterols: plant-derived compounds that have structural similarities to cholesterol and lower blood cholesterol by competing with cholesterol for absorption. Phytosterols include sterol esters and stanol esters.

pica (PIE-ka): a craving for nonfood substances. Also known as **geophagia** (gee-oh-FAY-gee-uh) when referring to clay eating and **pagophagia** (pag-oh-FAY-gee-uh) when referring to ice craving.

piggyback: the administration of a second solution using a separate port in an intravenous catheter.

pigment: a molecule capable of absorbing certain wavelengths of light so that it reflects only those that we perceive as a certain color.

placebo (pla-see-bo): an inert, harmless medication given to provide comfort and hope; a sham treatment used in controlled research studies.

placebo effect: a change that occurs in reponse to expectations in the effectiveness of a treatment that actually has no pharmaceutical effects.

placenta (plah-SEN-tuh): the organ that develops inside the uterus early in pregnancy, through which the fetus receives nutrients and oxygen and returns carbon dioxide and other waste products to be excreted.

plaque (PLACK): an accumulation of fatty deposits, smooth muscle cells, and fibrous connective tissue that develops in the artery walls in atherosclerosis. Plaque associated with atherosclerosis is known as **atheromatous** (ATH-er-OH-ma-tus) **plaque.**

plasminogen activator inhibitor-1: a protein that promotes blood clotting by inhibiting blood clot degradation within blood vessels.

point of unsaturation: the double bond of a fatty acid, where hydrogen atoms can easily be added to the structure.

polycystic kidney disease: a hereditary disorder characterized by the formation of multiple cysts in the kidneys.

polydipsia (POL-ee-DIP-see-ah): excessive thirst.

polypeptide: many (ten or more) amino acids bonded together.

polyphagia (POL-ee-FAY-jee-ah): excessive appetite or food intake.

polysaccharides: compounds composed of many monosaccharides linked together. An intermediate string of three to ten monosaccharides is an **oligosaccharide.**

polyunsaturated fatty acid (PUFA): a fatty acid that lacks four or more hydrogen atoms and has two or more double bonds between carbons—for example, linoleic acid (two double bonds) and linolenic acid (three double bonds).

polyuria (POL-ee-YOOR-ree-ah): excessive urine secretion.

portal hypertension: elevated blood pressure in the portal vein due to obstructed blood flow through the liver.

post term (infant): an infant born after the 42nd week of pregnancy.

postpartum amenorrhea: the normal temporary absence of menstrual periods immediately following childbirth.

potassium: the principal cation within the body's cells; critical to the maintenance of fluid balance, nerve impulse transmissions, and muscle contractions.

prebiotics: nondigestible substances in foods that stimulate the growth of probiotic bacteria within the large intestine.

precursors: substances that precede others; with regard to vitamins, compounds that can be converted into active vitamins; also known as **provitamins.**

prediabetes: the condition in which blood glucose levels are higher than normal but not high enough to be diagnosed as diabetes.

preeclampsia (PRE-ee-KLAMP-see-ah): a condition characterized by hypertension, fluid retention, and protein in the urine; formerly known as *pregnancy-induced hypertension*.

preformed vitamin A: dietary vitamin A in its active form.

prenatal alcohol exposure: subjecting a fetus to a pattern of excessive alcohol intake characterized by substantial regular use or heavy episodic drinking.

pressure gradient: the change in pressure over a given distance. In dialysis, a pressure gradient is created between the blood and the dialysate.

pressure sores: regions of damaged skin and tissue due to prolonged pressure on the

affected area by an external object, such as a bed, wheelchair, or cast; vulnerable areas of the body include buttocks, hips, and heels. Also called *decubitus* (deh-KYU-bih-tus) *ulcers.*

pressure ulcers: damage to the skin and underlying tissues as a result of compression and poor circulation; commonly seen in people who are bedridden or chairbound.

preterm (infant): an infant born prior to the 38th week of pregnancy; also called a **premature infant.** A **term** infant is born between the 38th and 42nd week of pregnancy.

primary deficiency: a nutrient deficiency caused by inadequate dietary intake of a nutrient.

primary hypertension: hypertension with an unknown cause; also known as **essential hypertension.**

probiotics: living microorganisms found in foods that, when consumed in sufficient quantities, are beneficial to health.

processed foods: foods that have been treated to change their physical, chemical, microbiological, or sensory properties.

progesterone: the hormone of gestation (pregnancy).

prolactin (pro-LAK-tin): a hormone secreted from the anterior pituitary gland that acts on the mammary glands to promote the production of milk. The release of prolactin is mediated by **prolactin-inhibiting hormone (PIH).**

proof: a way of stating the percentage of alcohol in distilled liquor. Liquor that is 100 proof is 50% alcohol; 90 proof is 45%, and so forth.

prooxidants: substances that significantly induce oxidative stress.

proteases (PRO-tee-aces): enzymes that hydrolyze protein.

protein digestibility: a measure of the amount of amino acids absorbed from a given protein intake.

protein efficiency ratio (PER): a measure of protein quality assessed by determining how well a given protein supports weight gain in growing rats; used to establish the protein quality for infant formulas and baby foods.

protein isolates: proteins that have been isolated from foods.

protein turnover: the degradation and synthesis of protein.

protein-energy malnutrition (PEM), also called **protein-kcalorie malnutrition (PCM):** a deficiency of protein, energy, or both, including kwashiorkor, marasmus, and instances in which they overlap (see p. 198).

protein-sparing action: the action of carbohydrate (and fat) in providing energy that allows protein to be used for other purposes.

proteins: compounds composed of carbon, hydrogen, oxygen, and nitrogen atoms, arranged into amino acids linked in a chain. Some amino acids also contain sulfur atoms.

proteinuria (PRO-teen-NOO-ree-ah): loss of protein, mostly albumin, in the urine; also known as *albuminuria.*

proton-pump inhibitors: a class of drugs that inhibit the enzyme that pumps hydrogen ions (protons) into the stomach. Examples include omeprazole (Prilosec) and lansoprazole (Prevacid).

puberty: the period in life in which a person becomes physically capable of reproduction.

public health dietitians: dietitians who specialize in providing nutrition services through organized community efforts.

public water: water from a municipal or county water system that has been treated and disinfected.

purified water: water that has been treated by distillation or other physical or chemical processes that remove dissolved solids. Because purified water contains no minerals or contaminants, it is useful for medical and research purposes.

purines: compounds of nitrogen-containing bases such as adenine, guanine, and caffeine. Purines that originate from the body are *endogenous* and those that derive from foods are *exogenous.*

pyloric (pie-LORE-ic) **sphincter:** the circular muscle that separates the stomach from the small intestine and regulates the flow of partially digested food into the small intestine; also called *pylorus* or *pyloric valve.*

pyloroplasty (pye-LORE-oh-PLAS-tee): surgery that enlarges the pyloric sphincter.

pyruvate (PIE-roo-vate): a 3-carbon compound that plays a key role in energy metabolism.

Q

qi gong (chee-GUNG): a Chinese system that combines movement, meditation, and breathing techniques and allegedly cures illness by enhancing the flow of qi (energy) within the body.

quality of life: a person's perceived physical and mental well-being.

R

radiation enteritis: inflammation of intestinal tissue caused by radiation therapy.

radiation therapy: the use of X-rays, gamma rays, or atomic particles to destroy cancer cells.

randomization (ran-dom-ih-zay-shun): a process of choosing the members of the experimental and control groups without bias.

raw sugar: the first crop of crystals harvested during sugar processing. Raw sugar cannot be sold in the United States because it contains too much filth (dirt, insect fragments, and the like). Sugar sold as "raw sugar" domestically has actually gone through over half of the refining steps.

RD: see *registered dietitian.*

rebound hyperglycemia: hyperglycemia that results from the release of counterregulatory hormones following nighttime hypoglycemia; also called the **Somogyi phenomenon.**

Recommended Dietary Allowance (RDA): the average daily amount of a nutrient considered adequate to meet the known nutrient needs of practically all healthy people; a goal for dietary intake by individuals.

rectum: the muscular terminal part of the intestine, extending from the sigmoid colon to the anus.

reduced kcalorie: at least 25% fewer kcalories per serving than the comparison food.

refeeding syndrome: a condition that sometimes develops when a severely malnourished person is aggressively fed; characterized by electrolyte and fluid imbalances and hyperglycemia.

reference protein: a standard against which to measure the quality of other proteins.

refined: the process by which the coarse parts of a food are removed. When wheat is refined into flour, the bran, germ, and husk are removed, leaving only the endosperm.

reflexology: a technique that applies pressure or massage on areas of the hands or feet to allegedly cure disease or relieve pain in other areas of the body; sometimes called *zone therapy.*

reflux: a backward flow.

reflux esophagitis: inflammation in the esophagus related to the reflux of acidic stomach contents.

registered dietitian (RD): a person who has completed a minimum of a bachelor's degree from an accredited university or college, has completed approved course work and a supervised practice program, has passed a national examination, and maintains registration through continuing professional education.

registration: listing; with respect to health professionals, listing with a professional organization that requires specific course work, experience, and passing of an examination.

relaxin: the hormone of late pregnancy.

remodeling: the dismantling and re-formation of a structure, in this case, bone.

renal (REE-nal): pertaining to the kidneys.

renal colic: the intense pain that occurs when a kidney stone passes through the ureter.

renal osteodystrophy: a bone disorder that develops in patients with chronic kidney disease as a consequence of increased secretion of parathyroid hormone, reduced serum calcium, acidosis, and impaired vitamin D activation by the kidneys.

renal threshold: the blood concentration of a substance that exceeds the kidneys' capacity for reabsorption, causing the substance to be passed into the urine.

renin (REN-in): an enzyme from the kidneys that activates angiotensin.

replication (REP-lih-KAY-shun)**:** repeating an experiment and getting the same results. The skeptical scientist, on hearing of a new, exciting finding, will ask, "Has it been replicated yet?" If it hasn't, the scientist will withhold judgment regarding the finding's validity.

requirement: the lowest continuing intake of a nutrient that will maintain a specified criterion of adequacy.

resection: the surgical removal of part of an organ or body structure.

resistant starches: starches that escape digestion and absorption in the small intestine of healthy people.

resistin (re-ZIST-in): a hormone produced by adipose cells that induces insulin resistance.

respiratory stress: abnormal gas exchange between the air and blood, resulting in lower-than-normal oxygen levels and higher-than-normal carbon dioxide levels.

resting metabolic rate (RMR): similar to the basal metabolic rate (BMR), a measure of the energy use of a person at rest in a comfortable setting, but with less stringent criteria for recent food intake and physical activity. Consequently, the RMR is slightly higher than the BMR.

reticulocytes: immature red blood cells released into blood by the bone marrow.

retina (RET-in-uh): the layer of light-sensitive nerve cells lining the back of the inside of the eye; consists of rods and cones.

retinoids (RET-ih-noyds): chemically related compounds with biological activity similar to that of retinol; metabolites of retinol.

retinol activity equivalents (RAE): a measure of vitamin A activity; the amount of retinol that the body will derive from a food containing preformed retinol or its precursor beta-carotene.

retinol-binding protein (RBP): the specific protein responsible for transporting retinol.

rheumatoid (ROO-ma-toyd) **arthritis:** a disease of the immune system involving painful inflammation of the joints and related structures.

rhodopsin (ro-DOP-sin): a light-sensitive pigment of the retina; contains the retinal form of vitamin A and the protein opsin.

riboflavin (RYE-boh-flay-vin): a B vitamin. The coenzyme forms are **FMN (flavin mononucleotide)** and **FAD (flavin adenine dinucleotide).**

rickets: the vitamin D–deficiency disease in children characterized by inadequate mineralization of bone (manifested in bowed legs or knock-knees, outward-bowed chest, and knobs on ribs). A rare type of rickets, not caused by vitamin D deficiency, is known as *vitamin D–refractory rickets*.

risk factor: a condition or behavior associated with an elevated frequency of a disease but not proved to be causal. Leading risk factors for chronic diseases include obesity, cigarette smoking, high blood pressure, high blood cholesterol, physical inactivity, and a diet high in saturated fats and low in vegetables, fruits, and whole grains.

RNA (ribonucleic acid): a compound similar to DNA, but RNA is a single strand with a ribose sugar instead of a deoxyribose sugar and uracil instead of thymine as one of its bases.

S

saccharin (SAK-ah-ren): an artificial sweetener that has been approved for use in the United States. In Canada, approval for use in foods and beverages is pending; currently available only in pharmacies and only as a tabletop sweetener, not as an additive.

saliva: the secretion of the salivary glands. Its principal enzyme begins carbohydrate digestion.

salivary glands: exocrine glands that secrete saliva into the mouth.

salt: a compound composed of a positive ion other than H^+ and a negative ion other than OH^-. An example is sodium chloride (Na^+ Cl^-).

salt sensitivity: a characteristic of individuals who respond to a high salt intake with an increase in blood pressure or to a low salt intake with a decrease in blood pressure.

sarcopenia (SAR-koh-PEE-nee-ah): loss of skeletal muscle mass, strength, and quality.

satiating: having the power to suppress hunger and inhibit eating.

satiation (say-she-AY-shun): the feeling of satisfaction and fullness that occurs during a meal and halts eating. Satiation determines how much food is consumed during a meal.

satiety (sah-TIE-eh-tee): the feeling of fullness and satisfaction that occurs after a meal and inhibits eating until the next meal. Satiety determines how much time passes between meals.

saturated fat-free: less than 0.5 g of saturated fat and 0.5 g of *trans* fat per serving.

saturated fatty acid: a fatty acid carrying the maximum possible number of hydrogen atoms—for example, stearic acid. A saturated fat is composed of triglycerides in which most of the fatty acids are saturated.

scurvy: the vitamin C–deficiency disease.

secondary deficiency: a nutrient deficiency caused by something other than an inadequate intake such as a disease condition or drug interaction that reduces absorption, accelerates use, hastens excretion, or destroys the nutrient.

secondary hypertension: hypertension that results from a known physiological abnormality.

secretin (see-CREET-in): a hormone produced by cells in the duodenum wall. Target organ: the pancreas. Response: secretion of bicarbonate-rich pancreatic juice.

segmentation (SEG-men-TAY-shun): a periodic squeezing or partitioning of the intestine at intervals along its length by its circular muscles.

selective menus: menus that provide choices in some or all menu categories.

selenium (se-LEEN-ee-um): a trace element.

self-monitoring of blood glucose: home monitoring of blood glucose levels using a glucose meter.

semipermeable membrane: a membrane that allows some particles to pass through, but not others.

semiselective menus: menus that combine aspects of both selective and nonselective menus.

senile dementia: the loss of brain function beyond the normal loss of physical adeptness and memory that occurs with aging.

senile plaques: clumps of the protein fragment beta-amyloid on the nerve cells, commonly found in the brains of people with Alzheimer's dementia.

sepsis: an acute inflammatory response caused by infection; characterized by symptoms similar to those of SIRS.

serotonin (SER-oh-TONE-in): a neurotransmitter important in sleep regulation, appetite control, intestinal motility, obsessive-compulsive behaviors, and mood disorders. Serotonin is synthesized in the body from the amino acid tryptophan with the help of vitamin B_6.

set point: the point at which controls are set (for example, on a thermostat). The set-point theory that relates to body weight proposes that the body tends to maintain a certain weight by means of its own internal controls.

shock: a severe reduction in blood flow that deprives the body's tissues of oxygen and nutrients; characterized by reduced blood pressure, raised heart and respiratory rates, and muscle weakness.

shock-wave lithotripsy: a nonsurgical procedure that uses high-amplitude sound waves to fragment gallstones.

short bowel syndrome: the malabsorption syndrome that follows resection of the small intestine, which results in insufficient absorptive capacity in the remaining intestine.

sibutramine (sigh-BYOO-tra-mean): a drug used in the treatment of obesity that slows the reabsorption of serotonin in the brain, thus suppressing appetite and creating a feeling of fullness.

sickle-cell anemia: a hereditary form of anemia characterized by abnormal sickle- or crescent-shaped red blood cells. Sickled cells interfere with oxygen transport and blood flow. Symptoms are precipitated by dehydration

and insufficient oxygen (as may occur at high altitudes) and include hemolytic anemia (red blood cells burst), fever, and severe pain in the joints and abdomen.

simple carbohydrates (sugars): monosaccharides and disaccharides.

sinusoids: the small, capillary-like passages that carry blood through liver tissue.

Sjögren's syndrome: an autoimmune disease characterized by the destruction of secretory glands, especially those that produce saliva and tears, resulting in dry mouth and dry eyes.

sludge: literally, a semisolid mass. Biliary sludge is made up of mucus, cholesterol crystals, and bilirubin granules.

small intestine: a 10-foot length of small-diameter intestine that is the major site of digestion of food and absorption of nutrients. Its segments are the duodenum, jejunum, and ileum.

soaps: chemical compounds that form between fatty acids and positively charged minerals.

sodium: the principal cation in the extracellular fluids of the body; critical to the maintenance of fluid balance, nerve impulse transmissions, and muscle contractions.

sodium-free and **salt-free:** less than 5 mg of sodium per serving.

soft water: water with a high sodium or potassium content.

soluble fibers: indigestible food components that dissolve in water to form a gel. An example is pectin from fruit, which is used to thicken jellies.

solutes (SOLL-yutes): the substances that are dissolved in a solution. The number of molecules in a given volume of fluid is the **solute concentration**.

somatic (so-MAT-ick) **nervous system:** the division of the nervous system that controls the voluntary muscles, as distinguished from the autonomic nervous system, which controls involuntary functions.

somatostatin (GHIH): a hormone that inhibits the release of growth hormone; the opposite of somatotropin (GH).

soup kitchens: programs that provide prepared meals to be eaten on site.

spasm: a sudden, forceful, and involuntary muscle contraction.

specialized formulas: enteral formulas designed to meet the nutrient needs of patients with specific illnesses; also called *disease-specific formulas.*

sperm: the male reproductive cell, capable of fertilizing an ovum.

sphincter (SFINK-ter): a circular muscle surrounding, and able to close, a body opening. Sphincters are found at specific points along the GI tract and regulate the flow of food particles.

spina (SPY-nah) **bifida** (BIFF-ih-dah): one of the most common types of neural tube defects; characterized by the incomplete closure of the spinal cord and its bony encasement.

spring water: water originating from an underground spring or well. It may be bubbly (carbonated), or "flat" or "still," meaning not carbonated. Brand names such as "Spring Pure" do not necessarily mean that the water comes from a spring.

standard diet: a diet that includes all foods and meets the nutrient needs of healthy people; also called a *regular diet.*

standard formulas: enteral formulas that contain mostly intact proteins and polysaccharides; also called *polymeric formulas.*

starches: plant polysaccharides composed of glucose.

steatohepatitis (STEE-ah-to-HEP-ah-TIE-tis): liver inflammation that is associated with fatty liver.

steatorrhea (stee-AT-or-REE-ah): excessive fat in the stools resulting from fat malabsorption; characterized by stools that are loose, frothy, and foul smelling due to a high fat content.

sterile: free of microorganisms, such as bacteria.

sterols (STARE-ols or STEER-ols): compounds containing a four ring carbon structure with any of a variety of side chains attached.

stevia (STEE-vee-ah): a South American shrub whose leaves are used as a sweetener; sold in the United States as a dietary supplement that provides sweetness without kcalories.

stoma (STOE-ma): a surgical opening made in the abdominal wall.

stomach: a muscular, elastic, saclike portion of the digestive tract that grinds and churns swallowed food, mixing it with acid and enzymes to form chyme.

stools: waste matter discharged from the colon; also called feces (FEE-seez).

stress: any threat to a person's well-being; a demand placed on the body to adapt.

stress fractures: bone damage or breaks caused by stress on bone surfaces during exercise.

stress response: the chemical and physical changes that occur within the body during stress.

stressors: environmental elements, physical or psychological, that cause stress.

stricture: abnormal narrowing of a passageway; often due to inflammation, scarring, or a congenital abnormality.

stroke: a sudden injury to brain tissue resulting from impaired blood flow through an artery that supplies blood to the brain; also called a *cerebrovascular accident*.

structure-function claims: statements that characterize the relationship between a nutrient or other substance in a food and its role in the body.

struvite (STROO-vite): crystals of magnesium ammonium phosphate.

subclavian (sub-KLAY-vee-an) **vein:** the vein that provides passageway from the lymphatic system to the vascular system.

subclinical deficiency: a deficiency in the early stages, before the outward signs have appeared.

subcutaneous (sub-cue-TAY-nee-us): beneath the skin.

subjects: the people or animals participating in a research project.

successful weight-loss maintenance: achieving a weight loss of at least 10% of initial body weight and maintaining the loss for at least one year.

sucralose (SUE-kra-lose): an artificial sweetener approved for use in the United States and Canada.

sucrase: an enzyme that hydrolyzes sucrose

sucrose (SUE-krose): a disaccharide composed of glucose and fructose; commonly known as table sugar, beet sugar, or cane sugar. Sucrose also occurs in many fruits and some vegetables and grains.

sudden infant death syndrome (SIDS): the unexpected and unexplained death of an apparently well infant; the most common cause of death of infants between the second week and the end of the first year of life; also called *crib death.*

sugar replacers: sugarlike compounds that can be derived from fruits or commercially produced from dextrose; also called **sugar alcohols** or **polyols.** Sugar alcohols are absorbed more slowly than other sugars and metabolized differently in the human body; they are not readily utilized by ordinary mouth bacteria. Examples are **maltitol, mannitol, sorbitol, xylitol, isomalt,** and **lactitol.**

sugar-free: less than 0.5 g of sugar per serving.

sulfate: the oxidized form of sulfur.

sulfur: a mineral present in the body as part of some proteins.

supplement: any pill, capsule, tablet, liquid, or powder that contains vitamins, minerals, herbs, or amino acids; intended to increase dietary intake of these substances.

surrogate: a substitute; a person who takes the place of another.

sushi: vinegar-flavored rice and seafood, typically wrapped in seaweed and stuffed with colorful vegetables. Some sushi is stuffed with raw fish; other varieties contain cooked seafood.

syringes: devices used for injecting medications. A syringe consists of a hypodermic needle attached to a hollow tube with a plunger inside.

systemic (sih-STEM-ic): relating to the entire body.

systemic inflammatory response syndrome (SIRS): a whole-body response to acute inflammation; characterized by raised heart and respiratory rates, abnormal white blood cell counts, and abnormal body temperature.

T

T cell: a lymphocyte that attacks antigens; functions in cell-mediated immunity.

tagatose (TAG-ah-tose): a monosaccharide structurally similar to fructose that is incompletely absorbed and thus provides only 1.5 kcalories per gram; approved for use as a "generally recognized as safe" ingredient.

TCA cycle or **tricarboxylic** (try-car-box-ILL-ick) **acid cycle:** a series of metabolic reactions that break down molecules of acetyl CoA to carbon dioxide and hydrogen atoms; also called the **Kreb's cycle** after the biochemist who elucidated its reactions.

tempeh (TEM-pay): a fermented soybean food, rich in protein and fiber.

teratogenic (ter-AT-oh-jen-ik): causing abnormal fetal development and birth defects.

testosterone: a steroid hormone from the testicles, or testes. The steroids, as explained in Chapter 5, are chemically related to, and some are derived from, the lipid cholesterol.

textured vegetable protein: processed soybean protein used in vegetarian products such as soy burgers; see also *meat replacements.*

theory: a tentative explanation that integrates many and diverse findings to further the understanding of a defined topic.

therapeutic touch: a technique of passing hands over a patient to purportedly identify energy imbalances and transfer healing power from therapist to patient; also called *laying on of hands.*

thermic effect of food (TEF): an estimation of the energy required to process food (digest, absorb, transport, metabolize, and store ingested nutrients); also called the **specific dynamic effect (SDE)** of food or the **specific dynamic activity (SDA)** of food. The sum of the TEF and any increase in the metabolic rate due to overeating is known as **diet-induced thermogenesis (OIT).**

thermogenesis: the generation of heat; used in physiology and nutrition studies as an index of how much energy the body is expending.

thiamin (THIGH-ah-min): a B vitamin. The coenzyme form is **TPP (thiamin pyrophosphate).**

thirst: a conscious desire to drink.

thoracic (thor-ASS-ic) **duct:** the main lymphatic vessel that collects lymph and drains into the left subclavian vein.

thrombosis (throm-BOH-sis): the formation or presence of a blood clot in blood vessels. A *coronary thrombosis* occurs in a coronary artery, and a *cerebral thrombosis* occurs in an artery that supplies blood to the brain.

thrombus: a blood clot formed within a blood vessel that remains attached to its place of origin.

thrush: a fungal infection of the mouth and throat, most often caused by *Candida albicans.*

thyroid-stimulating hormone (TSH): a hormone secreted by the pituitary that stimulates the thyroid gland to secrete its hormones—thyroxine and triiodothyronine. The release of TSH is mediated by TSH-releasing hormone (TRH).

tissue rejection: destruction of donor tissue by the recipient's immune system, which recognizes the donor cells as foreign.

tocopherol (tuh-KOFF-er-ol): a general term for several chemically related compounds, one of which has vitamin E activity. (See Appendix C for chemical structures.)

tofu (TOE-foo): a curd made from soybeans, rich in protein and often fortified with calcium; used in many Asian and vegetarian dishes in place of meat.

Tolerable Upper Intake Level (UL): the maximum daily amount of a nutrient that appears safe for most healthy people and beyond which there is an increased risk of adverse health effects.

tolerance level: the maximum amount of residue permitted in a food when a pesticide is used according to the label directions.

total nutrient admixture (TNA): a parenteral solution that contains dextrose, amino acids, and lipids; also called a **3-in-1 solution** or an **all-in-one solution.**

total parenteral nutrition (TPN): a type of nutrition support in which intravenous feedings are delivered into a central vein.

trabecular (tra-BECK-you-lar) **bone:** the lacy inner structure of calcium crystals that supports the bone's structure and provides a calcium storage bank.

trace minerals: essential mineral nutrients found in the human body in amounts smaller than 5 g; sometimes called **microminerals.**

trachea (TRAKE-ee-uh): the air passageway from the larynx to the lungs; also called the *windpipe.*

traditional Chinese medicine (TCM): an approach to medical care based on the concept that illness can be cured by enhancing the flow of qi (energy) within a person's body. Treatments may include herbal therapies, physical exercises, meditation, acupuncture, and remedial massage.

***trans* fat-free:** less than 0.5 g of *trans* fat and less than 0.5 g of saturated fat per serving.

***trans*-fatty acids:** fatty acids with hydrogens on opposite sides of the double bond.

transamination (TRANS-am-ih-NAY-shun): the transfer of an amino group from one amino acid to a keto acid, producing a new nonessential amino acid and a new keto acid.

transferrin (trans-FAIR-in): the iron transport protein.

transient hypertension of pregnancy: high blood pressure that develops in the second half of pregnancy and resolves after childbirth, usually without affecting the outcome of the pregnancy.

transient ischemic attacks (TIAs): brief ischemic strokes that cause short-term neurological symptoms.

transnasal: through the nose. A *transnasal feeding tube* is one that is inserted through the nose.

triglycerides (try-GLISS-er-rides): the chief form of fat in the diet and the major storage form of fat in the body; composed of a molecule of glycerol with three fatty acids attached; also called *triacylglycerols* (try-ay-seel-GLISS-er-ols).

tripeptide: three amino acids bonded together.

tube feedings: liquid formulas delivered through a tube placed in the stomach or intestine.

tubules: tubelike structures of the nephron that process filtrate during urine production. The tubules are surrounded by capillaries that reabsorb substances retained by tubule cells.

tumor: an abnormal tissue mass that has no physiological function; also called a *neoplasm* (NEE-oh-plazm).

turbinado (ter-bih-NOD-oh) **sugar:** sugar produced using the same refining process as white sugar, but without the bleaching and anti-caking treatment. Traces of molasses give turbinado its sandy color.

type 1 diabetes: the type of diabetes that accounts for 5 to 10% of diabetes cases and usually results from autoimmune destruction of pancreatic beta cells and failure to produce insulin.

type 2 diabetes: the type of diabetes that accounts for 90 to 95% of diabetes cases and usually results from insulin resistance coupled with insufficient insulin secretion.

type I osteoporosis: osteoporosis characterized by rapid bone losses, primarily of trabecular bone.

type II osteoporosis: osteoporosis characterized by gradual losses of both trabecular and cortical bone.

U

ulcer: a lesion of the skin or mucous membranes characterized by inflammation and damaged tissues. See also *peptic ulcer.*

ulcerative colitis (ko-LY-tis): an inflammatory bowel disease that involves the colon. Inflammation affects the mucosa and submucosa of the intestinal wall.

ultrafiltration: removal of fluids and solutes from blood by using pressure to transfer the blood across a semipermeable membrane.

umbilical (um-BILL-ih-cul) **cord:** the ropelike structure through which the fetus's veins and arteries reach the placenta; the route of nourishment and oxygen to the fetus and the route of waste disposal from the fetus. The scar in the middle of the abdomen that marks the former attachment of the umbilical cord is the **umbilicus** (um-BILL-ih-cus), commonly known as the "belly button."

undernutrition: deficient energy or nutrients.

underweight: body weight below some standard of acceptable weight that is usually defined in relation to height (such as BMI); BMI below 18.5.

unsaturated fatty acid: a fatty acid that lacks hydrogen atoms and has at least one double bond between carbons (includes monounsaturated and polyunsaturated fatty acids). An **unsaturated fat** is composed of triglycerides in which most of the fatty acids are unsaturated.

unspecified eating disorders: eating disorders that do not meet the defined criteria for specific eating disorders.

urea (you-REE-uh): the principal nitrogen-excretion product of protein metabolism. Two ammonia fragments are combined with carbon dioxide to form urea.

urea kinetic modeling: a method of determining the adequacy of dialysis treatment by calculating the urea clearance from blood.

uremia (you-REE-me-ah): the abnormal accumulation of nitrogen-containing substances, especially urea, in the blood; also called *azotemia* (AZE-oh-TEE-me-ah).

uremic syndrome: the cluster of symptoms associated with a GFR below 15 mL/min, including uremia, anemia, bone disease, hormonal imbalances, bleeding impairment, increased cardiovascular disease risk, and reduced immunity.

uterus (YOU-ter-us): the muscular organ within which the infant develops before birth.

V

vagotomy (vay-GOT-oh-mee): surgery that severs the vagus nerve in order to suppress gastric acid secretion. This surgery may require a follow-up *pyloroplasty* procedure to allow stomach drainage.

vagus nerve: the cranial nerve that regulates hydrochloric acid secretion and peristalsis. Effects elsewhere in the body include regulation of heart rate and bronchiole constriction.

validity (va-lid-ih-tee): having the quality of being founded on fact or evidence.

variables: factors that change. A variable may depend on another variable (for example, a child's height depends on his age), or it may be independent (for example, a child's height does not depend on the color of her eyes). Sometimes both variables correlate with a third variable (a child's height and eye color both depend on genetics).

varices (VAH-rih-seez): abnormally dilated blood vessels (singular: *varix*).

variety (dietary): eating a wide selection of foods within and among the major food groups.

vasoconstrictor (VAS-oh-kon-STRIK-tor): a substance that constricts or narrows the blood vessels.

vegans (VEE-gans): people who exclude all animal-derived foods (including meat, poultry, fish, eggs, and dairy products) from their diets; also called **pure vegetarians, strict vegetarians,** or **total vegetarians.**

vegetarians: a general term used to describe people who exclude meat, poultry, fish, or other animal-derived foods from their diets.

veins (VANES): vessels that carry blood to the heart.

very low sodium: 35 mg or less per serving.

villi (VILL-ee, or VILL-eye): fingerlike projections from the folds of the small intestine; singular **villus.**

viscous: a gel-like consistency.

vitamin A: all naturally occurring compounds with the biological activity of retinol (RET-ih-nol), the alcohol form of vitamin A.

vitamin A activity: a term referring to both the active forms of vitamin A and the precursor forms in foods without distinguishing between them.

vitamin B_6: a family of compounds—pyridoxal, pyridoxine, and pyridoxamine. The primary active coenzyme form is **PLP (pyridoxal phosphate).**

vitamin B_{12}: a B vitamin characterized by the presence of cobalt (see Figure 13-12, p. 462). The active forms of coenzyme B_{12} are **methylcobalamin** and **deoxyadenosylcobalamin.**

vitamins: organic, essential nutrients required in small amounts by the body for health.

VLDL (very-low-density lipoprotein): the type of lipoprotein made primarily by liver cells to transport lipids to various tissues in the body; composed primarily of triglycerides.

vomiting: expulsion of the contents of the stomach up through the esophagus to the mouth.

vulnerable plaque: a form of plaque, susceptible to rupture, that is lipid-rich and has only a thin, fibrous barrier between the arterial lumen and the plaque's lipid core.

W

waist circumference: an anthropometric measurement used to assess a person's abdominal fat.

wasting: the gradual atrophy (loss) of body tissues; associated with protein-energy malnutrition or chronic illness.

water balance: the balance between water intake and output (losses).

water intoxication: the rare condition in which body water contents are too high in all body fluid compartments.

wean: to gradually replace breast milk with infant formula or other foods appropriate to an infant's diet.

websites: Internet resources composed of text and graphic files, each with a unique URL (Uniform Resource Locator) that names the site (for example, www.usda.gov).

weight management: maintaining body weight in a healthy range by preventing gradual weight gain over time and losing weight if overweight.

well water: water drawn from ground water by tapping into an aquifer.

Wernicke-Korsakoff (VER-nee-key KORE-sah-kof) **syndrome:** a neurological disorder typically associated with chronic alcoholism and caused by a deficiency of the B vitamin thiamin; also called *alcohol-related dementia.*

wheat gluten (GLU-ten): a family of water-insoluble proteins in wheat; includes the gliadin (GLY-ah-din) proteins that are toxic to persons with celiac disease.

whey protein: a by-product of cheese production; falsely promoted as increasing muscle mass. Whey is the watery part of milk that separates from the curds.

white sugar: pure sucrose or "table sugar," produced by dissolving, concentrating, and recrystallizing raw sugar.

whole grain: a grain milled in its entirety (all but the husk), not refined.

wine: an alcoholic beverage made by fermenting grape juice.

World Wide Web (the web, commonly abbreviated **www**): a graphical subset of the Internet.

X

xanthophylls (ZAN-tho-fills): pigments found in plants; responsible for the color changes seen in autumn leaves.

xerophthalmia (zer-off-THAL-mee-uh): progressive blindness caused by severe vitamin A deficiency.

xerosis (zee-ROW-sis): abnormal drying of the skin and mucous membranes; a sign of vitamin A deficiency.

xerostomia: dry mouth caused by reduced salivary flow.

Y

yogurt: milk product that results from the fermentation of lactic acid in milk by *Lactobacillus bulgaricus* and *Streptococcus thermophilus.*

Z

Zollinger-Ellison syndrome: a condition characterized by the presence of gastrin-secreting tumors in the duodenum or pancreas.

zygote (ZY-goat): the product of the union of ovum and sperm; so-called for the first two weeks after fertilization.

Index

Page references in **bold** indicate definitions of terms. (*See also* Glossary, GL-1 to GL-26)

Page references followed by the letter "f" indicate figures.

Page references followed by the letter "t" indicate tables.

Page references followed by the letter "n" indicate footnotes.

Page references consisting of a single letter (A, B, C or X, Y, Z) refer to the inside front and back covers respectively.

Page references with combined letter and number (A-1) refer to the appendixes.

Aids to Calculation

Many mathematical problems have been worked out in the "How to" sections of the text and practice problems have been provided in the "Nutrition Calculations" sections at the end of some chapters. These pages offer additional help and examples.

Conversions

A conversion factor is a fraction that converts a measurement expressed in one unit to another unit—for example, from pounds to kilograms or from feet to meters. To create a conversion factor, an equality (such as 1 kilogram = 2.2 pounds) is expressed as a fraction:

$$\frac{1 \text{ kg}}{2.2 \text{ lb}} \text{ and } \frac{2.2 \text{ lb}}{1 \text{ kg}}$$

To convert the units of a measurement, use the fraction with the desired unit in the numerator.

Example 1: Convert a weight of 130 pounds to kilograms. Multiply 130 pounds by the conversion factor that includes both pounds and kilograms, with the desired unit (kilograms) in the numerator:

$$130 \text{ lb} \times \frac{1 \text{ kg}}{2.2 \text{ lb}} = \frac{130 \text{ kg}}{2.2} = 59 \text{ kg}$$

Alternatively, to convert a measurement from one unit of measure to another, multiply the given measurement by the appropriate equivalent found in the accompanying table of weights and measures.

Example 2: Convert 64 fluid ounces to liters.
Locate the equivalent measure from the table (1 ounce = 0.03 liter) and multiply the number of ounces by 0.03:

$$64 \text{ oz} \times 0.03 \text{ oz/L} = 1.9 \text{ L}$$

Percentages

A percentage is a fraction whose denominator is 100. For example:

$$50\% = \frac{50}{100}$$

Like other fractions, percentages are used to express a portion of a quantity. Fractions whose denominators are numbers other than 100 can be converted to percentages by first dividing the numerator by the denominator and then multiplying the result by 100.

Example 3: Express $^5/_8$ as a percent.

$$\frac{5}{8} = 5 \div 8 = 0.625$$

$$0.625 \times 100 = 62.5\%$$

The following examples show how to calculate specific percentages.

Example 4: Suppose your energy intake for the day is 2000 kcalories (kcal) and your recommended energy intake is 2400 kcalories. What percent of the recommended energy intake did you consume?

Divide your intake by the recommended intake.
2000 kcal (intake) ÷ 2400 kcal (recommended) = 0.83

Multiply by 100 to express the decimal as a percent.
0.83 × 100 = 83%

Example 5: Suppose a man's intake of vitamin C is 120 milligrams and his RDA is 90 milligrams. What percent of the RDA for vitamin C did he consume?

Divide the intake by the recommended intake.
120 mg (intake) ÷ 90 mg (RDA) = 1.33

Multiply by 100 to express the decimal as a percent.
1.33 × 100 = 133%

Example 6: Dietary recommendations suggest that carbohydrates provide 45 to 65 percent of the day's energy intake. If your energy intake is 2000 kcalories, how much carbohydrate should you eat?

Because this question has a range of acceptable answers, work the problem twice. First, use 45% to find the least amount you should eat.

Divide 45 by 100 to convert to a decimal.
45 ÷ 100 = 0.45

Multiply kcalories by 0.45.
2000 kcal × 0.45 = 900 kcal

Divide kcalories by 4 to convert carbohydrate kcal to grams.
900 kcal ÷ 4 kcal/g = 225 g

Now repeat the process using 65% to find the maximum number of grams of carbohydrates you should eat.

Divide 65 by 100 to convert it to a decimal.
65 ÷ 100 = 0.65

Multiply kcalories by 0.65.
2000 kcal × 0.65 = 1300 kcal

Divide kcalories by 4 to convert carbohydrate kcal to grams.
1300 kcal ÷ 4 kcal/g = 325 g

If you plan for between 45% and 65% of your 2000-kcalorie intake to be from carbohydrates, you should eat between 225 grams and 325 grams of carbohydrates.

Weights and Measures

LENGTH

1 centimeter (cm) = 0.39 inches (in)
1 foot (ft) = 30 centimeters (cm)
1 inch (in) = 2.54 centimeters (cm)
1 meter (m) = 39.37 inches (in)

WEIGHT

1 gram (g) = 0.001 kilogram (kg)
= 1000 milligram (mg)
= .035 ounce (oz)
1 kilogram (kg) = 1000 grams (g)
= 2.2 pounds (lb)
1 microgram (µg) = 0.001 milligram (mg)
1 milligram (mg) = 0.001 gram (g)
= 1000 microgram (µg)
1 ounce (oz) = 28 grams (g)
= 0.03 kilograms (kg)
1 pound (lb) = 454 grams (g)
= 0.45 kilograms (kg)
= 16 ounces (oz)

VOLUME

1 cup = 16 tablespoons (tbs or T)
= 0.25 liter (L)
= 236 milliliters (mL, commonly rounded to 250 mL)
= 8 ounces (oz)
1 liter (L) = 33.8 fluid ounces (fl oz)
= 0.26 gallons (gal)
= 2.1 pints (pt)
= 1.06 quarts (qt)
= 1000 milliliters (mL)
1 milliliter (mL) = 0.001 liter (L)
= 0.03 fluid ounces (fl oz)
1 ounce (oz) = 0.03 liter (L)
= 30 milliliters (mL)
1 pint (pt) = 2 cups (c)
= 0.47 liters (L)
= 16 ounces (oz)
1 quart (qt) = 4 cups (c)
= 0.95 liters (L)
= 32 ounces (oz)
1 tablespoon (tbs or T) = 3 teaspoons (tsp)
=15 milliliters (mL)
1 teaspoon (tsp) = 5 milliliters (mL)
1 gallon (gal) = 16 cups (c)
= 3.8 liters (L)
= 128 ounces (oz)

ENERGY

1 millijoule (mJ) = 240 kcalories (kcal)
1 kilojoule (kJ) = 0.24 kcalories (kcal)
1 kcalorie (kcal) = 4.2 kilojoule (kJ)
1 g alcohol = 7 kcal = 29 kJ
1 g carbohydrate = 4 kcal = 17 kJ
1 g fat = 9 kcal = 37 kJ
1 g protein = 4 kcal = 17 kJ

TEMPERATURE

To change from Fahrenheit (°F) to Celsius (°C), subtract 32 from the Fahrenheit measure and then multiply that result by 0.56.

To change from Celsius (°C) to Fahrenheit (°F), multiply the Celsius measure by 1.8 and add 32 to that result.

A comparison of some useful temperatures is given below.

	Celsius	Fahrenheit
Boiling point	100°C	212°F
Body temperature	37°C	98.6°F
Freezing point	0°C	32°F

Daily Values for Food Labels

The Daily Values are standard values developed by the Food and Drug Administration (FDA) for use on food labels. The values are based on 2000 kcalories a day for adults and children over 4 years old. Chapter 2 provides more details.

Nutrient	Amount
Protein[a]	50 g
Thiamin	1.5 mg
Riboflavin	1.7 mg
Niacin	20 mg NE
Biotin	300 µg
Pantothenic acid	10 mg
Vitamin B_6	2 mg
Folate	400 µg
Vitamin B_{12}	6 µg
Vitamin C	60 mg
Vitamin A	5000 IU[b]
Vitamin D	400 IU[b]
Vitamin E	30 IU[b]
Vitamin K	80 µg
Calcium	1000 mg
Iron	18 mg
Zinc	15 mg
Iodine	150 µg
Copper	2 mg
Chromium	120 µg
Selenium	70 µg
Molybdenum	75 µg
Manganese	2 mg
Chloride	3400 mg
Magnesium	400 mg
Phosphorus	1000 mg

[a]The Daily Values for protein vary for different groups of people: pregnant women, 60 g; nursing mothers, 65 g; infants under 1 year, 14 g; children 1 to 4 years, 16 g.
[b]Equivalent values for nutrients expressed as IU are: vitamin A, 1500 RAE (assumes a mixture of 40% retinol and 60% beta-carotene); vitamin D, 10 µg; vitamin E, 20 mg.

Food Component	Amount	Calculation Factors
Fat	65 g	30% of kcalories
Saturated fat	20 g	10% of kcalories
Cholesterol	300 mg	Same regardless of kcalories
Carbohydrate (total)	300 g	60% of kcalories
Fiber	25 g	11.5 g per 1000 kcalories
Protein	50 g	10% of kcalories
Sodium	2400 mg	Same regardless of kcalories
Potassium	3500 mg	Same regardless of kcalories

GLOSSARY OF NUTRIENT MEASURES

kcal: kcalories; a unit by which energy is measured (Chapter 1 provides more details).

g: grams; a unit of weight equivalent to about 0.03 ounces.

mg: milligrams; one-thousandth of a gram.

µg: micrograms; one-millionth of a gram.

IU: international units; an old measure of vitamin activity determined by biological methods (as opposed to new measures that are determined by direct chemical analyses). Many fortified foods and supplements use IU on their labels.
- For vitamin A, 1 IU = 0.3 µg retinol, 3.6 µg β-carotene, or 7.2 µg other vitamin A carotenoids
- For vitamin D, 1 IU = 0.02 µg cholecalciferol
- For vitamin E, 1 IU = 0.67 natural α-tocopherol (other conversion factors are used for different forms of vitamin E)

mg NE: milligrams niacin equivalents; a measure of niacin activity (Chapter 10 provides more details).
- 1 NE = 1 mg niacin
  = 60 mg tryptophan (an amino acid)

µg DFE: micrograms dietary folate equivalents; a measure of folate activity (Chapter 10 provides more details).
- 1 µg DFE = 1 µg food folate
  = 0.6 µg fortified food or supplement folate taken with food
  = 0.5 µg supplement folate taken on an empty stomach

µg RAE: micrograms retinol activity equivalents; a measure of vitamin A activity (Chapter 11 provides more details).
- 1 µg RAE = 1 µg retinol
  = 12 µg β-carotene
  = 24 µg other vitamin A carotenoids

mmol: millimoles; one-thousanth of a mole, the molecular weight of a substance. To convert mmol to mg, multiply by the atomic weight of the substance.
- For sodium, mmol × 23 = mg Na
- For chloride, mmol × 35.5 = mg Cl
- For sodium chloride, mmol × 58.5 = mg NaCl

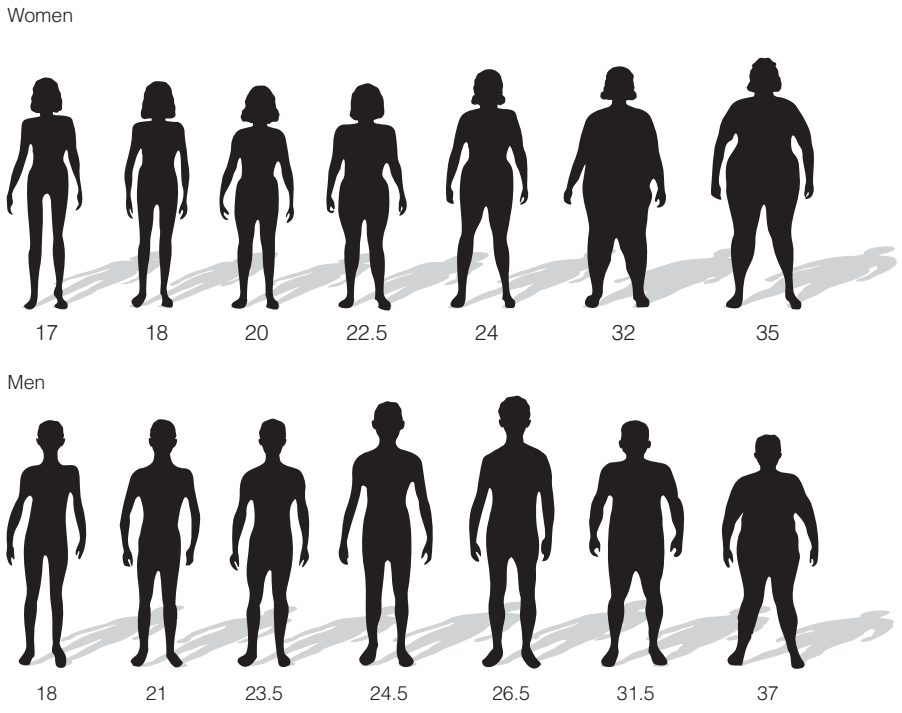
	Under-weight	Healthy Weight						Overweight					Obese										
	(<18.5)	(18.5–24.9)						(25–29.9)					(≥30)										

Find your height along the left-hand column and look across the row until you find the number that is closest to your weight. The number at the top of that column identifies your BMI. Chapter 8 describes how BMI correlates with disease risks and defines obesity, and Chapter 16 presents BMI for children and adolescents. The area shaded in blue represents healthy weight ranges. The figure below presents silhouettes of various BMI.



SOURCE: Reprinted from material of the Dietitians of Canada.
